Medical knowledge and practice change constantly. This book is designed to provide accurate, authoritative information about the subject matter in question. However, readers are advised to check the most current information available on procedures included and check information from the manufacturer of each product to be administered, to verify the recommended dose, formula, method and duration of administration, adverse effects and contraindications. It is the responsibility of the practitioner to take all appropriate safety precautions. Neither the publisher nor the author(s)/editor(s) assume any liability for any injury and/or damage to persons or property arising from or related to use of material in this book.

This book is sold on the understanding that the publisher is not engaged in providing professional medical services. If such advice or services are required, the services of a competent medical professional should be sought.

Every effort has been made where necessary to contact holders of copyright to obtain permission to reproduce copyright material. If any have been inadvertently overlooked, the publisher will be pleased to make the necessary arrangements at the first opportunity.

# Preface

---

In the last decade, many textbooks of pediatrics have been published in India. However, most were targeted towards undergraduates and general practitioners. The number of students opting for postgraduate courses in pediatrics is on the rise. Currently, most postgraduates in pediatrics augment their knowledge by reading and referencing to textbooks published abroad. Many of the Western textbooks are very detailed and provide an important amalgamation of clinical pediatrics with the major advances in genetics, genomics, physiology, diagnosis, imaging, and therapeutics. However, the “state-of-the-art” on the care of the normal and ill neonate, child, or adolescent as presented in these textbooks differ from that practiced in India or South Asia. While these books provide a detailed description of most disorders seen in children, they unfortunately do not provide both evidence-based medicine and astute personal clinical experiences from India. The focus is missing on the core issues relevant in the Indian context, i.e., growth, nutrition, immunization, development, newborn and adolescent health, and programmatic and social issues in child health. The need for a comprehensive postgraduate textbook, which can be adapted to Indian needs, has been recognized and expressed for some time now.

Rapid strides in medicine and technological advances in biological sciences were witnessed in the last decade. Advances in preventive and therapeutic care have opened new prospects for care of children. However, substantial improvements in quality of life have been limited to those with access to healthcare. Poverty, ignorance, war, bioterrorism, misplaced priorities and the lack of political will have prevented many children throughout the world, benefitting from these significant advances. Despite advances in infectious diseases, newer vaccines and preventive neonatal care, mortality and morbidity continue to be unacceptably high. Our priorities for care of children are often different from the developed world. Also, medical advances and good clinical practice must always be coupled with effective advocacy. These aspects need to be addressed in a postgraduate textbook, as current postgraduates are the future decision makers in our country.

It is our earnest wish and hope that the postgraduate textbook will help to fill the long-felt vacuum. It attempts to provide the essential information that postgraduates throughout India need to capture to effectively address the health problems that our children and youth may face in the times to come. Our objective is to be comprehensive yet concise and reader friendly, embracing both the new advances in science as well as the time-honored art of pediatric practice. Both Indian and international experts in respective fields have provided the details that have been further scrutinized for exposition and usefulness to pediatric postgraduates by a chosen team of eminent academicians. We have liberally included tables, line diagrams, images, clinical photographs, illustrative figures, flow charts and algorithms in the main text. The book is divided into 10 major Parts and further arranged into 51 Sections and Annexures to cover all aspects of postgraduate pediatric curriculum. Themes which have major public health relevance for India are extensively covered. It is almost impossible to cover all pediatric problems with the same degree of detail, and hence a careful balance has been made in the details of description of diseases and their management to the needs of the students, and to keep the book to a manageable size. Summary points “In A Nutshell” are provided at the end of each chapter. Selected recent references—mostly leading articles, reviews and position statements—are provided for more detailed information, if desired by the student or the teacher.

Some kind of overlap is unavoidable in a book of this magnitude, with 725 plus minds working on more than 600 chapters simultaneously. We have strived hard to minimize it. We have also tried our best to keep all the chapters on an even keel despite the unavoidable diversity of disciplines, thoughts, experience, and expressive capabilities of the distinguished authors and section editors, from all over the globe. The book would not have been possible but for the support that we received from these erudite contributors. We are indebted to them for their knowledge, introspection, and judgment during the entire process. Together we have worked hard to produce a compilation that will be helpful to those who desire to learn more about child health in India and thus provide better care for children.

**Piyush Gupta**

# Acknowledgments

---

## ACKNOWLEDGMENTS FROM AUTHORS

### 2.1 Gene, Genome and Genetic Basis of Diseases

I have written similar chapters on basics of genetics and molecular medicine for three editions (8th, 9th and 10th) of the *API Textbook of Medicine* published by the Association of Physicians of India, Mumbai. I am grateful to Ms Smrithi for drawing the figures in this chapter.  
*Girisha KM*

### 3.1.1 Inborn Errors of Metabolism

We are grateful to our patients, their families, students, residents and colleagues for their help. We thank Dr Charushree Prasad for critically reviewing the chapter and providing suggestions.

*Chitra Prasad, CA Rupar*

### 9.1 Poisoning

I wish to acknowledge the help and support given to me by Dr Paul Nixon.

*P Ramesh Menon*

### 12.2 Assessment of the Newborn

We acknowledge the efforts of Dr Aliza Mittal in taking clinical photographs for the chapter.

*Harish Chellani, Sugandha Arya*

### 18.5 CNS Malformations

We gratefully acknowledge the help of Professors Sandeep Agarwal and M Srinivas by contributing the photographs for this chapter.

*Nidhi Sugandhi, Veereshwar Bhatnagar*

### 23.1 Basic Concepts of Vaccination

I have immensely benefitted from the interactions with many eminent vaccine experts, epidemiologists, academicians and public health program managers. A few of the concepts presented in this chapter could have been (knowingly and unknowingly) borrowed, developed and influenced by my interactions with national and international experts in these areas. I would like to acknowledge their teaching and influence. The opinions expressed in the chapter are solely of mine and should not be attributed to any institution/organization; I have been affiliated in the past or at present.

*Chandrakant Lahariya*

### 23.5 Adverse Events Following Immunization

I have borrowed heavily from my earlier publication (Vashishtha VM, Kalra A. Adverse Events following Immunization (AEFI), Vaccine Safety and Misinformation against Vaccination. Mumbai: Tree Life Media; 2014.) after due permission from the authors.

*Ajay Kalra*

### 23.13 Typhoid Fever Vaccines

We would like to thank Dr Leon Ochiai for the continuous guidance and encouragement and Dr Vittal Mogasale for constructive suggestions during the review process.

*Sushant Sahastrabuddhe, Mohammad Imran Khan*

### 31.19 HIV and Acquired Immunodeficiency Syndrome

We thank Dr Shubhangi Parkar, Dean (Incharge) of Seth GS Medical College and KEM Hospital, for granting permission to publish this manuscript.

*Milind S Tullu, Chhaya Divecha*

### 37.1 Applied Anatomy and Physiology of Liver and Biliary Tract

Special thanks to Dr Vijayshri Bhide, GI and Liver Pathologist, Department of Pathology, Deenanath Mangeshkar Hospital, Pune for sharing liver histology pictures.

*Vishnu Biradar*

### 40.39 Surgical Considerations in Congenital Heart Diseases

Acknowledgement and thanks to my teachers for their contribution and help me in gaining appropriate knowledge and skills to choose, offer and perform the correct operative procedure to scores of unfortunate children born with simple and complex congenital heart defects.

*R Benedict Raj*

#### 40.40 Preventive Cardiology in the Young

This publication was made possible by grant number 1 D43 HD065249 from the Fogarty International Center and the Eunice Kennedy Shriver National Institute of Child Health and Human Development at the National Institutes of Health.

*S Sivasankaran*

#### 42.11 Status Epilepticus

We wish to acknowledge the help and support provided by Lisa Garrity, Pharm D.

*Ravindra Arya, Katrina Peariso*

#### 42.24 Childhood Ataxia

I wish to acknowledge that a significant part of the discussion on genetic and inherited metabolic disorders associated with ataxia was included in a prior work on the same subject published for e-medicine. The material has been modified considerably to fit into a pertinent discussion on childhood ataxia. I also wish to acknowledge and thank contributors to the prior work; Professor Cheryl Greenberg (MD FRCPC), Division of Genetics and Metabolism, University of Manitoba; Dr Chitra Prasad (MD FRCPC FCCMG), Genetics and Metabolic Disorders, Program of South-Western Ontario; Professor M Jog (MD FRCPC), Division of Clinical Neurosciences, University of Western Ontario.

*Asuri N Prasad*

#### 47.1 Common Visual Problems

I wish to acknowledge the contribution of Dr Ankush Mutreja in preparation of Flow charts 1 to 5 included in this chapter.

*Kirti Singh*

#### 48.11 Cutaneous Manifestations of Collagen Vascular Diseases

I acknowledge Dr Ipsa Niyant Pandya, postgraduate student, Department of Skin and Veneral Diseases, Baroda Medical College, Vadodara, Gujarat for her invaluable contribution.

*Yogesh S Marfatia*

### FROM THE EDITORIAL DESK

**Ms Anju Kumari:** Secretarial assistance.

**Dr Sakshi Sachdeva:** Editorial assistance.

We would like to extend our thanks and appreciation to Shri Jitendar P Vij (Group Chairman) and Mr Ankit Vij (Group President) for their vision and belief in this project; Mr Tarun Duneja (Director-Publishing), Mr KK Raman (Production Manager), Ms Samina Khan (Exec. Assistant to Director-Publishing), Mr Sunil Kumar Dogra (Production Executive) and Mr Neelambar Pant (Production Coordinator), for their unflinching support and tireless work. We would also like to thank the entire staff of M/s Jaypee Brothers Medical Publishers (P) Ltd, New Delhi, India, especially Ms Shalu Mann (Medical Editor); Mr Gurnam Singh (Sr Proofreader); Mr Sarvesh Kumar, Ms Kamlesh Rawat, Mr Gyanendra Kumar (Proofreaders); Mr Rajesh Kumar, Mrs Yashu Kapoor, Mr Rakesh Kumar (Typesetters); Mr Satender Singh, Mr Sumit Kumar, Mr Rohan Prasad (Graphic Designers); and Mr Joginder Kumar for delivery of the proofs.

# Contents

## Volume 1: General Pediatrics and Neonatology

### PART I: Pediatrics—Yesterday, Today, Tomorrow

#### Section 1: INTRODUCTION TO PEDIATRICS

**Section Editors** Piyush Gupta, PSN Menon

1.1	Evolution of Pediatrics	1
	<i>KN Agarwal</i>	
1.2	20 Milestones in the History of Pediatrics	5
	<i>Santosh K Bhargava</i>	
1.3	Status of Child Health	8
	<i>RN Srivastava</i>	
1.4	Millennium Development Goals for Child Health	11
	<i>Raju C Shah, Pratima Shah, Kunal Ahya</i>	
1.5	Evidence-based Care in Pediatrics	16
	<i>Joseph L Mathew</i>	

### PART II: Basic Sciences as Applied to Pediatrics

#### Section 2: GENETICS AND GENETIC DISORDERS

**Section Editor** Shubha R Phadke

2.1	Gene, Genome and Genetic Basis of Diseases	20
	<i>Girisha KM</i>	
2.2	Patterns of Inheritance	26
	<i>Prajnya Ranganath, Shubha R Phadke</i>	
2.3	Clinical Dysmorphology: An Approach to Bedside Diagnosis	33
	<i>Ratna Dua Puri</i>	
2.4	Chromosomal Disorders	39
	<i>Shagun Aggarwal, Ashwin Dalal</i>	
2.5	Management of Genetic Disorders and Genetic Counseling	49
	<i>Shubha R Phadke</i>	
2.6	Prevention of Genetic Disorders	56
	<i>Neerja Gupta, Madhulika Kabra</i>	

#### Section 3: METABOLIC DISORDERS

**Section Editors** Madhulika Kabra, Neerja Gupta

3.1	Approach to Inborn Errors of Metabolism	61
	<i>Chitra Prasad, CA Rupar</i>	
3.2	Defects of Amino Acid Metabolism	70
	<i>Anil B Jalan, Ketki V Kudalkar</i>	

3.3	Urea Cycle Disorders	79
	<i>Sunita Bijarnia-Mahay</i>	
3.4	Organic Acidemias	86
	<i>Neerja Gupta</i>	
3.5	Fatty Acid Oxidation Defects	93
	<i>Manisha Goyal, Seema Kapoor</i>	
3.6	Mitochondrial Disorders	98
	<i>Sheffali Gulati, Biswaroop Chakrabarty</i>	
3.7	Peroxisomal Disorders	103
	<i>Madhulika Kabra, Neerja Gupta</i>	
3.8	Lysosomal Storage Disorders	106
	<i>IC Verma</i>	
3.9	GM1 and GM2 Gangliosidosis	114
	<i>Parag M Tamhankar</i>	
3.10	Gaucher Disease	117
	<i>Mamta Muranjan</i>	
3.11	Niemann-Pick Disease	127
	<i>Ashwin Dalal</i>	
3.12	Fabry Disease	131
	<i>Ratna Dua Puri</i>	
3.13	Defects of Carbohydrate Metabolism	135
	<i>Kausik Mandal</i>	
3.14	Glycogen Storage Diseases	141
	<i>Priya S Kishnani, Stephanie Austin</i>	
3.15	Pompe Disease	145
	<i>Mari Mori, Priya S Kishnani</i>	
3.16	Mucopolysaccharidoses	149
	<i>Girisha KM</i>	
3.17	Approach to Hypoglycemia	154
	<i>Meenakshi Bothra, Vandana Jain</i>	
3.18	Porphyrias	161
	<i>Meenal Agarwal, Shubha R Phadke</i>	
3.19	Newborn Screening	165
	<i>Seema Kapoor, Madhulika Kabra</i>	

#### Section 4: IMMUNITY, IMMUNE DISORDERS AND ALLERGY

**Section Editors** Surjit Singh, Amit Rawat

4.1	Basics of Immunology	169
	<i>Amit Rawat, Biman Saikia</i>	

4.2	Laboratory Diagnosis of Immune-mediated Diseases <i>Biman Saikia, Deepti Suri</i>	176	7.4	Pediatric Advanced Life Support (PALS) <i>Banani Poddar</i>	253
4.3	Primary Immunodeficiency Disorders <i>Manisha Madkaikar</i>	184	<b>Section 8: INTENSIVE CARE</b>		
4.4	Therapy for Primary Immunodeficiency Disorders <i>Revathi Raj, Surjit Singh</i>	191	<b>Section Editor</b> Rakesh Lodha		
4.5	Intravenous Immunoglobulin <i>Sujoy Khan, Surjit Singh</i>	193	8.1	Pediatric Intensive Care Unit <i>Dhiren Gupta, Neeraj Gupta, Manpreet Sethi</i>	264
4.6	Approach to a Child with Allergic Disorder <i>H Paramesh</i>	198	8.2	Shock <i>Srinivas Murthy, Niranjan Kissoon</i>	268
<b>Section 5: FLUID AND ELECTROLYTES</b>			8.3	Acute Respiratory Distress Syndrome <i>Venkat Shankar</i>	274
<b>Section Editor</b> Rakesh Lodha			8.4	Respiratory Failure <i>Lokesh Guglani</i>	281
5.1	Body Fluids <i>Raghuvamsi Chaitra, Suchitra Ranjit</i>	201	8.5	Mechanical Ventilation <i>Dinesh Raj, Rakesh Lodha</i>	288
5.2	Maintenance Fluid Therapy <i>Banani Poddar, Kirti M Naranje</i>	206	8.6	Sedation and Analgesia <i>Venkat Shankar</i>	297
5.3	Acid-Base Equilibrium <i>Dinesh Raj, Rakesh Lodha</i>	210	<b>Section 9: POISONING AND ENVENOMATION</b>		
5.4	Abnormalities of Acid-Base Balance <i>Dinesh Raj, Rakesh Lodha</i>	214	<b>Section Editor</b> Rakesh Lodha		
5.5	Sodium and Related Disorders <i>Andrew C Argent, Mignon I McCulloch</i>	220	9.1	Clinical Approach to a Poisoned Child <i>P Ramesh Menon</i>	302
5.6	Potassium <i>Virendra Kumar</i>	225	9.2	Poisonings by Common Drugs <i>Indumathy Santhanam, Sharada Sathish</i>	308
5.7	Magnesium Balance <i>Virendra Kumar</i>	229	9.3	Hydrocarbon Poisoning <i>Jayashree M, Karthi N</i>	315
<b>Section 6: DRUGS AND THERAPEUTICS</b>			9.4	Poisoning in the Household <i>Narayanan P, Harikrishnan KN</i>	318
<b>Section Editor</b> Sandeep B Bavdekar			9.5	Corrosive Poisoning <i>Urmila Jhamb</i>	326
6.1	Principles of Drug Therapy <i>Sandeep B Bavdekar</i>	231	9.6	Snakebite <i>S Mahadevan, R Ramesh Kumar</i>	331
6.2	Administration of Medications <i>Jeeson C Unni</i>	236	9.7	Scorpion Sting <i>S Mahadevan, R Ramesh Kumar</i>	341
<b>PART III: Intensive Care and Emergencies</b>			<b>Section 10: CHILDHOOD INJURIES</b>		
<b>Section 7: ACUTELY ILL CHILD AND RESUSCITATION</b>			<b>Section Editor</b> Rakesh Lodha		
<b>Section Editor</b> Rakesh Lodha			10.1	Trauma: Stabilization, Triage and Transport <i>Shruti Kant, Manu Madhok</i>	348
7.1	Assessment and Triage <i>Jayashree M, Sunit Singh</i>	241	10.2	Drowning/Submersion Injuries <i>Arun Bansal</i>	354
7.2	Cardiopulmonary Resuscitation <i>Utpal Bhalala, Vijay Srinivasan</i>	245	10.3	Animal Related Injuries <i>Arun Kumar Baranwal</i>	357
7.3	Basic Life Support (BLS) <i>Shalu Gupta</i>	249	10.4	Pediatric Burns <i>K Mathangi Ramakrishnan, V Jayaraman, T Mathivanan, V Srinivasan</i>	361
			10.5	Cold Injuries <i>Manu Madhok, Shruti Kant</i>	370

## PART IV: The Newborn Infant

### Section 11: NEONATAL PHYSIOLOGY AND ORGANIZATION OF CARE

**Section Editor** Siddarth Ramji

11.1	Fetal Physiology and Growth	376
	<i>Deepak Chawla</i>	
11.2	Maternal Influence on the Fetus	380
	<i>Jayashree Mondkar, Swati Manerkar</i>	
11.3	Transition of the Fetus to Newborn	383
	<i>Siddarth Ramji</i>	
11.4	Neonatal Mortality and Morbidities: An Overview	386
	<i>Aparna Chandrasekaran, M Jeeva Sankar</i>	
11.5	Organization of Neonatal Care	392
	<i>Subhash Chandra Shaw, Vinod K Paul</i>	

### Section 12: NORMAL NEWBORN

**Section Editor** Siddarth Ramji

12.1	Delivery Room Care of the Newborn	396
	<i>Siddarth Ramji</i>	
12.2	Assessment of the Newborn	401
	<i>Harish Chellani, Sugandha Arya</i>	
12.3	Care of the Normal Newborn	408
	<i>Somashekhar Nimbalkar</i>	
12.4	Maintenance of Temperature	412
	<i>Suksham Jain, Ravish Singhal</i>	
12.5	Breastfeeding and Lactation Management	417
	<i>NB Mathur</i>	

### Section 13: DISORDERS OF WEIGHT AND GESTATION

**Section Editor** Siddarth Ramji

13.1	Low Birthweight: Classification and Etiology	422
	<i>Ruchi Nimish Nanavati</i>	
13.2	Prematurity and Intrauterine Growth Restriction	427
	<i>Ashok Kumar, Sriparna Basu</i>	
13.3	Feeding of Low Birthweight	432
	<i>Kanya Mukhopadhyay</i>	
13.4	Long-term Outcome of Low Birthweight	437
	<i>Suman Rao PN, Nikhil Kulkarni</i>	
13.5	Postmaturity	442
	<i>Reeta Bora, Pranay Phukan</i>	
13.6	Large for Gestational Age	445
	<i>Rhishikesh Thakre</i>	
13.7	Multiple Gestations	449
	<i>Mamta Jajoo</i>	

### Section 14: HIGH-RISK NEWBORN

**Section Editor** Siddarth Ramji

14.1	Recognition of High-Risk Neonate	453
	<i>Niranjan Thomas, Vijay Gupta</i>	
14.2	Birth Injuries	462
	<i>Neeraj Gupta</i>	
14.3	Jaundice in the Newborn	469
	<i>Sheila S Mathai, Kannan Venkatnarayan</i>	
14.4	Infant of Diabetic Mother	479
	<i>Srinivas Murki, Tejo Oleti Pratap</i>	
14.5	Neonatal Hypoglycemia	483
	<i>Shiv Sajjan Saini, Praveen Kumar</i>	
14.6	Anemia and Polycythemia	489
	<i>Venkataseshan Sundaram, Bikramjit Das</i>	
14.7	The Bleeding Neonate	498
	<i>Arun Kumar</i>	
14.8	Hemorrhagic Disease of the Newborn	503
	<i>JN Sharma</i>	
14.9	Thrombocytopenia in the Newborn	506
	<i>Pradeep Sharma</i>	
14.10	Cyanosis in the Newborn	508
	<i>K Anil Kuruvilla, Vijay Gupta</i>	
14.11	Necrotizing Enterocolitis	515
	<i>Krishna Kumar Diwakar</i>	
14.12	Retinopathy of Prematurity	521
	<i>Ashish Jain, Veeraraja B Sathenahalli, Karobi Lahiri Coutinho</i>	
14.13	Neonatal Transport	527
	<i>Neelam Kler, Anup Thakur</i>	
14.14	Follow-Up of the High-Risk Neonate	532
	<i>Shuchita Gupta</i>	

### Section 15: NEONATAL INFECTIONS

**Section Editor** Siddarth Ramji

15.1	Neonatal Sepsis	540
	<i>Suman Chaurasia, Ramesh Agarwal</i>	
15.2	Superficial Infections	547
	<i>Sriparna Basu, Ashok Kumar</i>	
15.3	Meningitis in the Newborn	552
	<i>Kumutha Jayaraman, Manigandan Chandrasekaran</i>	
15.4	Deep-seated Infections	559
	<i>Kumutha Jayaraman, Manigandan Chandrasekaran</i>	
15.5	Neonatal Tetanus	563
	<i>Mala Kumar, Shalini Tripathi</i>	
15.6	Intrauterine Infections	565
	<i>Sriparna Basu, Ashok Kumar</i>	

## Section 16: NEUROLOGICAL PROBLEMS OF THE NEWBORN INFANT

**Section Editor** Siddarth Ramji

16.1	Seizures in the Neonates	572
	<i>Amit Upadhyay, Pranjali Saxena</i>	
16.2	Hypoxic Ischemic Encephalopathy	578
	<i>B Vishnu Bhat, B Adhisivam</i>	
16.3	Intraventricular Hemorrhage and White Matter Injury	585
	<i>Shamik Trivedi, Amit M Mathur</i>	

## Section 17: RESPIRATORY PROBLEMS OF THE NEWBORN INFANT

**Section Editor** Siddarth Ramji

17.1	Approach to a Neonate with Respiratory Distress	592
	<i>Swarna Rekha Bhat</i>	
17.2	Neonatal Apnea	596
	<i>Manoj Modi</i>	
17.3	Neonatal Ventilation	600
	<i>Sourabh Dutta</i>	
17.4	Hyaline Membrane Disease	605
	<i>Praveen Kumar, Anuj Bhatti</i>	
17.5	Transient Tachypnea of the Newborn	612
	<i>Srinivas Murki</i>	
17.6	Meconium Aspiration Syndrome	614
	<i>Naveen Jain</i>	
17.7	Pulmonary Air Leaks in the Newborn	617
	<i>Manish Balde, Sanjay Wazir</i>	
17.8	Persistent Pulmonary Hypertension (PPHN)	622
	<i>Neeraj Gupta</i>	
17.9	Pulmonary Hemorrhage	629
	<i>Emily F Fishman, Rakesh Rao</i>	
17.10	Bronchopulmonary Dysplasia in Newborn	635
	<i>Samir Gupta, Sunil K Sinha</i>	

## Section 18: NEONATAL MALFORMATIONS

**Section Editor** Siddarth Ramji

18.1	Esophageal Atresia and Tracheoesophageal Fistula	640
	<i>Yogesh Kumar Sarin, Shalini Sinha</i>	
18.2	Diaphragmatic Hernia and Eventration	645
	<i>Shalini Sinha, Yogesh Kumar Sarin</i>	
18.3	Gastrointestinal and Abdominal Malformations	650
	<i>Satish Kumar Aggarwal</i>	
18.4	Genitourinary Malformations	661
	<i>Satish Kumar Aggarwal</i>	
18.5	CNS Malformations	670
	<i>Nidhi Sugandhi, Veereshwar Bhatnagar</i>	

## PART V: The Childhood Years

### Section 19: GROWTH: NORMAL AND ABNORMAL

**Section Editor** Anju Seth

19.1	Normal Growth	680
	<i>Ruchi Mishra, Vandana Jain</i>	
19.2	Factors Affecting Growth	684
	<i>Devi Dayal, Anil Kumar Bhalla</i>	
19.3	Assessment of Physical Growth	688
	<i>Anju Seth, Rajni Sharma</i>	
19.4	Dental Development and Anomalies	713
	<i>Sunanda Roychoudhury, Shakil Ahmed Nagori, Ajoy Roychoudhury</i>	
19.5	Bone Age and Predicted Final Height	723
	<i>M Vijayakumar, Anju Seth</i>	
19.6	Failure to Thrive	726
	<i>Sudha Rao Chandrashekhar</i>	
19.7	Overweight and Obesity	733
	<i>Rajesh Khadgawat, Aashima Dabas</i>	
19.8	Abnormalities of Stature	739
	<i>Senthil Senniappan, Leena Patel</i>	

### Section 20: DEVELOPMENT AND DEVELOPMENTAL DELAY

**Section Editors** Anand Pandit, Sudha Chaudhari

20.1	Introduction to Development, Laws of Development, and Factors Affecting Development	749
	<i>Satnam Kaur</i>	
20.2	Normal Development	753
	<i>Ujjwal Nene</i>	
20.3	Approach to Diagnosis of Developmental Delay: Developmental Screening and Surveillance	759
	<i>Sudha Chaudhari</i>	
20.4	Global Developmental Delay	766
	<i>Madhuri Kulkarni, Mona P Gajre</i>	
20.5	Intellectual Disability	770
	<i>Suja Koshy</i>	
20.6	Visual Impairment	780
	<i>Nikhil Rishikeshi, Sucheta Kulkarni</i>	
20.7	Hearing Impairment	782
	<i>Neelam Vaid</i>	
20.8	Cerebral Palsy	787
	<i>Sharmila Banerjee Mukherjee</i>	

## Section 21: BEHAVIOR AND LEARNING

**Section Editors** Monica Juneja, Devendra Mishra

21.1	Moral Development	800
	<i>Prahbjot Malhi, Rajalakshmi Iyer</i>	
21.2	Sleep Hygiene and Disorders of Sleep	803
	<i>Suresh Kotagal</i>	
21.3	Common Behavioral Problems	809
	<i>Praveen Suman</i>	
21.4	Enuresis and Encopresis	813
	<i>Piyush Gupta, Ruchi Mishra</i>	
21.5	Breath-Holding Spells	818
	<i>Sumaira Khalil, Devendra Mishra</i>	
21.6	Common Speech, Language and Communication Disorders	821
	<i>Prathibha Karanth</i>	
21.7	Autism Spectrum Disorder	827
	<i>Monica Juneja, Rahul Jain</i>	
21.8	Rett Syndrome	833
	<i>Monica Juneja, Rajni Khajuria</i>	
21.9	Attention Deficit Hyperactivity Disorder	836
	<i>Rajesh Sagar, Rohit Verma</i>	
21.10	Oppositional Defiant and Conduct Disorders	843
	<i>Rajesh Sagar, Rajevee Ranjan</i>	
21.11	Learning Disabilities	847
	<i>Nandini Mundkur, Chitra Sankar</i>	
21.12	Anorexia Nervosa and Bulimia	851
	<i>Koushik Sinha Deb, Rajesh Sagar</i>	
21.13	Anxiety Disorders	854
	<i>Shoba Srinath, Preeti Kandasamy</i>	
21.14	Evaluation of Mental Well-Being	856
	<i>Manju Mehta, Sneha Kapoor</i>	
21.15	Management of Psychological Illness	858
	<i>Paul Russell</i>	

## Section 22: NUTRITION AND NUTRITIONAL DISORDERS

**Section Editors** KE Elizabeth, Piyush Gupta

22.1	Nutrient Groups and Nutritional Requirements	863
	<i>KE Elizabeth, S Bindusha</i>	
22.2	Nutritive Values of Foods	868
	<i>Neetu Sharma, Piyush Gupta</i>	
22.3	Infant and Young Child Feeding	877
	<i>JP Dadhich</i>	
22.4	Feeding During Childhood and Food Allergy	881
	<i>KE Elizabeth, S Bindusha</i>	
22.5	Undernutrition: Prevalence and Etiology	884
	<i>Piyush Gupta, Neetu Sharma</i>	

22.6	Pathophysiology of Undernutrition	891
	<i>OP Mishra</i>	
22.7	Protein Energy Malnutrition	894
	<i>KE Elizabeth</i>	
22.8	Severe Acute Malnutrition	899
	<i>Praveen Kumar, Preeti Singh</i>	
22.9	Vitamin A	907
	<i>Neetu Sharma, Piyush Gupta</i>	
22.10	Vitamin B Complex Deficiency	913
	<i>Vineeta Gupta</i>	
22.11	Vitamin C and Scurvy	917
	<i>Tejinder Singh, Shaveta Kundra</i>	
22.12	Vitamin D, Nutritional Rickets and Hypervitaminosis D	920
	<i>S Balasubramanian</i>	
22.13	Iodine Deficiency Disorders	925
	<i>Umesh Kapil, Neha Sareen</i>	
22.14	Zinc in Child Health	928
	<i>Shashi Ajit Chiplonkar</i>	
22.15	Trace Elements in Nutrition and Health	932
	<i>P Leelakumari, KE Elizabeth</i>	
22.16	Fluorosis	935
	<i>Sunil Kumar Gupta</i>	
22.17	Enteral and Parenteral Nutrition	941
	<i>Ashish Bavdekar</i>	
22.18	Nutrition in the 21st Century	946
	<i>Gouri Rao Passi, Piyush Gupta</i>	
22.19	National Nutrition Programs	950

## Section 23: IMMUNIZATION

**Section Editors** Vipin M Vashishtha, Ajay Kalra

23.1	Basic Concepts of Vaccination	953
	<i>Chandrakant Lahariya</i>	
23.2	Vaccine Administration Practices	962
	<i>Satish V Pandya</i>	
23.3	Scheduling of Vaccines	966
	<i>Vipin M Vashishtha</i>	
23.4	Vaccine Storage and Cold Chain	972
	<i>Karan Singh Sagar, Manish Jain</i>	
23.5	Adverse Events Following Immunization	978
	<i>Ajay Kalra</i>	
23.6	BCG Vaccine	982
	<i>Sangeeta Sharma</i>	
23.7	Poliovirus Vaccines	986
	<i>Puneet Kumar, Vipin M Vashishtha</i>	
23.8	Diphtheria, Tetanus and Pertussis Vaccines	991
	<i>Puneet Kumar, Vipin M Vashishtha</i>	

23.9	Hepatitis B Vaccine <i>Ajay Kalra</i>	995
23.10	<i>Haemophilus Influenzae</i> Type B (HIB) Vaccines <i>AK Patwari</i>	998
23.11	Measles Vaccine <i>Sumit Mehndiratta, AP Dubey</i>	1000
23.12	Rubella and Mumps Vaccines <i>Aashima Dabas, Piyush Gupta</i>	1002
23.13	Typhoid Fever Vaccines <i>Sushant Sahastrabudhe, Mohammad Imran Khan</i>	1005
23.14	Japanese Encephalitis Vaccine <i>VG Ramachandran</i>	1009
23.15	Rabies Vaccines <i>Anuradha Bose</i>	1011
23.16	Pneumococcal Vaccines <i>Puneet Kumar, Vipin M Vashishtha</i>	1014
23.17	Rotavirus Vaccines <i>Gagandeep Kang</i>	1018
23.18	Cholera Vaccines <i>Monjori Mitra</i>	1020
23.19	Varicella Vaccine <i>Rakesh Kumar</i>	1022
23.20	Hepatitis A Vaccine <i>Vikram Gagneja, AJ Chitkara</i>	1024
23.21	Meningococcal Vaccine <i>Jaydeep Choudhury</i>	1027
23.22	Seasonal and Pandemic Influenza Vaccines <i>Shobha Broor</i>	1029
23.23	Human Papillomavirus Vaccines <i>Srinivas G Kasi</i>	1034
23.24	Yellow Fever Vaccine <i>Parang N Mehta</i>	1038
23.25	Combination Vaccines <i>Niranjan Shendurnikar, Sheila Aiyer</i>	1040
23.26	Immunization in Special Situations <i>Panna Choudhury</i>	1043

## PART VI: The Adolescent

### Section 24: ADOLESCENT DEVELOPMENT

**Section Editor** MKC Nair

24.1	Adolescence and Adolescent <i>MKC Nair, Paul Russell</i>	1047
24.2	Sexual Development and Sexuality <i>Chandrika Rao</i>	1051
24.3	Psychosocial Development <i>Yamuna S</i>	1055

### Section 25: HEALTH ISSUES IN ADOLESCENCE

**Section Editor** MKC Nair

25.1	Factors Influencing Adolescent Health <i>Sukanta Chatterjee</i>	1061
25.2	Adolescent Nutrition <i>Preeti M Galagali</i>	1067
25.3	Mental Health <i>Priya Mary Mammen</i>	1074
25.4	Injuries, Violence and Suicide <i>Srikanta Basu</i>	1080
25.5	Menstrual Disorders and Polycystic Ovary Syndrome <i>Amita Suneja, Richa Aggarwal</i>	1087
25.6	Sexually Transmitted Infections <i>Newton Luiz</i>	1095
25.7	Teenage Pregnancy <i>Amita Suneja, Richa Aggarwal</i>	1100

### Section 26: CARE OF ADOLESCENTS

**Section Editor** MKC Nair

26.1	Promoting Health of Adolescents <i>Harish K Pemde, Kamlesh Harish</i>	1102
26.2	Adolescent Counseling <i>Atul M Kanikar</i>	1107
26.3	Adolescent Friendly Health Services <i>Rajesh Mehta, Neena Raina, Patanjali Dev Nayar</i>	1115

## Volume 2: Infections and Systemic Disorders

### PART VII: Infectious Diseases

#### Section 27: BASIC CONCEPTS

**Section Editors** Jaydeep Choudhury, Piyush Gupta

27.1	Epidemiology of Infectious Diseases <i>VG Ramachandran, Piyush Gupta</i>	1119	27.2	Laboratory Diagnosis of Infection <i>Sankar Sengupta</i>	1125
			27.3	Antimicrobial Resistance <i>Anuradha De</i>	1129
			27.4	Infection Control and Prevention <i>Jaydeep Choudhury</i>	1136

## Section 28: FEVER

**Section Editor** Piyush Gupta

28.1	Approach to a Child with Fever <i>Bhavna Dhingra, Piyush Gupta</i>	1140
28.2	Fever: General Principles of Management <i>Piyush Gupta, Bhavna Dhingra</i>	1143
28.3	Fever without Focus <i>Piyush Gupta, Bhavna Dhingra</i>	1146
28.4	Fever of Unknown Origin <i>Bhavna Dhingra, Piyush Gupta</i>	1149

## Section 29: BACTERIAL INFECTIONS

**Section Editors** Jaydeep Choudhury, Piyush Gupta

29.1	Natural History of Bacterial Infection <i>VG Ramachandran, Piyush Gupta</i>	1152
29.2	Principles of Antibiotic Therapy <i>Anita Shet</i>	1155
29.3	Diphtheria <i>Prerna Batra, Piyush Gupta</i>	1162
29.4	Pertussis <i>Piyush Gupta, Prerna Batra</i>	1166
29.5	Tetanus <i>Jaydeep Choudhury</i>	1169
29.6	Typhoid Fever <i>Apurba Ghosh, Monjori Mitra</i>	1171
29.7	Nontyphoidal Salmonellosis <i>Thangavelu Sangaralingam, Janani Ravi</i>	1176
29.8	<i>Haemophilus influenzae</i> B Infections <i>Somu Sivabalan</i>	1179
29.9	Pneumococcal Infections <i>Meenu Singh, Nishant Jaiswal</i>	1182
29.10	Streptococcal Infections <i>Pramod Sharma</i>	1185
29.11	Staphylococcal Infections <i>Zaki Syed</i>	1188
29.12	<i>Neisseria</i> Infections <i>Vidushi Mahajan</i>	1193
29.13	<i>Pseudomonas</i> Infections <i>Nupur Ganguly</i>	1196
29.14	Leptospirosis <i>Janani Sankar</i>	1198
29.15	Plague <i>Baldev S Prajapati, Rajal B Prajapati, Piyush Gupta</i>	1201
29.16	Brucellosis <i>Sriram Krishnamurthy</i>	1204

29.17	Relapsing Fever <i>P Ramachandran</i>	1207
29.18	Lyme Disease <i>P Ramachandran</i>	1210
29.19	Nocardiosis <i>Subhasish Bhattacharyya</i>	1212
29.20	Actinomycosis <i>Subhasish Bhattacharyya</i>	1214
29.21	<i>Helicobacter pylori</i> <i>John Matthai, Sarah Paul</i>	1215
29.22	Anaerobic Infections <i>Rekha Harish, Anuj Bhatti</i>	1217

## Section 30: MYCOBACTERIAL INFECTIONS

**Section Editor** Soumya Swaminathan

30.1	Antitubercular Drugs <i>Geetha Ramachandran</i>	1220
30.2	Tuberculosis <i>Soumya Swaminathan, N Pooranagangadevi, Ben J Marais</i>	1225
30.3	Atypical Mycobacterial Infections <i>C Padmapriyadarsini, Soumya Swaminathan</i>	1235
30.4	Leprosy <i>Rajeshwar Dayal, Manoj Kumar Singh</i>	1239

## Section 31: VIRAL DISEASES

**Section Editors** Ashok Kumar Dutta, Piyush Gupta

31.1	Epidemiology of Viral Infections <i>VG Ramachandran, Piyush Gupta</i>	1243
31.2	Poliomyelitis <i>Ashok Kumar Dutta</i>	1245
31.3	Measles <i>Shilpa Khanna Arora, Piyush Gupta</i>	1248
31.4	Mumps <i>Shilpa Khanna Arora, Piyush Gupta</i>	1252
31.5	Rubella <i>Pooja Dewan, Piyush Gupta</i>	1255
31.6	Varicella <i>Piyush Gupta, Aashima Dabas</i>	1259
31.7	Parvovirus Infections <i>Jagdish Chandra, Anu Maheshwari</i>	1263
31.8	Roseola Infections <i>Swati Singhal</i>	1268
31.9	Viral Hepatitis <i>Amit Goel, Chhavi Nanda</i>	1270
31.10	Rabies <i>Jaydeep Choudhury</i>	1275

31.11	Japanese Encephalitis <i>Rashmi Kumar, Piyush Tripathi</i>	1278	32.13	Filariasis <i>Ajay Gaur</i>	1368
31.12	Infectious Mononucleosis <i>Rashmi Ranjan Das</i>	1282	32.14	Intestinal, Liver and Lung Flukes <i>Vikas Jain</i>	1372
31.13	Enteroviral Infections <i>Annapurna Sudarsanam</i>	1287	32.15	Tapeworm Diseases <i>Ruchi Rai</i>	1376
31.14	Herpes Simplex Infections <i>Niranjan Mohanty, Pradeep S</i>	1292	32.16	Hydatid Disease: Echinococcosis <i>SK Gupta</i>	1380
31.15	Influenza <i>Sonal Kansra, Alison Scott</i>	1296	32.17	Schistosomiasis <i>Ritabrata Kundu, Devdeep Mukherjee</i>	1384
31.16	Dengue <i>Piyush Gupta, Aashima Dabas</i>	1299	<b>Section 33: FUNGAL INFECTIONS</b>		
31.17	Chikungunya Fever <i>Rajniti Prasad</i>	1307	<b>Section Editor</b> <i>Piyush Gupta</i>		
31.18	Viral Hemorrhagic Fevers <i>Nigam Prakash Narain, Priya Verma</i>	1310	33.1	Fungi <i>VG Ramachandran, Piyush Gupta</i>	1386
31.19	HIV and Acquired Immunodeficiency Syndrome <i>Milind S Tullu, Chhaya Divecha</i>	1313	33.2	Antifungal Therapy <i>Arunaloke Chakrabarti, Prashant Sood</i>	1387
<b>Section 32: PARASITIC INFECTIONS AND INFESTATIONS</b>			33.3	Candidiasis <i>Khaya Ghosh Uttam</i>	1392
<b>Section Editors</b> <i>Ritabrata Kundu, Piyush Gupta</i>			33.4	Aspergillosis <i>Kana Ram Jat</i>	1396
32.1	Epidemiology of Parasitic Infections <i>Piyush Gupta, VG Ramachandran</i>	1328	33.5	Cryptococcosis <i>Ankit Parakh</i>	1399
32.2	Malaria <i>Ritabrata Kundu</i>	1331	33.6	Coccidioidomycosis <i>James Homans, Yee Aye</i>	1402
32.3	Leishmaniasis <i>Shyam Sundar, Jaya Chakravarty</i>	1337	33.7	Blastomycosis <i>G Raghurama Rao</i>	1407
32.4	Amebiasis <i>Piyush Gupta, Aashima Dabas</i>	1343	33.8	Histoplasmosis <i>S Nivedhana, S Balasubramanian</i>	1409
32.5	Giardiasis <i>Aashima Dabas, Piyush Gupta</i>	1347	33.9	<i>Pneumocystis jirovecii</i> (previously classified as <i>P. carinii</i> ) <i>Ira Shah, Khushnuma Mullanfiroze</i>	1412
32.6	Cryptosporidiosis <i>Aashima Dabas, Piyush Gupta</i>	1350	<b>Section 34: RICKETTSIAL AND OTHER INFECTIONS</b>		
32.7	Ascariasis <i>Sutapa Ganguly</i>	1352	<b>Section Editors</b> <i>S Balasubramanian, Piyush Gupta</i>		
32.8	Hookworm Infestation <i>Maitreyi Basu, Sutapa Ganguly</i>	1355	34.1	Epidemiology, Classification, and Approach to Diagnosis of Rickettsial Infections <i>Narendra Rathi</i>	1415
32.9	Trichuriasis <i>Sutapa Ganguly</i>	1358	34.2	Spotted Fevers <i>Atul A Kulkarni</i>	1418
32.10	Enterobiasis <i>Dhrubojyoti Mridha, Sutapa Ganguly</i>	1360	34.3	Scrub Typhus <i>Veena R Parmar</i>	1422
32.11	Strongyloidiasis <i>Ravi Ambey, Tripty Naik</i>	1362	34.4	Epidemic Typhus <i>Sunil Vaidya, Atul A Kulkarni</i>	1424
32.12	Trichinosis <i>Akash Bang, Puja Hingorani</i>	1365	34.5	Murine Typhus (Endemic Typhus) <i>Govind Benakatti, LH Bidari</i>	1426

<b>34.6</b>	<i>Mycoplasma</i> Infections <i>Tanu Singhal</i>	1428	<b>35.19</b>	Abdominal Tuberculosis <i>Yogesh Waikar</i>	1496
<b>34.7</b>	Chlamydial Infections <i>Sulochana Putali Bai</i>	1430	<b>35.20</b>	Ascites <i>Malathi Sathiyasekeran, R Ganesh</i>	1498

## PART VIII: Systemic Disorders

### Section 35: GASTROINTESTINAL DISORDERS

**Section Editors** *A Riyaz, John Matthai*

<b>35.1</b>	Anatomy and Physiology <i>S Arivu Selvan</i>	1432	<b>35.23</b>	Appendicitis <i>Prakash Agarwal</i>	1506
<b>35.2</b>	Common Symptoms of Gastrointestinal Diseases <i>Sarah Paul, John Matthai</i>	1437	<b>35.24</b>	Testicular Torsion <i>Prakash Agarwal</i>	1508
<b>35.3</b>	Cleft Lip and Cleft Palate <i>VS Akbar Sherif, Sayed Mohammed Akbar</i>	1439	<b>35.25</b>	Inguinal Hernia <i>Prakash Agarwal</i>	1510
<b>35.4</b>	Dental Caries <i>Madhu S</i>	1442	<b>Section 36: DIARRHEAL ILLNESSES</b>		
<b>35.5</b>	Recurrent Parotitis <i>Prakash Agarwal</i>	1445	<b>Section Editor</b> <i>AK Patwari</i>		
<b>35.6</b>	Vomiting <i>Sumathi Bavanandam</i>	1447	<b>36.1</b>	Acute Watery Diarrhea <i>AK Patwari</i>	1511
<b>35.7</b>	Infantile Hypertrophic Pyloric Stenosis <i>Ketan Parikh</i>	1451	<b>36.2</b>	Dysentery <i>AKM Iqbal Kabir, Lazina Sharmin</i>	1519
<b>35.8</b>	Gastroesophageal Reflux <i>Elsie Jazmin Foglio, Dinesh S Pashankar</i>	1453	<b>36.3</b>	Cholera <i>Piyush Gupta, Rashi Singhal</i>	1523
<b>35.9</b>	Umbilical Hernia <i>Prakash Agarwal</i>	1457	<b>36.4</b>	Persistent Diarrhea <i>Shinjini Bhatnagar, Aashima Dabas, Dheeraj Shah</i>	1527
<b>35.10</b>	Constipation <i>Praveen Kumar, Preeti Singh</i>	1459	<b>36.5</b>	Chronic Diarrhea <i>BR Thapa, Srikanth KP, Babu Lal Meena</i>	1533
<b>35.11</b>	Hirschsprung Disease <i>Ketan Parikh</i>	1464	<b>36.6</b>	Antibiotic Associated Diarrhea <i>Seema Alam, Vikrant Sood</i>	1551
<b>35.12</b>	Chronic Abdominal Pain <i>B Bhaskar Raju, Sumathi Bavanandam</i>	1466	<b>Section 37: HEPATOBILIARY DISEASES</b>		
<b>35.13</b>	Acid Peptic Disease <i>R Bhanu Vikraman Pillai</i>	1470	<b>Section Editor</b> <i>Surender Kumar Yachha</i>		
<b>35.14</b>	Pancreatitis <i>A Riyaz, Geeta M Govindaraj</i>	1473	<b>37.1</b>	Applied Anatomy and Physiology of Liver and Biliary Tract <i>Vishnu Biradar</i>	1555
<b>35.15</b>	Practical Approach to Malabsorption <i>VS Sankaranarayanan</i>	1478	<b>37.2</b>	Liver Function Tests <i>Neelam Mohan, Sakshi Karkra</i>	1558
<b>35.16</b>	Specific Malabsorption Syndromes <i>Srinivas S</i>	1481	<b>37.3</b>	Neonatal Cholestasis <i>Surender Kumar Yachha, Moinak Sen Sarma</i>	1563
<b>35.17</b>	Inflammatory Bowel Disease <i>Rishi Bolia, Anshu Srivastava</i>	1484	<b>37.4</b>	Portal Hypertension <i>Surender Kumar Yachha, Moinak Sen Sarma</i>	1571
<b>35.18</b>	Celiac Disease <i>Lalit Bharadia</i>	1491	<b>37.5</b>	Gastrointestinal Bleeding <i>Nishant Wadhwa</i>	1586
			<b>37.6</b>	Liver Abscess <i>Upender Shava, Anshu Srivastava</i>	1593
			<b>37.7</b>	Acute Hepatitis <i>Barath Jagadisan</i>	1598

<b>37.8</b>	Chronic Liver Disease <i>Seema Alam, Rajeev Khanna</i>	1602	<b>38.18</b>	Other Clotting Factor Deficiencies <i>Sunil Gomber, Archana Kashyap</i>	1731

### LABORATORY VALUES AND DRUG DOSES

**Section Editor** Pooja Dewan

<b>Annexure A:</b>	Laboratory Reference Values <i>Nidhi Bedi, Pooja Dewan</i>	3041
<b>Annexure B:</b>	Drug Doses <i>Pooja Dewan, Nidhi Bedi</i>	3050

# PART I Pediatrics—Yesterday, Today, Tomorrow

## Section 1 INTRODUCTION TO PEDIATRICS

**Section Editors** Piyush Gupta, PSN Menon

### Chapter 1.1

### Evolution of Pediatrics

KN Agarwal

Pediatrics is the medical science for children, who are in a phase of active growth and progressive development. The word *pediatrics* and its cognates mean *healer of children*; derived from two Greek words: *pais* (child) and *iatros* (doctor or healer).

Newborns, toddlers, children and adolescents have physical and emotional needs and health concerns different from adults. They are growing at varying rates in different phases of life—somatic growth, growth and development of brain, lymphoid tissue enlargement, and sexual development; thus energy needs and body metabolism remain active. In contrast adults are in a static maintenance phase, thus their macro- and micro-nutrient needs are more or less regulated and unchanging. Pediatricians take care of all these needs from birth up to age 18. Present estimates are that brain growth completes around 25 years of age. The science of pediatrics has intimate relationship with mother from conception and birth, making obstetrics, gynecology and pediatrics almost inseparable. In addition it is hard to recognize diseases in young children with inherent difficulty in oral communication, and in whom eliciting clinical information is problematic.

### DISEASES OF CHILDREN AND THEIR MANAGEMENT IN ANCIENT TIMES

#### India

The “*Atharva Veda*” (1000 BC), a medical textbook explaining how to treat diseases, described *breastmilk* as nectar. “*Charaka Samhita*” (400–200 BC) and “*Kashyap Samhita*” (written by a pediatrician around 6th century BC to 2nd century AD) described importance of breastmilk and advised breastfeeding from the first day of birth. “*Sushruta Samhita*” (dealing with surgical procedures; 500 BC) stated breastmilk as beverage of immortality. Unfortunately it advised discarding of colostrum for the first three days and advocated feeding of honey and butter to facilitate discharge of meconium. Infant bath with lukewarm water and feeding of cereal and/or lentil (*annapraasan*) was recommended after 6 months of age.

Charaka knew that blood vessels brought food to various parts of the body and carried wastes away. He also made the earliest Indian reference to smallpox. Madhava (700 AD) practiced inoculation to keep people from catching smallpox, by scraping pus or scabs from the patient and administering as an inoculation, either by sticking it into the skin on a needle, or by blowing the powder up the nose.

#### Egypt

*Ebers Papyrus* (1550 BC) is a summary of the medical and surgical therapeutics practiced in ancient Egypt. In a tiny pediatric section which is mainly prognostic it reads as follows:

- To get a supply of milk in a woman's breast for suckling a child, warm the bones of swordfish in oil and rub her back with it.
- Prognosis for a child on the day its birth: if it cries nicely, it will live; if it cries badly, it will die. If it wails loudly, it will die; if it drops its face downwards, it will die immediately.

*Ebers Papyrus* also describes a few other topics including breastfeeding, a cure for worms, and treatment of eye diseases.

#### Islamic Empire

##### (Iraq, Iran, Israel, Lebanon and Syria)

Islamic physicians studied in depth all the medical observations and logic of Hippocrates, his followers and Galen, combined with the work of the Indian physicians Sushruta and Charaka, whose books were translated into Arabic around 750 AD. Their observations helped to develop useful cures for some diseases. Another achievement of these practitioners was that they started the world's first hospitals, where the contagious patients of smallpox and measles were isolated and treated.

Al Razi (870–900 AD), Persian physician wrote in a book the first description of how to differentiate measles and smallpox. However he did not mention inoculation though it was already being done in India. Ibn Sina, the great Arabian physician (known as Avicenna in Europe, 990 AD) discussed tetanus, worm infestations, convulsions, meningitis and umbilical abscess. He was the first to observe that tuberculosis and smallpox are contagious.

#### China

Pediatrics was one of the oldest specialties within Chinese medicine and dates from the early first millennium. This form of Asian medicine is the oldest and second largest medical system in the world today and is used by one quarter of the world's population. Children according to Chinese belief are weak and susceptible to diseases that affect the lungs (such as colds, coughs, allergies and asthma) and the spleen (or digestive complaints such as colic, vomiting, diarrhea, indigestion, and stomach aches). In traditional Chinese medicine, there are four primary methods of treating children—dietary therapy, Chinese herbal medicine, Chinese pediatric massage and acupuncture.

#### Greece

Around 300 BC and afterwards Greek physicians established a logical system for understanding disease. “*Hippocratic Writings*”, named after the first and most famous of these physicians, (460 BC) give descriptions for cephalhematoma, hydrocephalus, clubfoot, worm infestations, diarrhea, scrofula, asthma, and mumps. Significant advances were made in childbearing with the

introduction of the “*Hippocratic Corpus*” in the 3rd century BC, though this document advised the practice of many superstitions.

Galen (200 AD) suggested advancement in medicine for women, though he focused mostly on specific diseases with some aspects of labor. He also wrote of ear discharge, pneumonia, intestinal prolapse and possibly rickets.

Soranus of Ephesus (98–138 AD) wrote in the 2nd century on childbirth and obstetrics. For birth, the mother was made to sit on a birthing stool with a midwife in front of her and female aids standing at her sides. In a normal head-first delivery, the cervical opening was stretched slightly, and the rest of the body was pulled out. He instructed the midwife to wrap her hands in pieces of cloth or thin paper so that the slippery newborn did not slide out of her grasp. On the care of the newborn, his teachings as described in “*On Diseases of Women*” were followed to a large extent. He was the first to advise the salting and saddling of the newborn infant, a practice dating back to 600 BC. He also described a testing of the breastmilk by the behavior of a drop of milk placed on fingernail. This continued for over 1600 years.

Weakness at birth was attributed to prematurity, with heavy mortality. But Isaac Newton (1643–1727), Christopher Wren (1632–1723), and Jonathan Swift (1667–1745) were all premature infants, yet all lived a long vigorous life.

## HISTORY OF MODERN PEDIATRICS

Major events related to child health are listed in a chronological order in **Table 1**.

### Europe (United Kingdom, Belgium, Denmark, Italy, France, Germany and Sweden)

In 15th century four pediatric books were published in succession describing general pediatric ailments such as cough, ear infection, measles, smallpox, rheumatism and diarrhea. These were written by Paulus Bagellardus (Italy, 1472, *De Infantium Aegritudinibus et Remediis*), Bartholomaeus Metlinger (Germany, 1473, *Ein Regiment der Jungerkinder*), Cornelius Roelans (Belgium, 1483, no title) and Heinrich von Louffenburg (Germany, 1491, *Versehung des Leibs*).

This was followed by detailed description of diseases in children. Eucharius Roesslin (Germany, early 16th century) wrote a book on *Midwifery and Pediatrics*, which reviewed 35 common ailments including many infections. Faventinus de Victorious (Italy, 1544) published a book with chapter on aphthous ulcers, measles and smallpox. Thomas Phaer (England, 1544) published the first English language pediatric book, “*The Boke of Chyldren*” with chapters on meningitis, diseases of the ear, quinsy, diarrheal disorders, worm infestations, smallpox, measles, fever and a disease description similar to Kawasaki disease.

Many infectious disorders were described subsequently. Giovanne P Ingrassia (Italy, 1553) differentiated scarlet fever from measles. Hieronymus Mercurialis (Italy, 1583) wrote about *King’s evil* (scrofulous glands). Guillaume de Baillou (France, 1640) was the first to describe whooping cough as distinct entity covering the 1578 epidemic, as well as rubeola and scarlet fever. Johannes Sgambatus (Italy, 1620) made important descriptions of diphtheria while Thomas Bartholin (Denmark, 1646) described its contagious nature and mode of death by throttling.

The second English language book by Robert Pemell (1653) covered extensively many common infestations, otitis, oral ulcers, fevers, smallpox, measles and erysipelas. The third English book in 1664 by J Starsmare covered the same topics including *scrofula*. Thomas Sydenham (England) described chorea in 1686, measles in 1670 and scarlet fever in 1675. Willis (England, famous for *circle of Willis*) described pertussis in 1675. Walter Harris (England,

1689) wrote a book on *diseases of infants* covering plague, venereal diseases and strongly advocated inoculation against smallpox. This popular book had 18 editions and continued for another 53 years. John Fothergill (England, 1748) described ulcerative pharyngitis, diphtheria and scarlet fever.

Chickenpox was described in 1760 by François Boissier de Sauvages (France). In 1765 Nils Rosén von Rosenstein (Sweden) described scarlet fever of 1744 epidemic in detail including the post-streptococcal nephritis. The credit of describing tubercular meningitis in three clinical stages with autopsy findings goes to Robert Whytt (Scotland, 1768).

Michael Underwood’s (UK) book on *diseases of children* in 1784 was probably the best early published treatise on pediatric diseases. It had 17 editions and provided first descriptions of poliomyelitis and sclerema. Neonatal tetanus was first described by Joseph Clarke (Ireland) 1789. In the same year Edward Jenner published his report of 23 years of vaccination to prevent variola (smallpox).

By late 1700s and early 1800s, the need to attend specifically to the care, development, and diseases of children became more apparent and specialization in pediatrics evolved, particularly in Germany and France. *The Society for Infant Therapeutics* was formed in Germany in 1883. The British Pediatric Association was established in 1928 with George Frederic Still as the first president. The Royal College of Paediatrics and Child Health status was granted to British Paediatric Association in 1996. Its official journal “*Archives of Diseases in Childhood*” started its publication in 1926.

The first generally accepted pediatric hospital in Europe, the *Hôpital des Enfants Malades* (Hospital for Sick Children), opened in Paris in June 1802. The famous Great Ormond Street Children’s Hospital of London was established by Charles West in 1848 followed by Hospital for Children at Edinburgh in 1856.

### Pediatrics in the USA

The Father of American Pediatrics is considered to be Abraham Jacobi (1830–1919), a German pediatrician, who arrived in New York in 1853 and established the pediatrics chair at the New York Medical College in 1861. He is credited with the organization of the first pediatric society, publication of pediatric journal and development of pediatric departments in New York hospitals. He was a prolific writer and taught extensively about the feeding and hygiene of children. He, in association with pioneers such as Luther Emmett Holt in New York, J Forsyth Meigs in Philadelphia, and William McKim Marriott in St. Louis rapidly expanded the specialty through their writings and teachings. The first independent pediatrics hospital was founded in Philadelphia in 1855 followed by Boston (Massachusetts) in 1869. The American Academy of Pediatrics was established in 1930 and the American Board of Pediatrics in 1933.

Luther E Holt Sr., who succeeded Jacobi, wrote the book, “*The Care and Feeding of Children*” in 1894, which was later developed into the “*Holt’s Pediatrics*”. J P Crozier published “*The Diseases of Infants and Children*”, which in turn became Griffith and Mitchell’s “*Pediatrics*”, then Mitchell and Nelson’s “*Pediatrics*”; Waldo E. Nelson’s “*Pediatrics*” in 1954, and in 1984 “*Nelson’s Pediatrics*”, edited by Richard Behrman. It has been the world’s most trusted pediatrics resource for over 80 years. Pediatrics specialties have developed in diagnosis and management with approach of intrauterine diagnosis and treatment, identifying genetic disorders and study of genomics. The advances continue to provide the medical community with new diagnostic tools and therapies. Today in addition to general pediatrics, pediatricians can choose to specialize in a number of fields, including:

- Adolescent medicine
- Child abuse

**Table 1** History of major events related to pediatrics

<i>Year</i>	<i>Pioneer</i>	<i>Event</i>
1789	Edward Jenner, England	Cowpox vaccination for smallpox, first vaccine for any disease
1789	Benjamin Rush, USA	Description of cholera infantum, summer diarrhea
1818	James Blundell, England	First successful human blood transfusion for postpartum hemorrhage
1857	Louis Pasteur, France	Identification of microbes as a cause of disease
1865	Gregor Mendel, Austria	Principles of heredity
1882	Robert Koch, Germany	Discovery of the tubercular bacillus; Koch's postulates
1885	Louis Pasteur, France	Rabies vaccine; pasteurization of milk
1890	Emil von Behring, Germany	Discovery of diphtheria toxin and antitoxins
1895	Wilhelm C Roentgen, Germany	Discovery of radiograph (X-ray)
1900	Karl Landsteiner, Austria	Discovery of blood groups
1908	Archibald Garrod, England	Inborn errors of metabolism
1910	James Herrick, USA	Sickle cell anemia
1913	Bela Schick, USA	Schick test for immunity to diphtheria
1921	Edward Mellanby, England	Vitamin D deficiency causes rickets
1921	Thomas B Cooley, USA	Thalassemia major
1922	Frederick G Banting and Charles H Best, Canada	Discovery of insulin to treat diabetes mellitus
1923	Alexander Thomas Glenny, England and Gaston Ramon, France	Diphtheria toxoid for active immunization
1926	Louis W Sauer, USA	Vaccine against whooping cough (pertussis)
1927	Albert Calmette and Camille Guérin, France	Vaccine against tuberculosis
1928	Alexander Fleming, England	Discovery of penicillin
1931	Alvin C Coburn, USA	Hemolytic streptococcal infection and rheumatic fever
1943	Selman A Waksman, USA	Discovery of streptomycin
1948	United Nations	The formation of WHO
1952	Virginia Apgar, USA	Development of the Apgar score
1952	James Watson and Francis Crick, England	Double-helix structure of DNA
1954	Jonas Salk, USA	Inactivated polio vaccine
1956	La Leche League, USA	Promotion of breastfeeding
1957	Albert Sabin, Poland/USA	Oral polio vaccine
1959	The United Nations	Declaration of the rights of child
1959	Mary Ellen Avery and John Mead, USA	Surfactant
1963	Robert Guthrie, USA	Screening test for phenylketonuria—newborn screening
1964	John Enders, USA	Vaccine against measles
1965	Louis Gluck, USA	First newborn intensive care unit
1966	Dilip Mahalanabis, India	Development of modified ORS in Kolkata
1967	Maurice Hilleman, USA	Vaccine against mumps
1970	Maurice Hilleman, USA	Vaccine against rubella
1974	Michiaki Takahashi, Japan	Vaccine against chickenpox (varicella)
1977	Robert Austrian, USA	Vaccine against pneumococcal pneumonia
1977	WHO	Eradication of smallpox from the world
1978	Robert Edwards and Patrick Steptoe, UK	First test tube baby—Louise Joy Brown
1981	Baruch Blumberg and Irving Millman, USA	Vaccine against hepatitis B
1981	Robert Gallo, USA	HIV (AIDS) virus identified
1986	Alec Jeffreys, England	DNA typing or genetic fingerprinting
1992	Maurice Hilleman, USA	Vaccine against hepatitis A
2000	Francis S Collins and J Craig Venter, USA	Mapping of human genome

- Developmental and behavioral pediatrics
- Neonatology
- Pediatric allergy and immunology
- Pediatric cardiology
- Pediatric critical care
- Pediatric dermatology
- Pediatric emergency medicine
- Pediatric endocrinology
- Pediatric gastroenterology-hepatology
- Pediatric hematology
- Pediatric infectious diseases
- Pediatric nephrology
- Pediatric neurology
- Pediatric oncology
- Pediatric ophthalmology
- Pediatric pulmonology
- Pediatric psychiatry
- Pediatric rheumatology

Other pediatric specialists especially those in pediatric surgery, pediatric urology or pediatric radiodiagnosis are not necessarily pediatricians; however they undergo training in their own fields, and then receive additional specialty pediatric training.

## HISTORY OF PEDIATRICS IN INDIA

Pediatrics made a formal beginning in Mumbai (erstwhile Bombay) in 1928, under the leadership of George Coelho, called the Father of Pediatrics in India. He was the head of the department of pediatrics at the Bai Jerbai Wadia Hospital for Children, the first independent children's hospital in India. In 1929, Dr Coelho started the *Association of Pediatrics of India* in Bombay in 1950. Pediatric departments soon came into existence at other centers, Nair Hospital, Mumbai (Shantilal Sheth), Patna (LSN Prasad), Delhi (Pran N Taneja) and Indore (JN Pohowalla).

In 1933, Dr K C Chaudhry founded the first independent pediatric journal namely, the "*Indian Journal of Pediatrics*"; in Kolkata (Calcutta). In 1948 he started the *Indian Pediatric Society*. By 1958, the Indian Pediatric Society organized nine national pediatric conferences in different cities and in 1961 the first Asian Pediatric Conference was held at New Delhi. His efforts to make pediatrics an independent subject are worth mentioning.

The state of Tamil Nadu has the honor and pride of having created the first chair of professor of pediatrics in India at the Madras Medical College (Chennai) in 1948 with the appointment of Professor ST Achar.

The Indian Pediatric Society and the Association of Pediatricians of India combined to form the *Indian Academy of Pediatrics (IAP)* as the single representative body of pediatricians of India and the first national conference of the IAP was held in Pune in 1964. The official journal of the IAP "*Indian Pediatrics*", incorporated the "*Indian Journal of Child Health*" and the "*Journal of the Indian Pediatric Society*" and commenced publication in January 1964 from Kolkata.

The academy has promoted different specialties in the field of pediatrics through its various chapters. One of the major activities undertaken by the IAP since its inception is to organize continuing medical education programs all over the country. IAP has its office in Mumbai while Delhi is the seat of its official publication, "*Indian Pediatrics*".

## Pediatric Education in India

Nagpur (University of Bombay) was the first to start pediatrics examination in MBBS. Medical Council of India decided in 1997 that pediatrics will be a separate subject for examination of undergraduate (MBBS) training. The first postgraduate course for

diploma in child health was started at Bai Jerbai Wadia Hospital for Children in 1944 under University of Bombay (Mumbai) in 1946. First MD pediatrics course was also started at Nagpur.

Doctorate of Medicine (DM) courses were started late with gastroenterology in Postgraduate Institute of Medical Education and Research (PGIMER) at Chandigarh in 1989, followed Sanjay Gandhi Postgraduate Institute of Medical Sciences (SGPGIMS), Lucknow in 2009. DM in neonatology also began at PGIMER, Chandigarh in 1989. Subsequently DM neonatology courses have begun in other centres including All-India Institute of Medical Sciences (AIIMS), New Delhi. In 1991 SGPGIMS, Lucknow started DM in clinical genetics and reserved one seat each for pediatric postgraduates for DM courses in neurology, cardiology, gastroenterology and immunology. AIIMS, New Delhi now offers DM courses in pediatric neurology (2009), nephrology (2013) and pulmonology (2013). PGIMER, Chandigarh offers DM courses in pediatric critical care, pediatric hemato-oncology, child and adolescent psychiatry, and pediatric rheumatology (2013). The first MCh course in pediatric surgery was started at AIIMS, New Delhi in 1972.

## Major Achievements in Child Health and Care in India

By 1938, when American Academy of Pediatrics celebrated its 50th anniversary, US achievements related to child care were demonstrated by the following indices—life expectancy of more than 60 years, infant mortality rate (IMR) of 55/1000, and neonatal mortality rate (NMR) of 30/1000. It is heartening to note that the 50th year (2013) of IAP was celebrated with a life expectancy for men 62.4 and women 64.2 years; IMR of 50/1000 (in the year 2009) and NMR of 31/1000 (in the year 2011). In January 2014, WHO declared India *polio free* as the last case of paralytic polio was seen on 13th January 2011 in Kolkata.

Launched on 2nd October 1975, Integrated Child Development Scheme (ICDS) today represents one of the world's largest and most unique programs for early childhood development. ICDS is the foremost symbol of India's commitment to her children, India's response to the challenge of providing preschool education on one hand and breaking the vicious cycle of malnutrition, morbidity, reduced learning capacity and mortality, on the other.

## Chapter 1.2

# 20 Milestones in the History of Pediatrics

Santosh K Bhargava

In the history of world medicine there have been numerous remarkable milestones which have changed the course of disease. The present chapter describes milestones which are especially relevant or exclusive to pediatrics from ancient times to contemporary period and their current relevance in our time.

## EMERGENCE OF THE FIELD OF PEDIATRICS

The first description of pediatrics in our ancient scriptures is in the "*Sushruta Samhita*" in 800–1000 BC. Later descriptions of the medical care of children appear in 2nd century AD by Soraneus in Greece; and in the string of Rhazes in Persia in 865–925 AD. The first printed published book on diseases of children by Bagellardus (please see Chapter 1) entitled "*Little book on Diseases of Children*" appeared in 1472. The first children's hospital *Hôpital des Enfants Malades* (French = Hospital for Sick Children), was established in Paris in 1802. Dr Abraham Jacobi's sustained publications in New York Medical Journal helped further establish the field of pediatrics. As pediatrics extended its scope in clinical practice, it was recognized as an independent discipline in last century.

## SURVIVAL OF THE CHILD

It is believed that child survival has been the prime concern of the society. In ancient times surprisingly many societies and cultures aimed to destroy rather than save majority of newborns for varied reasons for being girls or for sacrificial and economic reasons. It is ironical that attention to child survival occurred through the needs of French armies to compensate for losses of fighting men rather than as a social measure. In 18th century half the human race died in infancy and this varied from 100 to 250 per 1000 births through late 19th century. As the appalling situation on infant mortality dawned on leaders, health and welfare measures were introduced. It continued to decline in some countries to single digit, but it remains a challenge to many countries including India where several intervention programs, such as Integrated Management of Neonatal and Childhood Illness, were introduced but the results were not as expected. Globally under five, infant and neonatal mortality rates are an important parameter of human development index and hence child survival is now universally a national child health priority in the world.

## THE ORIGIN OF DISEASE: THE GERM THEORY

The germ theory was proposed in the 16th century but it was only from the 17th century onwards that it began to be accepted. In brief, it states that some diseases are caused by microorganisms which are too small to be visible to naked eye. It remained unproven until Robert Koch in 1877 identified tubercle bacilli as the causative organism for tuberculosis. Thereafter, Louis Pasteur, in 1882 propounded the *germ theory of disease* by demonstrating that specific bacteria cause specific diseases such as anthrax. Classically, he discovered the pathology of the puerperal fever and the pyogenic vibrio in the blood, and suggested using boric acid to kill these microorganisms before and after confinement. In modern times we use this knowledge acquired through centuries of research and observations to successfully treat and prevent numerous infectious diseases of childhood.

## THE DEVELOPMENT OF VACCINES

One of the most famous milestones in the history of medicine is the inoculation of children and adults with dried scab material recovered from smallpox patients by variolation technique in 17th and 18th centuries. It was Edward Jenner in 1796 who first vaccinated with smallpox vaccine. Initially the development of vaccines was slow. But in last several decades new scientific discoveries and technologies led to rapid advances in virology, molecular biology, and vaccinology. Currently, vaccination is available against numerous infectious diseases which led to their sharp decline. Through vaccination, scientists and physicians were not only able to offer protection but eradicated diseases like smallpox globally and poliomyelitis in many countries, including India.

## THE DEVELOPMENT OF ANTIMICROBIAL THERAPY

In the 18th century, physicians used carminatives and blue pigments for treating infections and disease. The German physician Domas successfully used a synthetic red dye prontosil for surgically acquired streptococcal infection. Later in 1932, he discovered sulfonamides which saved many lives from acute infections including rheumatic fever. The miracle drug *penicillin* was discovered by Alexander Fleming in 1928 but was not fully used for treatment until 1940s when Florey and Chain produced it commercially. Since then, scientists across the world have discovered numerous antibiotics, antifungal, antiviral, and antiparasitic drugs. Antibacterial group of drugs such as penicillin, tetracycline, aminoglycosides, cephalosporin, macrolides, and antitubercular drugs have dramatically reduced morbidity and mortality. On the other hand, bacteria and microbes continue to develop drug resistance which is now presenting a major challenge to researchers and clinicians.

## THE DEVELOPMENT OF PEDIATRICS FOR PRIMARY AND SPECIALTY CARE

In ancient times children died or suffered largely because of diseases caused by environment, sanitation, hunger or unrecognized causes. In the 17th to 19th century infections such as diarrhea, typhoid, tuberculosis and pneumonia caused many deaths. These diseases are still prevalent in the 21st century. The patterns of diseases changed from infectious to noninfectious diseases, and diseases not amenable to antimicrobial therapy. Over time, increasingly morbidity and mortality was observed from multifactorial systemic diseases related to system dysfunction and grouped as cardiovascular, respiratory, neurological, and gastrointestinal diseases. Pediatrics which initially developed as primary care medicine has now many specialty and super specialties under its umbrella. This has led to unprecedented advances in the care of children with heart disease, lung disease, childhood cancer, prematurity, etc.

## THE DEVELOPMENT OF NEONATOLOGY

In the later half of 20th century, the newborn infant was increasingly recognized as a distinct challenge needing special attention and special newborn care units were developed. Gradually, the newborn care developed into the triage system of primary, secondary, tertiary and regionalization care. In 1952, Virginia Apgar developed the *Apgar score* helping in identification of severity of birth asphyxia. Newborn care made rapid progress with double volume exchange transfusion for hemolytic disease, treatment of patent ductus arteriosus, advent of phototherapy, care of low birthweight and preterms, and recognition of oxygen toxicity. Fetal growth curves were published by Lubchenco from USA in 1967 and by Ghosh and Bhargava in 1969 from India.

These classified newborns as being small, appropriate, or large for gestational age. Surfactant deficiency was recognized as a cause of hyaline membrane disease and treated with surfactant replacement therapy. Respiratory failure outcome improved with availability of blood gas analysis, assisted pulmonary ventilation and ventilator support. The focus currently is on noninvasive ventilation for minimizing lung injury. Finding that room air is as good as enriched oxygen air for resuscitation of newborn, was another remarkable research application.

The developed world continued to make rapid progress with advanced technology but these remained beyond the reach of most in many parts of world including India and resulted in slow decline in neonatal mortality. It was the development of *Essential Newborn Care (ENC)* program conceptualized in 1994 by Bhargava and colleagues and pioneered by the Government of India and National Neonatology Forum India which made the real breakthrough in newborn care for this part of the world. ENC is now a cornerstone for delivery of newborn care in India and several developing countries. The rapid advances in newborn care resulted in dramatic improvement in survival of newborns including the very premature and low birthweight infants.

### EXCLUSIVE BREASTFEEDING

The fact that breastmilk is best for an infant is known from antiquity. The practice to breastfeed all newborns declined in 20th and 21st century in many countries. The emergence of social groups such as *La Leche League*, established in 1956, vigorously promoted and advocated breastfeeding and fought the battles of feeding bottles. In 1960s, commercial baby formula was marketed and competed with breastmilk. The publicity, convenience, social culture and beliefs severely affected breastfeeding practices. This prompted professionals, government and non-government agencies to act. Their efforts resulted in World Health Organization (WHO) and United Nations Children's Fund (UNICEF) bringing in the *International Code of Marketing of Breastmilk Substitutes* in 1981. This was adopted with modifications by many countries including India. The current recommendation is for *exclusive breastfeeding for the first 6 months* of life. It has shown immediate and long-term advantages in prevention of infections, adult diseases, and food allergy.

### THE WELL BABY CLINICS, ROAD TO HEALTH CARD, AND UNDER-5 CLINICS

The concept that mother and child should be seen as a pair was responsible for special infant clinics known as *Well Baby Clinics*. In 1892, Pierre Robin encouraged mothers to bring their healthy infants for weighing, which spread rapidly in Europe. In US the clinics focused on clean milk to prevent infections. In 1974 David Morley introduced the *Road to Health Card* to monitor the growth of infants and children serial weighing. This identified faltering growth in children at the earliest. These were further modified to suit *under-5 clinics*. Today, under-5 clinics and well baby clinics are norms offering inclusive preventive advice on infant care, feeding, immunization, growth, and development.

### GROWTH MONITORING

Weighing the child to monitor his/her well-being began to be practiced in late 19th century. Serial measurement at different ages led to the construction of Harvard growth curves, USA and Tanner's growth curves, UK which became standard reference for children. These were followed by the National Center for Health Statistics (NCHS) growth curves developed for US children. Subsequently these were adapted for international use by Centers for Disease

Control (CDC) and WHO. In 2007, WHO released its own growth curves for 0–5 year olds after a multicountry study in which six countries, including India, participated.

An interesting analysis by the Cohort group of pooled data of similar cohorts from five countries Institute of Nutrition of Central America and Panama (Guatemala); Cebu (Philippines); Pelotas (Brazil); B2 Twenty (South Africa); and The New Delhi Birth Cohort (India) showed adverse effect of maternal and child undernutrition on adult diseases, human capital development including income, education and height and birthweight of the next offspring. They also showed that accelerated growth in first 2 years benefits adult life but rapid weight gain after 2 years of age leads to increased fat mass, adiposity and overweight. Growth monitoring is thus a simple effective tool to assess child's nutrition and well-being.

### EVOLUTION OF DEVELOPMENTAL PEDIATRICS

Child development studies began in late 19th century. Several standard developmental scales are now available for assessment of development, behavior, and intelligence from newborn to adolescence periods. These tools have been modified or adapted by individual countries for their use because development is highly culture depended. In India, adaptations have been worked out at Baroda and Trivandrum.

The sharp increase in survival of low birthweight, extremely premature infants has necessitated prompt recognition of developmental and other deficits. Friedman coined the term *Behavioral Pediatrics* and defined it as "*an area within pediatrics which focuses in psychological, social and learning problem of children and adolescence*". This has now developed into the science of developmental pediatrics and behavioral sciences. The focus here is on multi-disciplinary team approach with pediatrician, developmental pediatrician, therapists, speech therapist and others. Specialists in this area investigate and manage communication delays, autism, attention deficit disorders, and other learning disabilities that require early diagnosis and intervention.

### ORAL REHYDRATION SALT (ORS) SOLUTION

Oral rehydration salt solution is one of the most acclaimed advances in modern science for treatment of dehydration and diarrhea. The use of oral solutions for fluid loss is described from ancient times. Bengali and US research scientists in 1960s discovered a simple electrolyte solution which was formulated to treat cholera epidemic patients in Bangladesh at the International Centre for Diarrhoeal Disease Research, Bangladesh. The development occurred as a dire need as logistically it was impossible to provide intravenous fluid therapy in villages. Cash and David Nalin first and later Mahalanabis and colleagues demonstrated its successful use by scientific studies on large scale. The WHO recommends a standard formulation, which is now universally used and can be modified for different uses. This *simple solution* has resolved a monumental problem and saved millions of lives till date.

### SOCIAL IMPLICATIONS OF CHILD HEALTH

Despite all campaigns and awareness the plight of child in social milieu continues. He/she is neglected and exploited in every possible way in health, education; nutrition, violence, sexual abuse and as child labor. Jacobi in 19th century said that "*it is not enough for physicians to work by the bedside in a hospital but it is equally important for him to influence hospital boards, health department legislator, judge and the seat of council*". Pediatricians and socially conscious people have to be proactive to protect and plead for the child. It is the sustained social activism which got results.

*Battered child syndrome* description by Kempke in 1962 made it a medicolegal and social issue. Sustained focus on abortions, killing of the girl child, child marriage, child abuse, violence and labor all led to enactments of laws benefiting children.

## THE RIGHTS OF CHILD

The continuous assault on children's physical, mental, and emotional health, exploitation, employment in hazardous professions, absent or limited rights as human being has been building a guilty conscience in society. It took almost 6 decades for government and non-government organizations to convene UN convention on *Rights of the Child*. It was passed as an international declaration in 1990. The Rights of the Child Declaration confers rights for a life with dignity, protection from exploitation, and rights to education, love, play, be the first to get help, and have a name and family. In 1991, India and several countries ratified this declaration.

## GENETICS IN PEDIATRICS

Genetics emerged as a specialty about half a century ago. Many pediatrics departments took lead in this field because of the recognition of genetic disorders, syndromes and malformations in children. Today genetics has developed into a specialized subject and has expanded to prenatal screening of diseases, cytogenetic, molecular genetics and in diagnosis of several disorders including asthma, growth failure, hypertension, and diabetes mellitus type 2. The gene therapy is beginning to be used for some diseases and has enormous potential.

## GENOMICS, PROTEOMICS AND METABOLOMICS

The development of *genomics* was the natural progression of research in genetics. From single gene identification it progressed to the formation of *Human Genome Project* and finally to mapping of the *human genome* in 2003. Genome sequence data now provides an opportunity for clinical application of genetic information. Its application to pediatrics is similar to genetics and for population studies. The term *proteomics* coined in 1994, seeks to investigate protein functions as it relates to its environment and biological setting. It was believed that identification of specific proteins will lead to development of new drugs and biomarkers. These are studied in body fluids, cells and tissues and have vast potential in research and clinical application in oncology, cardiology, neonatology, vaccine research and others. *Metabolomics* derives its name from *metabolome* a term described for a collection of metabolites in body fluids, tissues, organs and biological cells. The application includes analysis of body biological fluid through noninvasive or minimal invasive procedures in the fields of nutrition, prenatal disease, and neonatology. It is likely to help detection of diseases, classify patients based on biochemical profiles, and monitor disease progress.

## BIOINFORMATICS IN PEDIATRICS

Development in *bioinformatics* is transforming medical research by playing a critical role in understanding the molecular basis of diseases, identifying markers for disease predisposition, diagnosis

and prognosis of disease, and developing better vaccines and therapeutics. Considering critical role in rapid diagnosis, better therapeutic and efficient vaccines, bioinformatics is going to play a major role in reducing neonatal and child morbidity and mortality.

## FETAL MEDICINE AND SURGERY

Fetal medicine is one of the recent rapidly emerging specialties. It intends to save fetal life and help reach a normal outcome. The fetal well-being needs careful assessment by obtaining maternal and pregnancy history, and conducting physical examination. Currently the most important assessment is by ultrasonography for fetal growth; malformations, placental blood flow, etc. Laboratory tests and amniocentesis are performed for high risk pregnancies. Fetal surgery is possible either by minimal or major surgical intervention. Minimal surgery is by fetoscopy used for fetal transfusion, bladder neck obstruction and certain congenital heart ailments. The major fetal surgery is now available for neural tube defect and diaphragmatic hernia, through a cesarean section.

## DEVELOPMENTAL ORIGIN OF ADULT DISEASE: BARKER'S HYPOTHESIS

It was the Barker's hypothesis of *fetal origins of adult disease* that caused interest in the fetomaternal metabolism, nutrition, environment, and fetal growth. His studies and others who confirmed later showed that size at birth is related to the risk of developing disease in later life. Significant relationship was found between reduced birthweight and increased risk of coronary heart disease, diabetes, hypertension and stroke in adulthood. Most believers in his hypothesis believe that these relationships are those of fetal programming by nutritional stimuli or excess fetal glucocorticoid exposure. The New Delhi Birth Cohort has also confirmed the findings and observations made by David Barker. It has concluded that it is possible to track these diseases with serial body growth measurement from early childhood to adulthood.

## ETHICS IN PEDIATRICS

Ethics in pediatric practice is being viewed with an increasing interest since pediatrician is the custodian of the child who may not be able to express verbally. The pediatrician has to put the interest of the child as foremost. Pediatrician should follow general code of ethics in patient care, surgical intervention, investigations or research. The general principles include respecting individual autonomy, competence, beneficence with the honest truth, assure and maintain confidentiality and avoidance of personal bias. One should be extremely cautious about conflict of interest and be frank to admit that all medical care has limitation. It is always helpful to obtain written consent of parents or wherever applicable from the child.

## Chapter 1.3

# Status of Child Health

RN Srivastava

Every child is born with a development potential that is determined by genetic and environmental factors. It is the duty and responsibility of everyone (parents, community, civil society and the governments) to ensure that he/she achieves that. Whereas pediatricians are chiefly involved with care of the sick child and health related issues, they must also be cognizant of various other factors that affect child health and development and make efforts to tackle adverse elements.

Globally, the child has been defined as one below the age of 18 years. That characterization widens the scope of child health. Traditionally, pediatricians have been mostly concerned with problems of the younger child and the neonate. Various issues during the adolescent period and the transition to adulthood also need to be addressed by pediatricians.

## GLOBAL PERSPECTIVES OF CHILD HEALTH

The WHO defines health as “*a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity*”. However, most low- and middle-income countries would be satisfied with *abolition or at least control of common diseases and provision of adequate nutrition*. Early development, education, care and protection are crucial for children. Various aspects of child health are vastly different between affluent countries and economically poor countries, which account for the majority of the world’s population. Understandably, there is a small proportion of underprivileged children in rich countries as well, and affluent population in the developing nations. Availability of proper health care, economic status and education greatly impact child health and development. It is estimated that 75 countries having low- and middle-income account for more than 95% of maternal and child deaths (UNICEF, 2010). A lack of financial protection for the costs of health care and failure to avail of the facilities wherever available are chiefly responsible for these and need to be identified and appropriately addressed by different countries (Lancet, 2013).

## Child Health in Affluent Nations

The economically developed, educated countries have almost eliminated common infections and preventable diseases and nutritional deficiency. Improved sanitation and hygiene, provision of safe water, universal application of immunizations, and availability of health care have resulted in a vastly improved health status of the child population. However, various socioeconomic factors have led to emergence of fresh challenges. Besides, there is a risk of importing diseases, such as malaria, dengue fever and viral infections, from travelers from other countries.

Several problems are particularly important in rich countries, but are of increasing concern in low- and middle-income countries. The latter are facing the double burden of infections and communicable diseases as well as noncommunicable diseases and lifestyle related disorders.

## Obesity and Metabolic Syndrome

Obesity has assumed epidemic proportions in affluent countries. The number of overweight children in the USA has reportedly doubled in children and quadrupled in adolescents over the past 30 years. In 2012 more than one-third of children and adolescents

were obese. Obesity is also a problem in developing countries in Africa, China and India. About 5% of school children are reportedly obese. Severe obesity is associated with the metabolic syndrome, type 2 diabetes mellitus and nonalcoholic fatty liver disease. Obesity also leads to hypertension and renal disease and joint problems. Sedentary habits, and excessive consumption of food containing carbohydrate, fats and salt have become the norm and very difficult to modify. Childhood obesity is an important contributor to adult obesity and diabetes.

## Substance Abuse and Sexually Transmitted Diseases

There is a high incidence of substance abuse in adolescents, which is reflective of the family and societal mores. There is a high rate of mortality from drug abuse related automobile accidents and overdosage. The USA has some of the highest rates of sexually transmitted diseases (STDs) in the industrialized nations. In a study by Center for Disease Control, one in four girls between the ages of 14 and 19 was found to have at least one STD caused by human papillomavirus, chlamydia, herpes simplex virus, or trichomonas. Substance abuse (alcohol, tobacco, cannabis, opiates, glue sniffing) is common in children in India and appears to be increasing, especially in street children and adolescents.

## Child Health Status in Developing Countries

Child health in developing countries is greatly influenced by poverty, illiteracy, misinformation and traditional adverse beliefs. A lack of availability of safe water, poor sanitation and hygiene, environmental pollution and overcrowded living conditions play important roles in the prevalence of diseases and disability. Large family size, denial of proper health care and education adversely affect child development. Among the small, affluent proportion of the population, lifestyle diseases and other problems seen in developed countries are also being increasingly encountered in economically poor countries. There are large differences in child health status in urban and rural communities, the latter comprising 70% of more of the population. Modern medical care facilities are mostly confined to big and small cities. Various health parameters, such as maternal and infant mortality rate (IMR), under-5 mortality in regions within a country, where literacy rates are high and health care provided, are closer to those seen in affluent countries. Thus national statistical information or even regional data within a country need to be carefully evaluated and stratified according to demographic and socioeconomic profile.

## Maternal and Perinatal Care and Infant Mortality

Maternal undernutrition and small stature are closely related to low birthweight babies. The mortality rates are high in such babies since expert perinatal management is often not available.

## Infant Mortality

Infant mortality rate (IMR) is regarded as an indicator of the level of health in a country. There has been a consistent decline in IMR in India from around 80 per 1,000 livebirths in 1981 to 40 in 2014; the current IMR remains high as compared to developed countries. The national figure is high chiefly due to poor performance in large northern states (>50 in MP, Odisha, UP). More than two-thirds of infant deaths occur before 1 month of age, in the neonatal period. The decline in IMR is sharper in urban areas and is influenced by maternal factors such as nutrition, anemia, age below 18 years, birth spacing, level of education and overall socioeconomic conditions. There has been a small or no decline in early neonatal mortality rate, an indicator of the quality of perinatal care, which remains at 30. **Table 1** shows the IMR in certain developed countries and those with low- or middle-income population.

**Table 1** Infant mortality rates (IMR; per 1,000 livebirths per year) in some developed and developing countries in 2014

### Immunizations

In most countries, vaccinations against common diseases are freely available. However, adequate *routine* vaccination coverage varies widely. Ignorance, suspicions and misinformation of the benefits of protection from such procedures among illiterate communities hinder universal application of vaccinations and continued morbidity and often serious complications from preventable diseases.

### Common Early Childhood Illnesses

In underprivileged communities, rural and urban, common illnesses, such as diarrhea, upper respiratory infections, skin infections, are often accepted as parts of *growing up* and proper medical attention is not provided. Such recurrent episodes adversely impact nutrition and growth.

### Undernutrition

Information about the importance of breastfeeding and oral rehydration management of diarrhea is widely known, and the incidence of severe forms of undernutrition has markedly decreased. However, milder forms remain very common. Although the prevalence of stunting of linear growth of children younger than 5 years has decreased during the past two decades, it is high in South Asia and Sub-Saharan Africa. Globally, it affected at least 165 million children in 2011 whereas wasting affected at least 52 million. Specific nutrient deficiency of iron, iodine, vitamin A and D are frequent and together with stunting adversely affect attainment of full developmental potential. It is estimated that various morbidities of undernutrition combined with suboptimal breastfeeding may cause 3.1 million deaths annually (45% of all child deaths in 2011).

### Common Diseases, Still Widely Prevalent

A large number of diseases can be controlled with provision of safe water, application of basic hygienic and sanitation measures, vector control and immunizations. Unfortunately, these facilities are inadequate in developing countries resulting in a very high morbidity that adversely impacts child health.

### Diarrheal Diseases and Other Waterborne Infections

Lack of safe water is responsible for a heavy burden of diarrhea (cholera in several countries), dysentery, typhoid and hepatitis A. Ensuring safe water and proper sanitation is very difficult in overcrowded urban localities. Increasing migration to cities and huge construction activities put heavy demands on water. In rural areas access to water is often difficult. The costs and technological

limitations in providing safe water present formidable challenges. However, information and functional education about the dangers from *unsafe* drinking water and poor sanitation and harmful traditional practices can be provided to the underprivileged population, which would lead to changes in behavior and habits and thus help toward control of several common diseases. Infant and under-5 mortality rates are lower in communities with access to safe water and improved toilets.

### Tuberculosis

Tuberculosis continues to remain a very difficult public health problem in India and many developing countries. Overcrowded living conditions, delay in diagnosis, inadequate treatment (despite provision of medications free of cost) and multidrug resistance contribute to the high prevalence and considerable mortality from tuberculosis (2 million every year, mostly in developing countries). In India 3–4 million children have tuberculosis and about 94 million are at risk of developing the disease. The annual infection rate is between 3% and 5%, which may be higher because of lack of early diagnosis.

### Malaria

Malaria is an important cause of illness and death in many parts of the world, especially Sub-Saharan Africa. About 600,000 children in Africa die of malaria each year. Falciparum malaria is common in several states in India and presents a particularly challenging problem with difficulties in diagnosis and drug resistance. Mosquito control measures including the use of medicated mosquito curtains and larvicide agents have been employed. Global efforts are being made to develop an effective malaria vaccine.

### HIV Infection, Viral Hepatitis

A lack of institution of proper preventive measures continues to be responsible for high incidence of HIV infections in many developing countries particularly in Africa. Hepatitis B is also very common as vaccinations are not widely available.

### Early Development and Education

A stimulatory environment and opportunities for preschool learning experiences are severely restricted for the majority of children in developing countries. In India, the Right to Education ensuring free of cost primary education was enacted in 2009. School enrolments have increased but the proportion of school dropouts remains very high. School infrastructure facilities are very often inadequate and educational achievements remain limited. A large proportion of poorly literate and physically underdeveloped population cannot fully contribute to national development.

### Child Abuse and Neglect, Child Labor, Natural and Man-made Disasters

Over the past three decades, global concern has been raised over the very complex problems of child abuse and neglect. Inadequate care and lack of education hinder the child health status and achievement of his/her developmental potential. The dimensions of the various issues vary greatly in rich and poor countries. Physical abuse, exploitation, child labor, child sexual abuse and trafficking are particularly common in developing countries. Millions of children in poor countries, who ought to be in schools, are working in organized or nonformal work, often in hazardous conditions. Child physical and sexual abuses are also of major concern in Northern America and Europe. Children are highly vulnerable during natural (floods, earthquakes) or man-made conflicts (wars, internal conflicts). Besides the problems of diseases and nutrition, their education and learning suffer and adversely impact their long-term development.

One hundred and eighty-nine United Nations member States have pledged to achieve by 2015 several Millennium Development Goals (MDG) that include, among others, eradication of extreme poverty and hunger, universal primary education, and reduction by half the proportion of people without sustainable access to safe drinking water. However, in many countries these goals are not likely to be met with in near future. MDG related to child health will be discussed in the subsequent Chapter.

## CONCLUSION

Health status of children is greatly influenced by multiple factors that include availability of health care, socioeconomic status, literacy and traditional beliefs, family size, sanitation and hygiene and lifestyle habits. Within a country there are variations in health parameters between rich and poor, and rural and urban. High prevalence of many diseases, which have largely been eliminated in affluent countries, contributes to ill-health and mortality

in children in middle- and low-income countries. A wider, comprehensive approach is needed to identify the problems and institute appropriate remedial measures.

## Chapter 1.4

# Millennium Development Goals for Child Health

Raju C Shah, Pratima Shah, Kunal Ahya

In the last two decades of the last millennium, many international conferences were held to discuss issues related to poverty and childhood mortality without success. In the September 2000, a largest ever summit of 147 heads and representatives of 189 countries was organized to discuss the health and development issues. Participants of this summit agreed to the need of commitment to develop third world countries. In this Summit, a declaration of eight Millennium Development Goals (MDGs) was signed by all the participants. MDGs (**Fig. 1**) are aimed to get rid of poverty and improve humanity on a global level. The targets and indicators of MDGs form the guidelines for planning policy interventions and to monitor progress in human development and poverty reduction in the third world countries.

**Figure 1** The 8 Millennium Development Goals

Millennium Development Goals are a set of 8 goals, 18 targets, and 48 indicators adopted by United Nations (**Table 1**). The indicators are categorized according to the targets, for measuring the progress toward the individual targets. The MDGs in India are based on the framework provided by United Nations Development Group in 2003. Out of the 18 targets, 12 targets (targets 1–11 and target 18) are relevant to India. There are 35 indicators which correspond to the 12 targets. Even though the goals are depicted in general terms, the targets under them are more focused and further the indicators under each target are specifically outlined to define the expected level of achievements in well-defined areas and in a given time frame.

Millennium Development Goals have helped the government to do better planning at national and subnational levels and implement more intensive policies and programs. Various development schemes and programs are formulated and implemented under the Five Year Plans (FYP) in India. The goal of the 12th FYP (2012–2017) was to achieve *faster, more inclusive and sustainable growth*, which is in tune with the MDGs. **Table 2** shows the various plans implemented in India under the 12th FYP to achieve the MDGs. Of all these goals, the MDG 4 is related to child mortality, which can give us better indicator of overall improvement in health system. Millennium Development Goals for Health for India are listed below:

- Marshaling the required resources
- Strengthening health systems and institutions
- Scaling up effective priority interventions

- Empowering women and girls
- Mitigating food insecurity and reducing hunger and malnutrition
- Ensuring good governance and effective leadership in the stewardship of resources for development and health
- Improving water and sanitation services
- Ensuring a motivated workforce.

## MILLENNIUM DEVELOPMENT GOAL 4: REDUCE CHILD MORTALITY

The global under-5 mortality (U5MR) trend between 1970 and 2013 is shown in **Table 3**. The U5MR was around 143 per 1,000 livebirths in 1970 and decreased by slightly more than two-third to 44 per 1,000 livebirths in 2013.

The U5MR rate in India (**Fig. 2**) has declined from 125 per 1,000 livebirths in 1990 to 52 in 2012. As per the trend, India will achieve U5MR of 49 by 2015, missing the target by 7%. The infant mortality rate (IMR) in India has decreased by nearly 50% from 1990 to 2012 (**Fig. 3**). In 2012, the IMR has reached 42 per 1,000 livebirths. The IMR has reached to 40 in 2014, missing the target of 27 by 2015 as per the MDG goal.

The coverage at national level of the proportion of 12–23 months children immunized with measles vaccine has increased from 42.2% in 1992 to 74.1% in 2009. According to the trend, India is likely to cover about 89% children by 2015, falling short by around 11% for the target of 100%.

## ADDRESSING ISSUES OF CHILD MORTALITY

National Policy for Children was adopted by the Government of India on 26th April 2013. Guidelines outlined in the policy must be honored by the Government at the national, state and local level. The policy mentions the undeniable rights of every child like survival, health, nutrition, education, development, protection and participation. The policy states that the state shall take necessary measures to:

- Improve maternal health care, including antenatal care, safe delivery by skilled health personnel, postnatal care and nutritional support
- Address key causes and determinants of child mortality through interventions based on continuum of care, with emphasis on nutrition, safe drinking water, sanitation and health education
- Provide universal and affordable access to services for prevention, treatment, care and management of neonatal and childhood illnesses and protect children from all waterborne, vector borne, communicable and other childhood diseases.

The health of the mother has an important impact on the health of the child. Thus measures for improvement of mother's health are important for improving the survival of the newborn. Higher resources are allocated under National Rural Health Mission (NRHM) to states and districts with weak health indicators. The major programs addressing the needs of mother and children (at child care and child survival) are discussed below, in brief.

## Institutional Delivery through Janani Suraksha Yojana and Janani Shishu Suraksha Karyakram

To ensure skilled birth attendance by promoting institutional delivery will help reduce both maternal and neonatal mortality. *Janani Suraksha Yojana* provides cash assistance and encourages pregnant women to opt for institutional delivery. In *Janani Shishu Suraksha Karyakram*, the pregnant woman gets complete zero expense delivery including cesarean section operation, as well as transport, food, drugs and diagnostics.

**Table 1** Millennium Development Goals: Targets and indicators**Goal 1: Eradicate Extreme Poverty and Hunger**

**Target 1:** Between 1990 and 2015, halve the proportion of people whose income is less than one dollar a day

**Indicator 1A:** Poverty headcount ratio (percentage of population below the national poverty line)

**Indicator 2:** Poverty gap ratio

**Indicator 3:** Share of poorest quintile in national consumption

**Target 2:** Halve, between 1990 and 2015, the proportion of people who suffer from hunger

**Indicator 4:** Prevalence of underweight children under 3 years of age

**Goal 2: Achieve Universal Primary Education**

**Target 3:** Ensure that by 2015, children everywhere, boys and girls alike, will be able to complete a full course of primary education

**Indicator 6:** Net enrolment ratio in primary education

**Indicator 7:** Proportion of pupils starting Grade 1 who reach Grade 5

**Indicator 8:** Literacy rate of 15–24 years old

**Goal 3: Promote Gender Equality and Empower Women**

**Target 4:** Eliminate gender disparity in primary and secondary education, preferably by 2005, and in all levels of education, no later than 2015

**Indicator 9:** Ratio of girls to boys in primary, secondary and tertiary education

**Indicator 10:** Ratio of literate women to men, 15–24 years old

**Indicator 11:** Share of women in wage employment in the nonagricultural sector

**Indicator 12:** Proportion of seats held by women in National Parliament

**Goal 4: Reduce Child Mortality**

**Target 5:** Reduce by two third, between 1990 and 2015, the under-5 mortality rate

**Indicator 13:** Under-5 mortality rate

**Indicator 14:** Infant mortality rate

**Indicator 15:** Proportion of 1-year-old children immunized against measles

**Goal 5: Improve Maternal Health**

**Target 6:** Reduce by three quarters, between 1990 and 2015, the maternal mortality rate

**Indicator 16:** Maternal mortality ratio

**Indicator 17:** Proportion of births attended by skilled health personnel

**Goal 6: Combat HIV/AIDS, Malaria and Other Diseases**

**Target 7:** Have halted by 2015 and begun to reverse the spread of HIV/AIDS

**Indicator 18:** HIV prevalence among pregnant women aged 15–24 years

**Indicator 19:** Condom use rate of the contraceptive prevalence rate (condom use to overall contraceptive use among currently married women, 15–49 years percent)

**Indicator 19A:** Condom use at last high-risk sex (condom use rate among nonregular sex partners 15–24 years)

**Indicator 19B:** Percentage of population aged 15–24 years with comprehensive correct knowledge of HIV/AIDS

**Target 8:** Have halted by 2015 and begun to reverse the incidence of malaria and other major diseases

**Indicator 21:** Prevalence and death rates associated with malaria

**Indicator 22:** Proportion of population in malaria risk areas using effective malaria prevention and treatment measures (percentage of population covered under use of residuary spray in high-risk areas)

**Indicator 23:** Prevalence and death rates associated with tuberculosis

**Indicator 24:** Proportion of tuberculosis cases detected and cured under DOTS

**Goal 7: Ensure Environmental Sustainability**

**Target 9:** Integrate the principles of sustainable development into country policies and programs and reverse the loss of environmental resources

**Indicator 25:** Proportion of land area covered by forest

**Indicator 26:** Ratio of area protected (to maintain biological diversity) to surface area

**Indicator 27:** Energy use per unit of GDP (rupee)

**Indicator 28:** Carbon dioxide emissions per capita and consumption of ozone-depleting chlorofluorocarbons (ODP tons)

**Indicator 29:** Proportion of the households using solid fuels

**Target 10:** Halve, by 2015, the proportion of people without sustainable access to safe drinking water and basic sanitation

**Indicator 30:** Proportion of population with sustainable access to an improved water source, urban and rural

**Indicator 31:** Proportion of population with access to improved sanitation, urban and rural

**Target 11:** By 2020, to have achieved a significant improvement in the lives of at least 100 million slum dwellers

**Indicator 32:** Slum population as percentage of urban population

**Goal 8: Develop a Global Partnership for Development**

**Target 18:** In cooperation with the private sector, make available the benefits of new technologies, especially information and communication

**Indicator 47:** Telephone lines and cellular subscribers per 100 population

**Indicator 48A:** Internet subscribers per 100 population

**Indicator 48B:** Personal computers per 100 population

*Abbreviations:* DOTS, directly observed treatment, short-course; GDP, gross domestic product; ODP, ozone-depleting potential.

## Facility-based Newborn Care

*Special newborn care units* (SNCUs) are setup at district hospitals and medical colleges. These care for the sick newborn and are equipped with radiant warmer, phototherapy unit, oxygen hoods, infusion pumps, laryngoscope and endotracheal tubes, bag and mask, nasal cannulas and weighing scale. SNCU is a 12–20 bedded unit and requires four trained doctors and 10–12 nurses for round the clock services. Almost 400 SNCUs are now functional in the country.

*Newborn stabilization units* are setup at community health center/first referral units. These units provide services like resuscitation, provision of warmth, early initiation of breastfeeding, prevention of infection and cord care, supporting care including oxygen, IV fluids, provision for monitoring of vital signs including blood pressure and referral services. These are four-bedded units with trained doctors and nurses for stabilization of sick newborns.

*Newborn baby care corners* are setup in all facilities where deliveries are taking place. This is one-bedded facility attached to the labor room and operation theater for provision of essential newborn care. The services include resuscitation, provision of warmth, and prevention of infection and cord care and early initiation of breastfeeding. The equipment at newborn care corners include weighing scale, radiant warmer, suction machine and mucus sucker.

## Home-based Newborn Care

Home-based newborn care through Accredited Social Health Activist (ASHA) workers has been initiated to improve newborn care practices at the community level and for early detection and referral of sick newborn babies. All newborns will be visited by ASHA workers as per the specified schedule, up to 42 days of life. They have to ensure recording of weight of the newborn; BCG vaccination, first dose of oral polio vaccine and diphtheria, pertussis, and tetanus vaccination; both the mother and the newborn are safe till 42 days of the delivery; and that registration of birth has been done.

## Capacity Building of Health-care Providers

Trainings are conducted under NRHM to train doctors, nurses and auxiliary nurse midwife (ANM) for early diagnosis and case management of common ailments of children, as per the *Integrated Management of Neonatal and Child Illness* (IMNCI) strategy and *Navjat Shishu Suraksha Karyakram*.

Integrated Management of Neonatal and Child Illness includes interventions to prevent and manage the commonest major childhood illnesses which cause death, i.e., neonatal illnesses, acute respiratory infections, diarrhea, measles, malaria, and malnutrition. The objective is to implement IMNCI package at the household

**Table 3** Global morality rate (per 1,000 livebirths) for early neonatal, late neonatal, postneonatal, child and under-5 age from 1970–2013

Mortality rate	1970	1980	1990	2000	2013
Early neonatal (0–6 days)	31.4 (30.0–32.8)	26.7 (25.7–27.7)	22.6 (21.8–23.3)	19.8 (19.2–20.4)	14.0 (13.5–14.6)
Late neonatal (7–28 days)	16.8 (16.3–17.4)	12.8 (12.6–13.1)	9.3 (9.1–9.5)	7.2 (7.1–7.4)	4.4 (4.1–4.6)
Postneonatal (29–364 days)	48.1 (45.1–51.4)	36.5 (34.9–38.2)	27.6 (26.4–28.8)	22.2 (21.3–23.0)	13.2 (12.4–14.1)
Child (1–4 years)	54.1 (49.8–58.7)	38.7 (36.2–41.3)	27.9 (26.1–29.6)	22.1 (20.9–23.3)	13.1 (12.0–14.3)
Under-5 (0–4 years)	142.6 (138.5–146.9)	110.0 (108.1–111.7)	84.6 (83.3–85.9)	69.4 (68.5–70.4)	44.0 (41.9–46.3)

Source: Wang, et al. Global Burden Study. Lancet. 2014.

Figure 2 Trend in under-5 mortality rate (India)

Figure 3 Trend in infant mortality rate (India)

level and subcenter, primary health center level, to provide a comprehensive newborn and child health services to address major neonatal and childhood illnesses. More than 500 districts and 5 lakh health-care providers have been trained in IMNCI.

*Navjat Shishu Suraksha Karyakram* program is launched to address basic newborn care and resuscitation, and issues at birth, i.e., prevention of hypothermia, prevention of infection, and early initiation of breastfeeding. The objective of this program is to have one person trained in basic newborn care and resuscitation available at every delivery.

### Management of Malnutrition and Other Morbidities

Malnutrition reduces immunity of children to infections and hence increasing mortality and morbidity among children. Exclusive breastfeeding is promoted for first 6 months of life as it reduces neonatal mortality. Appropriate infant and young child feeding practices are also promoted. For prevention of anemia, iron and

folic acid are provided to the children. Almost 600 nutritional rehabilitation centers have been established for management of severe acute malnutrition, across the country. Reduction in morbidity and mortality due to acute respiratory infections and diarrheal diseases is encouraged by early identification of cases and managing them properly. Promotion of zinc and oral rehydration salts supplies is ensured. Micronutrient malnutrition is addressed by supplementation with micronutrients through supplies of vitamin A and iron folic acid tablets.

### Universal Immunization Program

Immunization program of India is one of the largest immunization programs in the world. Under this program, Government of India is providing vaccination to prevent seven vaccine preventable diseases, i.e., diphtheria, pertussis, tetanus, polio, measles, BCG, and hepatitis B. *Haemophilus Influenza B* vaccine as part of a liquid pentavalent vaccine is also introduced in many states recently. Some newer initiatives have been introduced to strengthen routine

immunization, e.g., provision of auto disable syringe to ensure injection safety.

### Mother and Child Tracking System

A web based mother and child tracking system has been introduced to enable tracking of all pregnant women and newborns so as to monitor and ensure that complete services are provided to them. States are encouraged to send beneficiary wise SMS alerts to ANMs on weekly basis and also reminders to beneficiaries reminding them of the dates on which services are due.

### Integrated Child Development Services Scheme

Integrated Child Development Services is a centrally sponsored scheme aimed at holistic development of children below 6 years of age and pregnant women and lactating mothers by providing a package of six services comprising of (a) supplementary nutrition; (b) preschool nonformal education; (c) nutrition and health education; (d) immunization; (e) health checkup; and (f) referral services through *Anganwadi* center at grassroots level.

In India, the achievements as per the MDGs vary for different indicators. For some of the indicators, India has achieved the targets ahead of the time line, like indicator 1A, i.e., halving the percentage of population below the poverty line. Targets 1, 3, 4, 7 and 18 are on track, while targets 5, 8 and 9 are moderately on track, targets 2 and 6 are off track. Target 10 is on track for drinking water and off track for sanitation. The trend reversal types of targets (targets 7 and 8) have been realized in India, as India have successfully halted and reversed the spread of HIV/AIDS and malaria and tuberculosis.

The ultimate responsibility to achieve the MDGs, to monitor and report on progress, lies with the Government of India.

Effective leadership and appropriate stewardship of national and international resources for development, in general, and health development, in particular, are the keys for achieving the MDGs. There is need for strengthening health systems and scaling up of all the programs at all levels at a priority level to achieve MDGs.

## Chapter 1.5

# Evidence-based Care in Pediatrics

Joseph L Mathew

The term *evidence-based medicine* (EBM) has become a buzz phrase in recent decades. It is heard in all scientific deliberations in health care. Although it is not universally accepted, resistance to this form of clinical practice is gradually diminishing. The scope of EBM has been broadened with terms like *evidence-based practice* and *evidence-based health care*. Some experts prefer to use the more neutral phrase *evidence-informed* rather than *evidence-based* as it signifies that evidence has been considered in the decision-making process, though not necessarily applied. Whatever term is used, broadly it refers to the scientific discipline of incorporating research and clinical evidence into health-care decisions and practice. In this sense, evidence-based pediatrics is not different from other forms of evidence-based health care.

### WHAT IS EVIDENCE-BASED HEALTH CARE?

Excerpts from some of the definitions for EBM proposed by various experts during the evolution of EBM, help to clarify the concept and (perhaps more important the) scope of EBM (**Table 1**). For want of a more specific definition, *evidence-based pediatric care* can be taken to include the principles, processes and practice of EBM (as highlighted in **Table 1**) for the health and well-being of children.

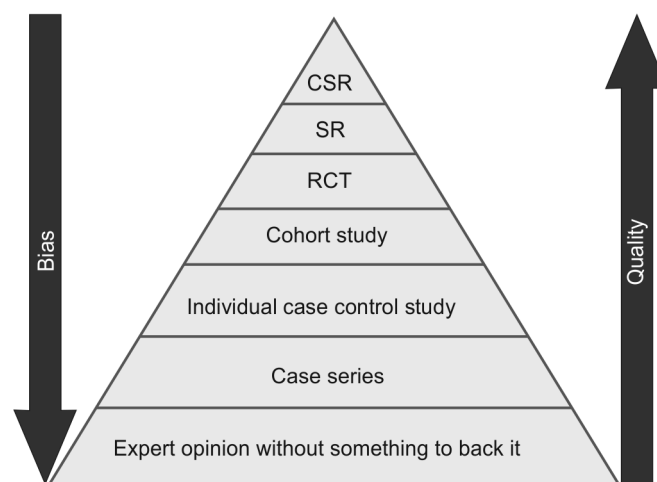

**Table 1** Excerpts from definitions of evidence-based medicine

1996	"conscientious, explicit and judicious use of current best evidence in making decisions about the care of individual patient" (Sackett, et al. BMJ. 1996; 312:71-2)
1998	"integration of good evidence with clinical expertise and patient values" (Straus and Sackett. BMJ. 1998;317:339-42)
2002	"to encourage practitioners and patients to pay due respect—no more, no less—to current best evidence in making decisions" (Haynes, et al. BMJ. 2002;324:1350)
2003	"Integrating clinical expertise with best available external evidence in the care of the individual patients keeping in mind the patient's circumstances" (Sehon and Stanley. BMC. 2003;3:14)
2005	"way of thinking arguing that health care decisions need to be focused on research-based evidence" (De Backer, Verh K. Acad Belg. 2005;67:205-17).

It is perhaps relevant at this point to also understand what is not *evidence-based care*. Applying the results or conclusion section of one or more research papers in clinical practice; or seeking or identifying research papers that support or justify whatever a professional is doing; do not constitute evidence-based care. Other misconceptions about EBM are that its purpose is to make practice of health care more *democratic*, in the sense that, professionals with and without vast experience are at the same level of subservience to research evidence. Some professionals mistakenly also believe that its main application is to judge whether interventions that work in developed country settings can be applied to local settings; while others feel that *evidence-based care* reduces the need for clinical judgment as all children with a given clinical condition could be treated with a uniform protocol.

Strictly speaking, the term *evidence-based* may be a misnomer because it implies that there is a scope for *non-evidence-based practice* as well. However, in fact almost all health-care professionals use some kind of evidence to base their clinical decisions and it is unlikely that anyone acts solely on personal whims. However, there is a wide latitude in what constitutes *evidence* and even more about what constitutes *best evidence*. All professionals would agree that *evidence* is based on observations in the clinical or research setting, and that greater the number of observations pointing in a given direction, the more likely (though not necessary) that it points toward the *truth*. However, *best evidence* creates controversy. Many professionals argue that their personal experience and observations constitute the best evidence for their patients (and practice setting). However, the traditional evidence hierarchy places *expert opinion* right at the bottom of the pyramid (**Fig. 1**), even below case reports of individual patients. But, the definition of EBM insists that clinical expertise is a significant component! This apparent paradox can be resolved if we understand that *best evidence* is based on efforts to remove or resolve systematic error or bias (defined in simple terms as anything which leads away from the truth) from the observations comprising evidence. In other words, any form of evidence that has a lower risk of bias would climb upwards on the evidence hierarchy and vice versa. This is why randomized controlled trials (RCTs) of interventions and systematic reviews of RCT are ranked highest in the evidence hierarchy.

*Patient values* include the unique circumstances (such as health-care setting, personal or social issues, economic status, etc.) of individual patients for and hopefully by whom health-care decisions are made. In a well-developed health-care system (unlike the provider-driven settings in most developing countries), patients, i.e., consumers of health care are provided the

**Figure 1** The evidence hierarchy

Abbreviations: CSR, Cochrane systematic reviews; SR, systematic reviews; RCT, randomized controlled trial

professional's judgment (based on clinical expertise) and the best evidence (based on relevant research and the experience in that health-care setting); and they are encouraged to make decisions factoring-in their perception, situation and expectations. The role of the professional is to facilitate this process and guide patients in the right direction. Ideally, this is how evidence-based care is to be practiced. Therefore, it may happen that while professional judgment and research evidence point to a certain direction, the patient chooses not to take that direction on account of his or

her values. When such a decision is a shared process between the patient and the professional then it too constitutes *evidence-informed practice*.

## EVIDENCE-BASED PRACTICE

A detailed description of how to practice evidence-based health care is outside the scope of this chapter. Readers are referred to access “More on this Topic” given at the end of this chapter for excellent summaries and freely available online resources. A brief outline of the steps involved in evidence-based practice is presented in **Table 2**.

It should be clearly recognized that evidence is a tool to facilitate appropriate decision-making and is not the decision itself. A parallel can be drawn from the various laboratory tests ordered by professionals. Good physicians use the results of laboratory tests to confirm what they suspect on the basis of their knowledge and clinical expertise. They also factor in the circumstances of an individual patient and the local health-care setting. They would not base their decision(s) solely on the basis of the test results no matter how impressive they appear to be. This is how evidence is expected to be used in the real world. In contrast, some physicians order a battery of laboratory tests without clinical justification; and then proceed to treat the abnormal results irrespective of their (ir)relevance. There are some who practice EBM in a similar inappropriate fashion.

## Quality of Evidence

Evidence used for decision-making needs to be critically appraised for quality which determines its internal and external validity. Quality usually refers to two different aspects, viz. *methodological quality* (related to the study design) and *process quality* (related to the process of generating the evidence). The former includes methodological refinements in research studies that are designed to reduce bias, for example, randomization and allocation concealment to minimize selection bias, intention-to-treat analysis to mitigate attrition bias, etc. The latter includes procedures to minimize errors in data collection, for example, averaging of multiple measurements, instrument calibration, using gold standard tests or methods, etc. There are various tools available for appraising primary and secondary research for *methodological quality*, whereas the judgment of *process quality* is often left to the discretion of researchers, or journal editors or the peer review process.

Recognizing the need to support health-care professionals in using evidence as a tool in pediatric practice, “*Indian Pediatrics*” initiated the EURECA [Evidence that is Understandable, Relevant, Extendible (to the local setting), Current and Appraised critically] section some years back. The idea was to provide high quality evidence in an easy to understand format, on various aspects of child health, facilitating pediatricians in the country and region, to make informed decisions (Mathew. *Indian Pediatr.* 2008;45:95-8).

However, evidence-informed pediatric practice involves much more than accessing, appraising and applying the relevant evidence. It involves a careful appraisal of additional issues such as financial costs, cost-effectiveness of interventions, social implications, feasibility, logistics, long-term impact, etc. These components together form the discipline of health technology assessment (HTA). Most developed health-care systems rely on information provided by HTA organizations to guide their decision-making system. In contrast, many developing health-care systems lack such facilities and experience challenges in making rational decisions at the individual, institutional, organizational, or national level.

## CHALLENGES TO EVIDENCE-BASED PEDIATRICS PRACTICE

Health-care professionals expect research evidence to provide answers to their decision-making questions, such as “Should I use this medicine or vaccine or test or procedure?” However, research evidence is designed to address specific clinical questions [in the famous PICO format (identify the patient problem or population (P), intervention (I), comparison (C) and outcome (s) (O))] from which individual stakeholders (professionals, patients and health-care systems at large) are expected to derive conclusions and then make their decisions. Thus evidence cannot dictate what a professional should do. It is designed to provide information on the basis of which, the professional and patient together have to make a shared decision, incorporating clinical experience and personal values, respectively. This requires knowledge and skills to understand, interpret and apply research evidence. This is the art of practicing the science of EBM.

Often, health-care professionals appreciate the value of incorporating evidence in their decision-making processes, but the evidence is either unavailable or inaccessible (at the time or place required). This is largely related to the health-care setting wherein crowded clinics or wards and limited technological facilities, pose challenges to the real time access and application of research evidence. This situation has undergone tremendous improvement with the availability of mobile phone based applications and better internet connectivity at the point of care.

Even when evidence is available, there are challenges to applying it. Some of these are related to the evidence itself. Of more than 140 Cochrane reviews related to the field of *pediatric pulmonology*, 30% were not applicable in India simply because the intervention is either not available, or not accessible, or not affordable, or not acceptable. About 35% reviews do not offer definite conclusions and hence cannot be applied. Only one-third (35%) reviews have conclusions that have the potential to be applied in the Indian context (Mathew, 2006). The other major limiting issue in evidence-based practice is the generalizability of evidence. As for many issues in health-care, evidence generated from a particular setting may not be directly applicable to other settings. This could be on account of biological characteristics of the patient (population) or disease, health-care system differences, locally relevant guidelines, or even cultural practices or traditions. Some of these limitations may operate even when evidence is generated from the same or similar setting. For example, evidence on milder forms of disease cannot be extrapolated to patients with severe disease, or those with comorbidities, etc. In such situations, professional judgment is required to determine applicability of evidence, i.e., can the evidence be implemented in my setting? If yes, would it result in similar effects?

Sometimes, all the available evidence does not point in the same direction. Recently an interesting situation arose with the clinically important question of whether daily treatment (compared to intermittent treatment) is appropriate for children with tuberculosis. A systematic review published in 2010 (Menon et al. *Indian Pediatr.* 47:67-73) suggested that daily treatment is superior, based on which the World Health Organization altered its recommendations to favor daily therapy against its previous leaning towards intermittent therapy. A recent Cochrane review (Bose et al., Cochrane 2014), analyzing the same trials and data, reported the absence of any difference between the two treatment regimens, supporting the view that intermittent therapy is as efficacious as daily treatment. The authors explained the difference on the basis of methodological errors in the older

**Table 2** Steps in evidence-based practice

No.	Steps	Remarks
1	Identify an area in your health-care practice where there is uncertainty about what should/could be done for a particular patient or problem.	In general, a common starting point for EBM or EBP is an encounter with a patient, and the need for answers for that particular patient.
2	Frame an answerable question by converting decision questions into clinical questions, using the PICOT format. P = Population/ Patient/ Problem I = Intervention or Exposure C = Comparison O = Outcome(s) of interest T = Time-frame over which outcomes are considered	<p>Exposure is a better term because it encompasses interventions, diagnostic tests, risk factors, prognostic factors, etc., and is applicable to any study design.</p> <p>Outcomes could be hard outcomes such as mortality, cure, etc.; or soft/surrogate outcomes which are indirect markers believed to reflect the hard outcome(s). These are more plentiful but less robust. When in doubt, opt for patient-centric outcomes, i.e., which are relevant to patients.</p> <p>Time-frame is often not included, but it could be important because certain outcomes develop over time, (and although important may not be captured adequately in a research study) while others occur in the short-term and are easier to record.</p> <p>Some experts add an additional component called Study design (S), which gives the option of focusing the clinical question to specific designs. For example, efficacy of interventions is best answered through randomized trials, but this may not be the ideal design to capture rare adverse events.</p>
3	Search and collate literature to access and identify best evidence addressing the clinical question.	<p>Literature search could be broad-based (sensitive) or focused (specific).</p> <p>Some of the tips and tricks to refine literature searches include: (i) choosing appropriate search terms with the aid of MeSH terms, (ii) starting with a highly sensitive search and narrowing down to a more specific search, (iii) using multiple databases that include the Cochrane Library (free access within India), Medline through PubMed, and subject specific databases, (iv) using Filters/Limits to increase specificity, and (v) recording the output carefully.</p> <p>It is important to target high quality evidence in literature search. Hence one could restrict the search to specific study designs associated with low(er) risk of bias, or look for systematic reviews of such studies.</p>
4	Critically appraise the literature	<p>There are numerous tools that facilitate a rapid and fairly easy appraisal of Methodological quality. Most of these are available online and reflect: (i) whether the study included methodological refinements limiting bias, thereby assessing validity, (ii) the main results and whether these are both statistically as well as clinically significant; and (iii) if yes, whether the results could be applied to the individual patient in the real-life setting.</p> <p>Process quality requires some understanding of the subject area, in order to judge whether the procedures described in the research evidence, are valid (or not).</p>
5	Synthesize the best evidence	<p>For <i>users</i>, i.e., those who would use the evidence, such a synthesis would be available through a systematic review. For <i>doers</i>, i.e., those who would generate the best evidence, the synthesis is under the umbrella of a systematic review (with or without meta-analysis).</p> <p>If systematic reviews are not available, synthesis involves carefully extracting data from individual pieces of evidence and putting it together.</p>
6	Interpret the evidence	Interpretation of evidence requires basic knowledge and skill in the subject area, research methodology, and biostatistics. Although an in-depth knowledge may not be required, broad understanding is required to interpret the evidence as opposed to blindly believing the authors' conclusions.
7	Consider applying the evidence based on your clinical expertise and a shared understanding of the patient's values	<p>Before attempting to apply the evidence, a free and frank discussion with the patient (and especially family where children are involved) is required to explain the information gained through your clinical expertise and the current best evidence.</p> <p>This has to be put together with the patient (family) preferences, beliefs, perceptions apprehensions, concerns, desires, financial status, logistic considerations, etc. The evidence should be applied only after a mutually acceptable shared decision is reached jointly by the health-care provider and recipient.</p>
8	Assess the results	<p>Evaluate the results whether or not the intervention was applied.</p> <p>Ensure that patients (families) are participant to the evaluation process.</p>

review. Clearly the WHO had failed to recognize this when it framed its guidance. Such situations can confuse potential users of evidence and drive them away to more traditional formats of decision-making.

### Efficacy versus Effectiveness

Research evidence usually presents information of the *efficacy* (and sometimes) safety of interventions from research settings, whereas in real-life, we require information on *effectiveness*. In simple terms, efficacy addresses the issue “Does this work in a highly controlled research setting?” whereas effectiveness reflects “Will this work in the real-world health-care setting?” Assessment of effectiveness requires a careful appraisal of issues beyond efficacy and safety, and encompasses aspects like the health-care setting, feasibility, logistics and cost considerations of the intervention (and its alternatives), social aspects and other issues.

It should also be recognized that *health-care interventions* (therapeutic/diagnostic) rather than *health problems* are the usual starting point for generating primary and secondary research evidence. Therefore, practice of EBM can become a process of applying interventions that are supported by evidence, at the cost of ignoring other options for which robust evidence on efficacy may not be readily available. For example, research evidence may suggest that a particular vaccine is efficacious in a given setting, but there may not be sufficient evidence on alternate measures to tackle the health-care problem (through better sanitation, hygiene, and nutrition). In such a situation, implementation of the efficacious intervention gives the impression of evidence-based practice.

### Tertiary Research

The complexity involved with understanding, interpreting and thereafter applying research evidence has spawned a new brand of analysis referred to as *tertiary research* (for want of a better term). This form of research has become critical for health-care stakeholders (professionals, patients, policy-makers, advocacy groups, lay press, etc.) to cut through the technical jargon in research, identify the relevant message and provide a summary that can serve as a tool for evidence-based decisions. In that sense, it demands a very high level of skill and integrity from the tertiary researcher. The former, because it is more complicated than generating primary or secondary evidence and leaving the stakeholder to interpret the same. The latter because the tertiary researcher can consciously or unconsciously mislead the stakeholder in the direction of his/her own bias(es). Unfortunately, although a lot of tertiary research products are in circulation (commentaries, evidence-based editorials, evidence summaries, non-systematically generated guidelines/recommendations, etc.) which are appealing to the end-user, the methodological process for validation of such research is still under development.

### Conflict of Interest

As with all aspects of life, conflicts of interest appear in health-care practice also. It was hoped that generation and application of high quality scientific evidence could reduce some of the biased decisions associated with various conflicts of interest. In this context, evidence has been a two-edged sword in the battle to minimize bias arising from industry pressure. On the one hand, robust evidence has been crucial in facilitating appropriate decisions. On the other hand, industry sponsored research has led to a plethora of high quality (primary and even secondary) evidence from which it is difficult to sift the relevant information. In the context of developing health-care systems, the influence of industry on professional decision-making without accessing the evidence, cannot be over-emphasized.

## WHAT IS THE WAY FORWARD?

Clearly, the way forward to develop a system of evidence-based practice of pediatrics revolves around empowerment. Empowerment is a broad term that encompasses multiple facets and multiple stakeholders. On the one hand, we need to empower health-care providers and health-care consumers to contribute together to generate high quality evidence. This includes research evidence (through well designed studies, systematic reviews and even tertiary research) as well as clinical evidence (through meticulous documentation of observations, peer review, external validation, etc.). This in turn requires developing a pool of people with the requisite knowledge and skills who in turn can become the nucleus for building up (and sustaining) the effort. Such efforts have been made in recent years through the activities of the South Asian Cochrane Network and Center which are bearing fruit. In addition, similar efforts at empowerment have been made through the SIGNET (Singapore Indian Group Networking for Empowerment Training) program and also the Advanced Center for Evidence-Based Child Health (both based at Chandigarh), the excellent paper writing workshops conducted under the aegis of “*Indian Pediatrics*” and various other institutional, organizational and national efforts. Nevertheless, currently these efforts are mostly provider driven rather than demand driven. It is believed that a demand-driven approach can be boosted through introduction of principles of EBM at the undergraduate training level (for all categories of health-care professionals associated with child health).

Further, while these efforts have been successful in enlarging the pool of *doers* who generate primary and secondary evidence, it is unclear whether there is a concomitant pool of empowered *users*. Ideally, empowerment efforts should focus on both users (who would demand appropriate evidence on locally relevant issues) and doers who could fulfill the demand. In the context of evidence-based health-care, the list of users extends far beyond health-care professionals and encompasses virtually everyone who participates in decisions affecting children. This includes policy-makers, organizational leaders, health-care institutions, lay press, and of course the general public. Evidence-based pediatrics practice would take off in the real sense only when all these stakeholders are empowered enough to demand evidence-based practice, interpret its tools, and judge its application.

# PART II Basic Sciences as Applied to Pediatrics

## Section 2 GENETICS AND GENETIC DISORDERS

Section Editor Shubha R Phadke

### Chapter 2.1

### Gene, Genome and Genetic Basis of Diseases

Girisha KM

Genetic constitution of an individual has direct bearing on health and disease. The genetic information is contained in the chromosomes inside the nucleus and a fraction in mitochondria, together referred to as the genome. Some use the words *nuclear genome* and *mitochondrial genome* to separate these entities. This information forms the basis of inheritance of *characters* or *phenotypes* from one generation to the other during reproduction (meiosis) and it is copied to the daughter cells during growth of an organism (mitosis). For the comprehension of human health and diseases, understanding of the structure, function, regulation and variations in deoxyribonucleic acid (DNA) is essential. This chapter discusses the molecular basis of inheritance, gives insight into genetic variations among individuals and their clinical implications.

#### DEOXYRIBONUCLEIC ACID

Deoxyribonucleic acid is the basic molecule that contains the genetic information. DNA is a long polymer of four different nucleotides. Each nucleotide has a nitrogenous base, a deoxyribose sugar and a phosphate group. Nitrogenous bases are purines: adenine (A) and guanine (G); and pyrimidines: cytosine (C) and thymine (T). Sugar and phosphate molecules form two sides of the ladder that are held by strong phosphodiester bonds. The two strands of the ladder run antiparallel to each other with one strand having the orientation of 5' to 3' direction and the other of 3' to 5' direction (**Fig. 1**). The nitrogenous bases facing inside are held by weak hydrogen bonds which facilitate the separation during replication and transcription. Nearly 2 meters of DNA is condensed about 10,000 times and packaged into 46 chromosomes in human nucleated cells. The DNA is first wound around a histone protein core to form a nucleosome, which in turn forms a helical solenoid. The solenoids are then arranged into chromatin loops, which are attached to a protein scaffold and further packaged into chromosomes. Ribonucleic acid (RNA) differs from DNA in having a ribose sugar in place of deoxyribose, and a pyrimidine uracil (U) in place of thymine and is single stranded.

#### DNA Replication

Transmission of genetic information from parent cell to its progeny occurs by replication of DNA. The DNA replication is a crucial

**Figure 1** Illustration of DNA double helix. The two strands of sugar-phosphate backbone run in opposite direction. Strands are held together by hydrogen bonds in between the nitrogenous bases; two hydrogen bonds are formed between adenine (A) and thymine (T) and three hydrogen bonds between guanine (G) and cytosine (C)

event which leads to the formation of two identical copies of the original DNA that get segregated into two daughter cells during cell division. The replication begins with uncoiling and separation of two strands of the DNA molecule by the enzyme helicase. Each strand of the DNA guides the synthesis of its complementary copy through complementary base pairing. Adenine pairs with thymine and cytosine pairs with guanine resulting in formation of two DNA molecules identical to the original parent molecule. This process conserves the genetic information, and transmits it unchanged to each daughter cell and hence called semiconservative synthesis. The vital enzyme in the course of DNA synthesis is DNA polymerase. The synthesis of new DNA strand proceeds in 5' to 3' direction during the S (synthetic) phase of the cell cycle. This process initiates at several sites concurrently. This leads to formation of one continuous strand named leading strand which is the copy of the 3' to 5' strand; and the other strand named lagging strand is synthesized in parts. These parts are called Okazaki fragments which are later joined together by the enzyme DNA ligase.

#### Transcription

Transcription leads to formation of RNA from DNA which then migrates to cytoplasm for synthesis of proteins (**Fig. 2**). The

**Figure 2** The process of transcription starts with the synthesis of single strand of RNA using double-stranded DNA as template by the enzyme RNA polymerase II. The two strands of the DNA molecule are separated from one another, exposing the nitrogenous bases and the antisense strand or template strand is actively transcribed. The RNA produced is known as primary RNA transcript which undergoes RNA splicing. During the splicing event, the introns (blue) are removed and the exons (black) are joined together to produce mature mRNA

product of transcription is called a transcript. The transcript of the coding DNA is known as messenger RNA (mRNA). The mRNA is synthesized by the enzyme RNA polymerase that adds complementary ribonucleotides to the RNA chain. Thymine is replaced by uracil in the mRNA. The particular strand of DNA that acts as a template for synthesis of mRNA is called *antisense strand* so that the new molecule of mRNA is the copy of the other *sense strand*.

The mRNA thus formed is further processed by removal of introns at specific splice sites, addition of a methylated guanine nucleotide to the 5' end of the molecule (5' capping) and addition of about 200 adenylate residues at the 3' end (polyadenylation). The mRNA leaves the nucleus to cytoplasm after several processing events and is then translated into a polypeptide chain or a protein.

### THE GENETIC CODE: HOW DO THE GENES CODE FOR PROTEINS?

There are 20 different amino acids which are the basic units of protein. The sequence of triplet nucleotide bases in the DNA molecule that specifies the sequence of amino acids in the protein molecule is called the genetic code (**Fig. 3**). After transcription, the codons on mRNA are non-overlapping, and are read as per translational reading frame. Among 64 possible triplet codons from four nucleotides, more than one codon code for same amino acid (called degeneracy, since there are only 20 amino acids). Three codons terminate polypeptide chain synthesis (stop codons). The genetic code from DNA is transmitted to codons of the mRNA during transcription which is then decoded into specific amino acids during translation.

### Translation

The codons of mRNA direct the synthesis of a polypeptide chain by incorporating specific amino acids during the process of translation. In the ribosomes, the site of protein synthesis, the processed transcript molecules with the help of specific transfer RNAs (tRNA) carrying the *anticodons* for individual amino acids synthesize the polypeptide chain. The polypeptide chains undergo several post-translational modifications (hydroxylation, methylation, glycosylation, proteolytic cleavage, etc.) to become functional proteins that are transported to their specific cellular locations. The process of transfer of genetic information from DNA to RNA to protein is sometimes referred to as *central dogma* of molecular biology (**Fig. 4**).

	U	C	A	G	
U	Phe Phe Leu Leu	Ser Ser Ser Ser	Tyr Tyr STOP STOP	Cys Cys STOP Trp	U C A G
C	Leu Leu Leu Leu	Pro Pro Pro Pro	His His Gln Gln	Arg Arg Arg Arg	U C A G
A	Ile Ile Ile Met	Thr Thr Thr Thr	Asn Asn Lys Lys	Ser Ser Arg Arg	U C A G
G	Val Val Val Val	Ala Ala Ala Ala	Asp Asp Glu Glu	Gly Gly Gly Gly	U C A G

**Figure 3** The genetic codes from DNA are transcribed to codons in mRNA. Three nucleotides (triplet) code for an amino acid. The codes are degenerate (each amino acid is coded by more than one codon). Three stop codons terminate the polypeptide chain synthesis

**Figure 4** Central dogma of molecular biology: Flow of genetic information from DNA to RNA to protein. Replication: a double-stranded nucleic acid is duplicated to give identical copies which are equally distributed to both the daughter cells. Transcription: Gene, a DNA segment, is transcribed into a single-stranded sequence of RNA which then moves from nucleus to cytoplasm. Translation: In the cytoplasm, the RNA sequence is translated into a sequence of amino acids as the protein by ribosomes and tRNA

### Gene

A *gene* may be conceptualized as the stretch of DNA that contains the information required for a functional product. The product encoded may be a polypeptide or an RNA molecule. It was thought

**Figure 5** Simplified overview of structure of a gene: A typical protein-coding gene is made up of a promoter (facilitates the binding of RNA polymerase to the gene during transcription), a transcriptional start site (contains the initiation codon ATG), exons (encode the information for a functional protein), introns and the 5' and 3' untranslated sequences (play a role in gene regulation). Other regulatory elements may be near or far away from these sequences

that the coding sequence of a gene lies in continuity, which is now known to be a rarity. Now, the *gene* has been shown to consist of amino acid coding exons, intervening noncoding introns, promoter sequences at 5' region that initiate transcription, 3' sequences that give stability to mRNA molecule in the cytoplasm and other regulatory elements like enhancers, silencers, and locus control regions (**Fig. 5**). Genes may overlap, may be found within another gene, or even the same sequence may be transcribed in reverse direction to produce another product.

### Regulation of Gene Expression

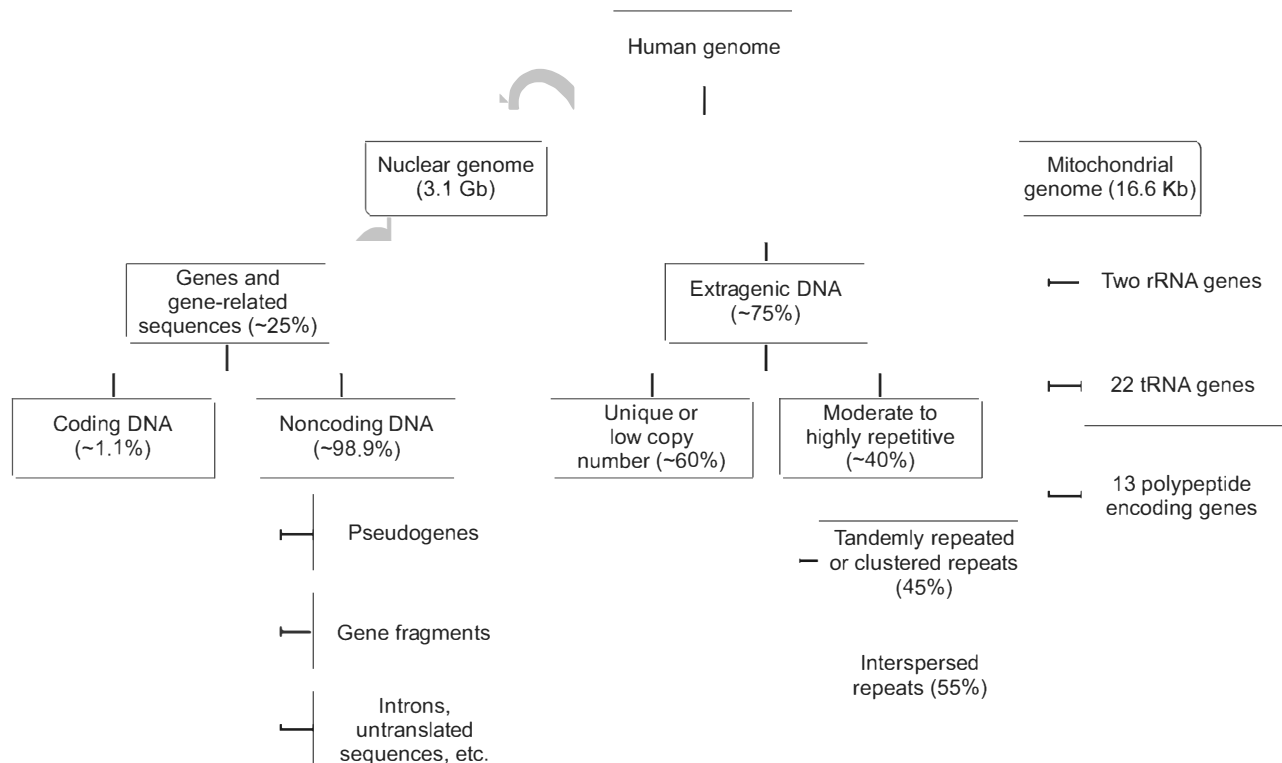

The genes in each human cell control all the cellular processes and maintain homeostasis. Their expression varies at different stages of development, and depends on the cell/tissue type. Several complex pathways are involved in controlling the temporal and spatial expressions of genes. Gene expression may be regulated via signaling molecules that bind to regulatory

sequences of DNA (transcription factors), nuclear receptors (hormones) or even specific ligands located at the cell surface for signal transduction. The transcription factors may bind to promoter elements (TATA, GC and CAAT boxes) of the specific genes located adjacent to the coding region (cis-acting) to regulate the pace of protein synthesis, or to enhancer or silencer elements located at a distance and act on both copies of the gene (trans-acting) to enhance or suppress the transcription. Transcription factors themselves are coded by genes and bind to DNA to regulate gene expression. Gene activity may also be related to patterns of chromatin condensation and methylation. Heterochromatin is the part of the DNA which is usually highly condensed and is characterized by histone modification that makes it inaccessible to transcription factors, whereas euchromatin is decondensed and transcriptionally more active. Though regulation of expression of most of the genes is mediated by transcription factors, regulation can also occur at various stages of protein synthesis. Alternative splicing is a mechanism where a gene can code for more than one protein or at varying rates. Some regulatory sequences are now known to harbor mutations, though exact mechanisms of gene regulations are not fully elucidated yet.

### ORGANIZATION OF THE GENOME

The *human genome* refers to the complete set of genetic information in human cells. In other words, genome refers to the entire DNA content of the cell. It comprises two parts: a large nuclear genome ( $3 \times 10^9$  bp) and a very small mitochondrial genome (16.6 kb; **Flow chart 1**). The nuclear genome provides a great bulk of genetic information, most of which specifies synthesis of proteins of the body. Mitochondria possess their own

**Flow chart 1** Organization of human genome

genome which encodes their own tRNA, ribosomal RNA and few of their own polypeptides.

## Nuclear Genes

It is estimated that there are about 22,000 protein coding genes in the entire nuclear genome. The size of the genes vary greatly, with small genes comprising of 1–3 exons (beta globin) and large genes with up to 79 exons (dystrophin gene, ~2.2 Mb).

Unique single-copy genes are present in single copy (in the haploid set of chromosomes and double in the diploid normal human cell). These encode the polypeptides that are involved in a wide variety of cellular functions: enzymes, receptors, regulators and structural proteins. Some others are members of multigene families. These arise through gene duplication events during evolution. These may be found in physically close clusters, like alpha and beta globin genes on chromosome 16 and 11, respectively or dispersed throughout the genome, like the *HOX* gene family, which are important developmental genes. The genes which encode the ribosomal RNAs are clustered as tandem arrays at the short arms of the acrocentric chromosomes and those encoding the tRNAs occur in numerous clusters throughout the genome. These constitute classic gene families. Genes encoding the human leukocyte antigens and the T-cell receptor genes belong to the immunoglobulin gene superfamily. Pseudogenes closely resemble known structural genes but do not have well-known functions. They are thought to have arisen either by duplication of genes that have lost function due to mutations or by insertion of complementary DNA sequences lacking promoter sequences.

## Extragenic DNA

The noncoding regions of human genome (98–99%) are made up of repetitive DNA sequences that are predominantly inactive. These have also been referred to as junk DNA, but have some uncertain regulatory role. Some are tandem repeats of varying lengths of DNA molecule and include satellites and minisatellites. Highly polymorphic short tandem repeats of core units made up of 10–100 base pairs are used in DNA fingerprinting. Microsatellites consist of tandem repeats of 2–4 base pairs sequences located throughout the genome. Some repetitive DNA is interspersed throughout the genome.

## Mitochondrial DNA

Mitochondria contain their own 16.6 kb circular DNA (mtDNA). It encodes for 37 genes including two for ribosomal RNA, 22 for tRNA and 13 for polypeptide sequences. It is important to recognize that most of the protein components of mitochondria are product of nuclear genes and mutations in them are responsible for the so called *mitochondrial diseases* and yet exhibit autosomal inheritance.

## Sequence Variations in Human Genome

Humans display a remarkable degree of genetic variation, mostly in the noncoding regions. The most obvious traits include height, blood pressure and skin color. Variation in disease traits, response to drugs and susceptibility to diseases are also attributable to the genetic variations. Even though the sequence of human nuclear DNA is 99.9% similar between any two individuals, only 0.1% difference is sufficient for no two individuals to be alike.

## MUTATIONS AND POLYMORPHISM

A change in DNA sequence that is heritable is known as mutation. DNA sequences and genes may vary from person-to-person as a

consequence of mutation. *Allele* refers to the different sequences on a particular location (locus) of the chromosome and each individual has two copies of gene and sequences of both the copies of the gene at a given locus may be similar or different (alleles). A homozygous individual has the same allele on both members of a chromosome pair and the alleles differ in a heterozygote. The genotype refers to the alleles present at a given locus. The locus is said to be polymorphic if it has two or more alleles where the frequency of the minor allele exceeds 1% in a population. Usually such alleles do not produce significant phenotypic effect (these are neutral in effect), but are presumed to be selected/maintained in the population. These can serve as useful genetic markers for mapping disease traits. These variations are also responsible for visible variations between two individuals and also for the variability in susceptibility to various common diseases including infectious diseases.

## Mutation Types

The variations in the human genome may occur at the genomic level as in aneuploidy, at chromosomal level as in translocations/inversions/duplications/deletions, or at the gene level as in point mutations or small deletions/duplications. A germline mutation affects cells that produce gametes and is transmitted from parent to offspring and results in inherited/familial genetic conditions, whereas a somatic mutation is confined to somatic cells and is responsible for cancers or somatic mosaicism.

Mutations in individual genes are classified on the basis of sequence change and its consequence on protein product and its function. Substitution refers to replacement of a single nucleotide by another and is the most common type of mutation. Transition refers to substitution of the same type of nucleotide (i.e., purine by purine, or pyrimidine by pyrimidine nucleotide). The reverse is transversion. Substitutions can result in a synonymous change (silent, with same amino acid retained in the protein product), or a nonsynonymous change of amino acid. Nonsynonymous mutations are missense when the altered amino acid affects protein function or stability, and nonsense when it leads to creation of a stop codon and terminates synthesis of polypeptide chain.

Deletions result from loss of one or more nucleotides. If it occurs in the coding sequence, it may disrupt the reading frame (frame shift mutation), unless the deletion affects nucleotides that are a multiple of three (in frame). Larger deletions involving a part or whole of the gene also occur.

Insertion refers to addition of one or more nucleotides into a gene. Depending on the number of nucleotides inserted, the mutation may cause a shift in the reading frame. Expansion of triplet repeats is a form of insertion.

Substitution, insertion and deletion may affect the splice site, either by activating a cryptic splice site or by abolition of a regular splice site. This may result in exon skipping, retention of intronic sequences and frame shift.

Functionally, a mutation can lead to loss of function of a protein (deletion of some exons of dystrophin gene in Duchenne muscular dystrophy), haploinsufficiency (50% of the protein product is insufficient for normal cellular function as in familial hypercholesterolemia) or gain of function (as in achondroplasia), or rarely a dominant-negative effect where product of mutant gene in heterozygous state results in loss of activity of normal gene product of the corresponding allele as well (osteogenesis imperfecta).

It is important to note that about 85% of the disease causing variations are located in the coding regions, rest are spread in the noncoding regions (introns or regulatory regions).

## GENETIC ALTERATIONS IN DISEASE

The above mutations are illustrated by several common genetic conditions. Down syndrome occurs due to an extra copy of chromosome 21 and Turner syndrome due to lack of second sex chromosome. Cri du chat syndrome occurs due to deletion of a small terminal segment of short arm of chromosome 5. DiGeorge syndrome and Williams syndrome are examples of large deletions that are however beyond the resolution of karyotyping. Beta thalassemia is characterized by several point mutations (missense) in beta globin gene whereas alpha thalassemia commonly occurs due to deletion of a large segment of alpha globin gene. Duchenne muscular dystrophy usually results from large deletions (in about 60% of cases) and rarely from large duplications (in about 10%). All cases of sickle cell disease occur due to a single missense mutation in beta globin gene (valine replacing glutamic acid at sixth position of beta globin chain in any population) and two missense mutations account for almost all cases of achondroplasia (G-to-A transition or G-to-C transversion at nucleotide 1,138 of the *FGFR3* gene resulting in glycine to arginine substitution at 380 amino acid). The most common mutation (accounting for a third of all cases) in cystic fibrosis is a deletion involving a codon [three nucleotides, in cystic fibrosis transmembrane conductance regulator (CFTR)]. Fragile X mental retardation has triplet repeat expansion (CGG) in the *FMR1* gene.

It is very pertinent to note the spectrum of genetic defects which are often unique to the disease and sometimes even to the population or ethnicity (delta F508 is common in Caucasians with cystic fibrosis). A genetic disease can be caused by different mutations in the same gene (beta globin in beta thalassemia) or by mutations in several genes (retinitis pigmentosa, hereditary ichthyosis and hereditary hearing loss). Different diseases or phenotypes can be caused by mutations in a single gene (mutations in *FGFR3* cause achondroplasia, hypochondroplasia, Muenke craniosynostosis, thanatophoric dysplasia; mutations in fibrillin 1 cause Marfan syndrome with tall stature and acromicric dysplasia with short stature). Hence, it is vital to understand the genetic basis of every disease to select a suitable diagnostic test. It is equally important to know the implications of a positive and a negative test result.

### Single Nucleotide Polymorphisms

Single nucleotide polymorphisms (SNPs, also pronounced as snips) refer to single base differences in the DNA sequence, found throughout the human genome with a frequency of about 1 per 1000 bp. Each SNP occurs at a frequency of more than 1% of the population. These are mostly biallelic and occur in both coding and noncoding regions of the genome. They can be easily typed and many sites can be assayed simultaneously by automated techniques. Combination of SNPs can be used to construct haplotypes, or SNP profiles which serve as powerful tools to study linkage, genetic predisposition to multifactorial diseases and pharmacogenetics. More recently, SNP microarrays have been extensively used for genome wide association studies and give information on genetic variations across the genome associated with a multifactorial disease.

### Copy Number Variants

Humans have two copies for any particular segment of DNA on two homologous chromosomes. In some areas, the number of copies of a particular segment varies between two human genomes

(of two individuals). This phenomenon is termed copy number variation (CNV) and more of such CNVs are being uncovered by the use of array comparative genomic hybridization which is being widely used for evaluation of children with intellectual disability. A CNV may vary in size from 1 kb to several mega bases and can occur anywhere in the genome. Usually they result from deletion-duplication events and are heritable. It is estimated that approximately 0.4% of the genome of unrelated people typically differs with respect to copy number. Like any other genetic variation, CNVs have been found to be associated with disease susceptibility and resistance. CNVs can result in having either too many or too few of the dosage sensitive genes, which may be responsible for substantial amount of human phenotypic variability, complex behavioral traits, and disease susceptibility. However, they are usually not fully penetrant.

## HUMAN GENOME PROJECT

Completion of the Human Genome Project is a landmark in medical genetics. It began in 1991 and produced the first draft sequence of the human genome by 2001, ahead of its scheduled date of completion. A completed sequence of human genome was unveiled in 2003. The entire data is now available in the public domain. In addition to sequencing of the entire human genome, the project had several other objectives and areas of work as well: human gene maps and mapping of human inherited diseases, maps of model organisms, development of new DNA technologies, and development of bioinformatics, comparative genomics and functional genomics. The project also had an important component to look into various ethical issues arising out of genome research. The project has provided a map of genetic markers using many thousands of polymorphisms (variations) distributed throughout the genome. The information is getting updated regularly and can be easily accessed through the dedicated websites. As a component of the project, several model organisms have been sequenced and their genes show significant homology to genes in humans and provide an opportunity to study candidate genes for human diseases. These model organisms are also invaluable tools to study expression of genes and function of their protein products in normal development as well as their dysfunction in inherited disorders. The newer techniques (next-generation sequencing) have drastically reduced the time to sequence the entire genome of an individual to few weeks and promise to be of great value in diagnosis of genetic diseases in the clinical laboratories. However, knowing the entire genome has significant ethical and social implications in both research and clinical practice as one is likely to receive information that was not sought in the first place.

## THE GENETIC BASIS OF INHERITANCE

The subsequent chapter will deal on modes of inheritance in greater detail. However, it is important to understand that some genes have a large influence on the phenotype and they exhibit monogenic or single gene or Mendelian inheritance. Their effects sometimes can be influenced by modifier genes or environment, which have a very minor effect. Digenic and oligogenic inheritance suggests a large influence of two or a few genes on the phenotype. Polygenic inheritance is said to occur when a finite number of genes contribute additively to the phenotype. When several genetic and environmental factors play a role to cause the disease, it is termed a multifactorial disease. This is exemplified by sickle cell disease

(monogenic), cleft palate and diabetes mellitus (multifactorial) and measles (environmental) where contribution of genes to the disease phenotype gradually declines and that of environmental factors increases. The phenotypes we actually see are a result of complex interplay between several genetic and environmental factors.

## ANALYSIS OF HUMAN GENOME

Analysis of human genome is vital for diagnosis and assessment of predisposition to genetic diseases. This can be done in several ways. The chromosomes can be counted and their large structural variations (more than 5–10 Mb) can be identified by a karyotype. A specific mutation that is known to cause the disease in question can be identified by either sequencing the region of interest or by targeted mutation analysis (using aptly modified polymerase chain reaction or by using the restriction fragment length polymorphism created by the nucleotide variation). Gene/s known to cause a specific disease can be analyzed by sequencing it/them entirely. If the variation involves a deletion or duplication of a larger area, fluorescence in situ hybridization or chromosomal microarray will be useful strategies. Extensive modification of polymerase chain reactions are widely used for laboratory diagnosis of several genetic diseases. Techniques like multiplex ligation dependent probe amplification can be used not only to detect CNVs, but also other changes at the DNA level.

Currently, next-generation sequencing has gained prominence both as a diagnostic tool in the clinic and research tool in identification of novel genes. The selected genes that are sequenced may be incorporated into a gene-panel (for diseases which have same or similar phenotype). The entire coding region (whole exome that is likely to harbor mutations for about 85% of monogenic diseases) or whole genome may also be sequenced by this technology. They will also be cost-efficient soon and are likely to be the first level of diagnostic test for many of the monogenic disorders.

## IN A NUTSHELL

1. DNA is located in the nucleus and is packaged into 46 chromosomes.
2. A very small amount of DNA is located in the mitochondria that the offspring receives from the mother.
3. Only 1.1% of the genome codes (approximately 22,000 genes) for proteins and rest of the genome is noncoding, but may have some unknown/regulatory role.
4. Deoxyribonucleic acid is transcribed to mRNA which is then translated to polypeptides. Polypeptides undergo several modifications to form structural and functional units of the cell.
5. Variations in the DNA sequence are likely to contribute normal variation between two individuals and are termed polymorphisms.
6. Mutations are rare sequence variations and are likely to alter the quantity or quality of the protein that the gene codes for.
7. Monogenic diseases are caused by genes of large effect on the phenotype whereas polygenic and multifactorial diseases have sequence variations in genes with small effect.
8. Phenotypes are influenced by genetic as well as nongenetic (environmental) factors.
9. Recent advances in understanding of human genome and sequencing technologies promise an exciting era of clinical genetics practice applicable to all fields of medicine.

## Chapter 2.2

# Patterns of Inheritance

Prajnya Ranganath, Shubha R Phadke

The gene, the basic molecular and functional unit of heredity, is essentially a sequence of nucleotides within the chromosome. The position of a gene on a chromosome is called a locus and the alternate forms of a gene at a given locus are called *alleles*. Each human somatic cell has a diploid number of chromosomes, i.e., 22 pairs of autosomes and one pair of sex chromosomes. Therefore, every individual has two copies of a gene, one on each of a homologous pair of chromosomes. An individual may be *homozygous* (both copies identical) or *heterozygous* (different alleles on two chromosomes) at any given locus. Of the two alleles of a gene in an individual, the one which is expressed phenotypically is called the *dominant allele*. The *recessive allele* is expressed only when it is present in a homozygous state.

Genetic disorders are conditions that result from mutations in genes, a *mutation* being a random heritable change in the nucleotide sequence of a gene. A genetic disorder that results from mutation in one or both alleles of a single gene is called a *monogenic or single-gene disorder*, while one that results from a combination of multiple genetic and environmental influences is called a *multifactorial disorder*.

Patterns of inheritance were first elucidated by Gregor Mendel, the Austrian monk referred to as the Father of Genetics, through his hybridization experiments on garden peas. He formulated the Mendel's laws of heredity—the law of segregation and the law of independent assortment—based on his observations. Later, with improved understanding of human genetics, it was found that unifactorial inheritance of single-gene disorders follows the same principles outlined by Mendel and unifactorial or monogenic inheritance became synonymous with *Mendelian inheritance*. Mechanisms of inheritance which do not follow the Mendelian principles are referred to as *non-Mendelian types of inheritance*. Patterns of Mendelian inheritance and common non-Mendelian genetic mechanisms are listed in **Table 1**. A good and comprehensive pedigree provides a very good clue to the pattern of inheritance of a genetic disorder in a family.

**Table 1** Mendelian and non-Mendelian patterns of inheritance

## MENDELIAN INHERITANCE

### Autosomal Dominant Inheritance

#### Case 1

P, a 4-year-old female child, was brought for evaluation of generalized tonic-clonic seizures. On examination, she was found to have around ten café-au-lait spots distributed over her trunk and

limbs and Lisch nodules in both eyes. Her father was also found to have multiple café-au-lait spots in addition to multiple cutaneous neurofibromas all over his body, optic gliomas and scoliosis. There was history of similar skin lesions and cutaneous swellings in the paternal grandmother and some more paternal relatives (**Fig. 1**). MRI brain revealed abnormal signal intensities in the basal ganglia and brain stem. A diagnosis of neurofibromatosis type 1 (von Recklinghausen disease) was made and the family was counseled accordingly.

**Figure 1** Pedigree of Case 1 showing affected members in each generation

Neurofibromatosis type 1 is a classic example of an autosomal dominant disorder. As can be seen from the given pedigree, multiple generations of the family are affected, there is a vertical transmission of the condition from one generation to the next and both male and female individuals are affected in the family. Phenotypic manifestations of the disorder are seen even in heterozygous individuals, i.e., with mutation in just one copy of the gene. The chance of an affected parent transmitting the disease-causing mutant allele to each of his/her offspring is 1 in 2 and therefore the risk of recurrence of the condition in each offspring of an affected individual (irrespective of the sex of the transmitting parent or of the offspring) is 50%. The principles of inheritance of autosomal dominant disorders are listed in **Box 1**. Other examples of disorders which show an autosomal dominant pattern of inheritance are achondroplasia, tuberous sclerosis, Marfan syndrome, hereditary spherocytosis and familial hypercholesterolemia.

#### BOX 1 Principles of inheritance of autosomal dominant disorders

- Only one copy of the abnormal gene is required to produce a phenotype
- Affected individual has an affected parent (usually)
- Passed from one generation to the next (vertical transmission)
- Both males and females are equally affected
- Disorder may be transmitted to offspring of either sex
- Risk of recurrence in offspring of an affected individual is 50%.

In the case mentioned here, the child had seizures in addition to café-au-lait spots and Lisch nodules, her father had café-au-lait spots, cutaneous neurofibromas, optic gliomas and scoliosis and her paternal grandmother had café-au-lait spots and cutaneous neurofibromas. Thus, the clinical manifestations of the condition

were variable with a different set of clinical features being seen in each of the affected family members. This variation in clinical features of the same disorder in different affected individuals (sometimes even within members of the same family) is called *variable expressivity*. Another classical example of an autosomal dominant condition which displays marked clinical variability is tuberous sclerosis, wherein manifestations in affected members of even the same family can range from just cutaneous pigmentary lesions (hypomelanotic macules, shagreen patches and facial angiofibromas) with normal intellect to infantile spasms/hypsarrhythmia syndrome and severe intellectual disability. For some autosomal dominant genetic disorders, phenotypic manifestations of the disease may not be seen in some individuals, in spite of them having the disease-causing mutation. This phenomenon is called *reduced penetrance* and it is responsible for the apparent *skipping of a generation* of certain dominant genetic traits or disorders, wherein an individual has an affected parent and an affected offspring, but is phenotypically normal. Penetrance of a genetic disorder is calculated as the proportion of individuals with a disease-causing genetic mutation who express the disease phenotype to the total number of individuals with the mutation. Examples of disorders with reduced penetrance include familial cancer syndromes. Variable expressivity and reduced penetrance are believed to result from the influence of other genetic and environmental factors that modify the phenotypic expression of the primary disease-causing gene mutation.

Like neurofibromatosis type 1, many genetic disorders affect multiple body systems with varied manifestations. This phenomenon wherein a single gene mutation results in multiple phenotypic manifestations involving different body systems is called *pleiotropy* and it is usually due to the involvement of the gene in a common metabolic/signaling pathway(s) present in the different body systems.

In many cases, the disorder may result from a mutation that has occurred newly in the affected individual rather than being inherited from a parent. Such a newly arisen mutation is called a *de novo mutation* and it occurs in the gamete (sperm or egg cell) or just after fertilization. In such cases, the affected individual would have normal parents, normal siblings and no affected relative in the previous generations. However, the risk of recurrence of the disease in his/her offspring would be 50%, as per the principles of autosomal dominant inheritance. Increase in paternal age has been noted to be associated with an increased risk of de novo mutations associated with some autosomal dominant disorders such as neurofibromatosis type 1, achondroplasia, Marfan syndrome and Crouzon syndrome. Increased mutability during spermatogenesis and accumulation of mutations in the sperm cell with age as well as possibility of the mutations conferring a survival advantage to the sperm cells have been postulated as possible mechanisms underlying this phenomenon.

There is another situation where an individual can have an autosomal dominant disorder without the disease being present in either parent or any of the preceding generations. This is a condition called *gonadal or germline mosaicism*, wherein the disease-causing mutation is present in only a proportion of the gonadal cells in a parent. As the mutation is not present in the somatic cells of the parent, the parent will be clinically normal and his/her blood DNA will also test negative for the mutation. If the egg or sperm cell is derived from the mutation-bearing gonadal precursor cell, the zygote and the resultant offspring will be affected with the disease. Gonadal mosaicism is difficult to demonstrate because only some of the germ cells in the parent carry the mutation and it is inferred when more than one offspring is born with an autosomal dominant disorder, in spite of both parents and previous generations being

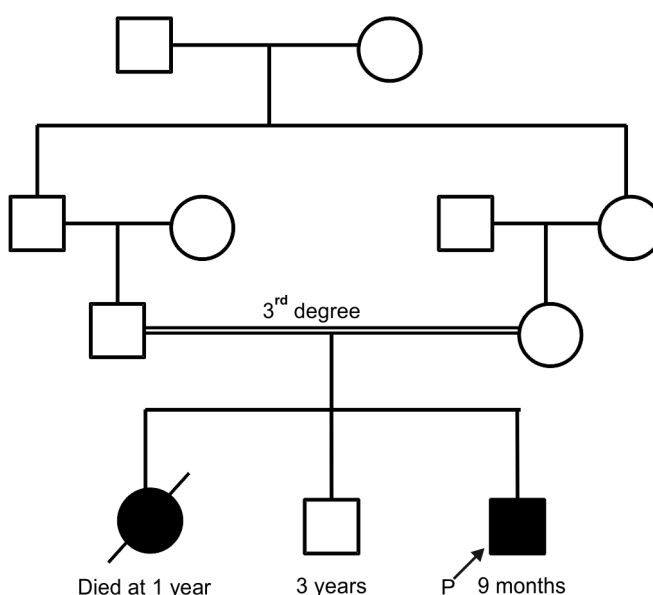

normal (as the same mutation cannot occur de novo in two or more offspring). The phenomenon of gonadal mosaicism should always be borne in mind while counseling a normal couple with one affected child, about the recurrence risk in future offspring; one might assume that the affected child has a de novo mutation as there are no other affected members in the family and give a negligible risk of recurrence, while in fact it might be a case of gonadal mosaicism with a significant recurrence risk. Exact recurrence risks cannot be usually predicted for cases with germline mosaicism, but empiric risks can be derived for each disorder based on previous case reports.

Sometimes, both alleles of a gene may be dominant and may get phenotypically expressed as with the AB blood group; this is referred to as *co-dominance*. The molecular mechanisms underlying autosomal dominant disorders include haploinsufficiency (wherein the protein function is dosage dependent and disease occurs because the mutation reduces the amount of functional protein to half of the normal amount, e.g., Marfan syndrome), dominant negative effect (wherein the mutant allele product interferes with the function of the normal allele product, e.g., some forms of osteogenesis imperfecta caused by mutations in *COL1A1* or *COL1A2* genes) and gain of function (mutation leads to increase of protein function or imparts a new function to the protein product, e.g., achondroplasia).

## Autosomal Recessive Inheritance

### Case 2

R, a 9-month-old male infant, was brought for evaluation of severe chronic anemia with hepatosplenomegaly. He had received a blood transfusion at 6 months of age. He was the third offspring of third degree consanguineous parents and his elder sister had died at 1 year of age due to severe anemia (Fig. 2). His hemogram showed severe microcytic, hypochromic anemia (hemoglobin of 4 g/dL) and hemoglobin electrophoresis revealed markedly elevated fetal hemoglobin (95.7%). Hemoglobin electrophoresis of both parents showed elevated hemoglobin A<sub>2</sub> (>3.5%) suggesting  $\beta$ -thalassemia carrier status. A diagnosis of  $\beta$ -thalassemia major was made and the parents were counseled accordingly.

**Figure 2** Pedigree of Case 2 characteristic of autosomal recessive inheritance

Beta-thalassemia major, one of the most common genetic disorders in India, is an autosomal recessive disorder. As in the given case scenario, one or more individuals in the same generation are affected, while members of previous generations are usually clinically normal. Phenotypic manifestations of the disease are seen only in individuals with mutations in both copies of the disease-associated gene. If mutations in both alleles of the gene are identical, the individual is said to be *homozygous*, whereas if the two mutations (one on each allele of the gene) are different, the individual is said to be *compound heterozygous*. Parents of affected individuals, though usually asymptomatic, are obligate carriers, i.e., each of them has one mutant allele and one normal allele. As the chance of each offspring of carrier parents getting both mutations (one from each parent) is 1 in 4, the risk of recurrence of the disorder in siblings of affected individuals (irrespective of the sex) is 25%. If one parent is affected (homozygous or compound heterozygous) and the other is a carrier (heterozygous), the possibility of the offspring getting the affected parent's mutation is 1 and of getting the carrier parent's mutation is 1 in 2. The risk of recurrence of the condition in the offspring in this scenario increases to 50% ( $1 \times \frac{1}{2}$ ). In such cases, the pedigree will look like that of an autosomal dominant disorder and therefore, the phenomenon is referred to as *pseudodominance*.

The principles of autosomal recessive inheritance are enumerated in **Box 2**. Other examples of autosomal recessive disorders include sickle cell anemia, oculocutaneous albinism, most inborn errors of metabolism, spinal muscular atrophy and cystic fibrosis. Most autosomal recessive conditions occur due to the *loss of function* mechanism, i.e., mutations on both alleles of the gene result in significant reduction in the amount or function of the protein product.

#### BOX 2 Principles of inheritance of autosomal recessive disorders

- Both copies of a gene should be mutated to produce disease phenotype
- Parents of an affected individual, though usually asymptomatic, are obligate carriers
- Horizontal pedigree pattern with one or more siblings affected
- Both males and females are equally affected
- Parental consanguinity increases the risk of autosomal recessive disorders in offspring
- Risk of recurrence in siblings is 25%.

Sometimes, mutations in different genes can produce the same phenotype, i.e., the phenotypic manifestations of mutations in Gene A may be the same as those of mutations in Gene B. This phenomenon of more than one gene being associated with the same phenotype is called *locus heterogeneity*. Classic examples of disorders with locus heterogeneity include sensorineural deafness and retinitis pigmentosa. An individual who is a heterozygous carrier of a mutation in two different genes is called a *double heterozygote*. Double heterozygotes for recessive mutations do not manifest the disease even if the mutations are associated with the same phenotype. This explains why sometimes even when both the husband and wife are affected with genetic sensorineural deafness, their offspring may be normal. If the husband has mutations on both alleles of one deafness-associated gene and the wife has mutations on both alleles of a different deafness-associated gene, each offspring will be a double heterozygote (carrier of a mutation on only one allele of each of the two genes) and will therefore be phenotypically normal.

*Consanguinity*, mating between blood relatives, increases the risk of autosomal recessive disorders in the offspring but is not the sole responsible factor. Absence of consanguinity does not rule out the possibility of a condition being autosomal recessive;

likewise, presence of consanguinity does not necessarily imply that the condition has a recessive inheritance. Autosomal recessive disorders, especially those which have a relatively higher carrier frequency in the general population (e.g.,  $\beta$ -thalassemia in India and the Mediterranean countries and cystic fibrosis in Western Europe) are more likely to occur because of a chance mating between two unrelated carriers. However, consanguinity does contribute to a higher incidence of rare autosomal recessive disorders and the risk of autosomal recessive disorders in offspring of consanguineous couples is around one and a half times more than that of nonconsanguineous couples. When the husband and wife are related, the likelihood of both, being carriers of the same gene mutation increases, due to their descent from a common ancestor. Consanguinity is measured by the *coefficient of inbreeding* which is the proportion of loci at which a person is homozygous for an allele from the same ancestral source. Another entity which increases the risk of autosomal recessive disorders is *inbreeding*, wherein individuals from a small population tend to choose their mates from the same population for cultural, geographic or religious reasons.

### X-Linked Inheritance

#### Case 3

S, a 7-year-old male child, presented with a history of difficulty in getting up from sitting and squatting positions and in climbing stairs since 5 years of age. On examination, he was found to have a waddling gait, proximal muscle weakness, positive Gower's sign and bilateral calf muscle hypertrophy. His serum creatine phosphokinase was 4,080 U/L. Parents gave history of similar illness in two maternal uncles both of whom had become wheelchair-bound by around 12–13 years of age and had died at around 18 years and 20 years, respectively (pedigree shown in **Figure 3**). Genetic testing of the Duchenne muscular dystrophy (DMD) gene revealed a deletion mutation and the diagnosis of DMD was confirmed. The parents were counseled accordingly.

**Figure 3** Pedigree of Case 3 showing X-linked inheritance

Duchenne muscular dystrophy is a genetic disorder with an X-linked recessive inheritance pattern. For any X-linked recessive disorder, all male members of the family with the gene mutation are clinically affected, while female members are just carriers of the mutation and are mostly normal or are only mildly affected. This is because males have only one copy of the X-linked gene, i.e., they are *hemizygous*. As is evident from the given pedigree, X-linked recessive disorders show an oblique or *knight's move* transmission

pattern, wherein an affected male in a family is often found to have similarly affected maternal uncles. Male to male transmission does not occur, because the X chromosome in a male is always of maternal origin. All affected males in a family are related through carrier female relatives.

The principles of X-linked recessive inheritance are listed in **Box 3**. Other examples of disorders with X-linked recessive inheritance include hemophilia A, hemophilia B, Hunter syndrome, Fabry disease, and glucose-6-phosphate dehydrogenase deficiency.

Like autosomal dominant conditions, X-linked disorders can also result from de novo mutations; about one third of all DMD cases result from de novo mutations in the *DMD* gene. Gonadal mosaicism is also seen in X-linked disorders. The empiric risk of recurrence of DMD in male siblings of an affected boy due to gonadal mosaicism in the mother is around 15%. All these entities have to be considered when counseling a family about the recurrence risks. If the mother is a carrier for an X-linked recessive mutation, the risk for each of her male offspring being affected would be 50% and the chance of each of her female offspring being a carrier would be 50%. If however, the couple presents with only one affected male child, without a history of any other family member being affected, the recurrence risk in future male offspring can vary from 0% to up to 50%, depending upon whether it is a de novo mutation, a case of gonadal mosaicism or a maternally inherited mutation. If a male individual is affected with an X-linked recessive disorder, all of his daughters will be carriers but none of his sons will be at risk of being affected.

The other set of disorders that occur due to mutations on X-linked genes are the X-linked dominant disorders. Like dominant mutations on autosomal genes, dominant mutations on X-linked genes are also expressed in heterozygotes and therefore heterozygous females as well as hemizygous males are affected. However, due to the phenomenon of *lyonization* (random inactivation of one of the two X chromosomes in each cell in females), females are usually less severely affected than males. Some of the X-linked dominant disorders, such as Rett syndrome and Aicardi syndrome, have very severe manifestations in males leading to death in the antenatal/perinatal period and are compatible with survival only in females; for such disorders the pedigree will show only affected female members with intrauterine demise/stillbirths of male fetuses. An affected father will transmit the disorder to all his daughters but to none of his sons as male to male transmission of X-linked mutations does not occur. An affected mother will transmit the disorder to 50% of her sons and 50% of her daughters. The principles of X-linked dominant inheritance are listed in **Box 3**. Few more examples of X-linked dominant disorders are X-linked hypophosphatemic rickets (vitamin D resistant rickets), incontinentia pigmenti, orofaciocigital syndrome type 1, Goltz syndrome (focal dermal hypoplasia) and Melnick-Needles syndrome.

Several X-linked disorders, such as fragile X syndrome and ornithine transcarbamylase deficiency (a type of urea cycle defect), cannot be strictly categorized as X-linked recessive or dominant conditions, because they have very variable expression in female individuals. Phenotypic expression of X-linked disorders in females may depend upon a number of factors such as skewed X-inactivation (more of either mutation-free or mutation-bearing cells becoming inactivated instead of around 50–50 random inactivation) and somatic mosaicism. These can lead to manifestations of X-linked recessive disorders and suppression of the phenotype of X-linked dominant conditions in females. Therefore, it has been suggested that the terms *recessive* and *dominant* should not be used and all disorders caused by X-linked genes should be said to have *X-linked inheritance*.

### BOX 3 Principles of inheritance of X-linked disorders

- Disease caused by mutation in gene on X chromosome
- No male to male transmission

#### *X-linked recessive*

- Mostly males affected; carrier females are usually normal or only mildly affected
- Affected males in a family are always related to each other through carrier females
- For a carrier mother, risk of male offspring being affected is 50% and chance of female offspring being carrier is 50%
- For an affected father, risk of male offspring being affected is zero and chance of female offspring being carrier is 100%.

#### *X-linked dominant*

- Both males and females are affected but males usually have a more severe phenotype
- Some disorders are perinatally lethal in males and compatible with survival only in females; disease phenotype is seen only in females
- For an affected mother, risk of male offspring being affected is 50% and risk of female offspring being affected is 50%.

## Y-Linked Inheritance

Y-linked disorders would involve genes on the Y chromosome and therefore would affect only males and be transmitted from an affected male individual to all his sons and none of his daughters. Till date, no single-gene disorder has been identified to have Y-linked inheritance. *Hairy ears* and a type of deafness (Y-linked deafness) were believed to be associated with genes on the Y chromosome, but studies disproved this.

Y chromosome microdeletions involving the azoospermia factor regions that result in azoospermia/oligospermia and consequent male infertility show a Y-linked Mendelian inheritance-like pattern. These microdeletions can be transmitted from an affected male to his male offspring, if his sperms are used in assisted reproductive techniques such as intracytoplasmic sperm injection.

## NON-MENDELIAN INHERITANCE

### Trinucleotide Repeat Disorders

*Trinucleotide repeats* are stretches of repeats of three nucleotide sequences (such as CAG or CGG) which are normally present in some genes, within the exon, intron, 5' untranslated region or 3' untranslated region. When there is *repeat expansion*, i.e., increase in the number of repeats beyond the normal stable level or threshold, the disease occurs. There can be further expansion in the number of repeats during gametogenesis resulting in the affected offspring having a larger repeat number compared to the affected transmitting parent. This is why these mutations are called *dynamic mutations*. The increasing number of repeats leads to increasing severity and earlier onset of the disease in successive generations—a phenomenon known as *anticipation*, which is the hallmark of trinucleotide repeat disorders. For some disorders, the number of repeats can increase so much during gametogenesis that the offspring can get a very severe form of the disease, e.g., expansion of the CAG repeats in the Huntington disease (*HD*) gene during male gametogenesis can result in juvenile HD in the offspring of an affected male and expansion of the CTG repeats in the dystrophin myotonia-protein kinase (*DMPK*) gene during female gametogenesis can result in congenital myotonic dystrophy in the offspring of an affected female. **Table 2** lists some of the more common trinucleotide repeat disorders. Disorders are known to occur due to expansion of tetranucleotide repeats (e.g., CCTG repeat expansion in *ZNF9* gene in myotonic dystrophy type 2) and of other complex repeat motifs also.

**Table 2** Trinucleotide repeat disorders

Disorder	Inheritance	Gene	Trinucleotide repeat	Location of repeat
Fragile X mental retardation	X-linked	<i>FMR1</i>	CGG	5' UTR
Myotonic dystrophy	AD	<i>DMPK</i>	CTG	3' UTR
Huntington disease	AD	<i>HD</i>	CAG	Exon
Spinocerebellar ataxia	AD	<i>ATXN1</i> , <i>ATXN2</i> , <i>ATXN3</i> , <i>ATXN7</i> , etc.	CAG	Exon
Friedreich ataxia	AR	<i>FXN</i>	GAA	First intron
Spinobulbar muscular atrophy	X-linked	<i>AR</i>	CAG	Exon

Abbreviations: AD, autosomal dominant; AR, autosomal recessive; UTR, untranslated region.

### Mitochondrial Inheritance

Disorders caused by mutations in genes in the mitochondrial genome show a mitochondrial inheritance pattern. Each cell has a few to several thousand mitochondria within it and each mitochondrion contains dozens of copies of the mitochondrial genome. Each mitochondrial genome is circular, is made up of around 16.5 kb of DNA and has 37 genes within it (of which 22 code for transfer RNAs, 2 code for ribosomal RNAs and 13 code for protein subunits of enzyme complexes of the oxidative phosphorylation system).

Mitochondrial mutations may be inherited or they may be acquired and accumulate during mitotic cell divisions. A given mutation may be present in only some of the mitochondrial genomes within a mitochondrion and in only a proportion of the mitochondria within a cell, leading to a heterogeneous population within an individual, within a tissue, within the same cell and even within the same mitochondrion, a condition referred to as *heteroplasmy*. If the mutation is present in all or at least a majority of the mitochondrial genomes of an individual, the condition is called *homoplasmy*. Expression of a mitochondrial disorder in an individual and in each body tissue occurs only when the number of mutated mitochondrial genomes in that tissue exceeds a baseline, a phenomenon referred to as *threshold expression*. In addition, there is a rapid change in the heteroplasmy levels between generations and a heteroplasmic state produced by new mutations arising in the female germline is usually transient and resolves itself within a few generations; this is attributed to the *mitochondrial genetic bottleneck* hypothesis. As per this hypothesis, only a limited number of mitochondrial DNA (mtDNA) templates are used during gametogenesis and there is several fold amplification of mtDNA copy number accompanying the maturation of the primary to the preovulatory oocyte, reducing the effective number of mtDNAs that contribute to the next generation.

A typical pedigree associated with an inherited mitochondrial disorder is shown in **Figure 4**. As only the egg cell contributes mitochondria to the zygote, the mitochondrial mode of inheritance is strictly maternal and affected males do not pass on the mutation to their offspring. However, the proportion and distribution of abnormal mitochondrial genomes can vary remarkably, resulting in great variability in the clinical severity amongst the affected individuals in a family. The phenomena of heteroplasmy and mitochondrial genetic bottleneck make prediction of disease

**Figure 4** Pedigree of an inherited mitochondrial disorder

severity, counseling for risk of recurrence in offspring/siblings of affected cases and phenotypic prognostication of prenatally detected mitochondrial mutations difficult.

Some disorders caused by mutations in the mitochondrial genome include Leber hereditary optic neuropathy, chronic progressive external ophthalmoplegia, some types of Leigh disease, mitochondrial encephalomyopathy with lactic acidosis and stroke-like episodes syndrome, myoclonic epilepsy with ragged red fibers syndrome, Kearns-Sayre syndrome and neuropathy, ataxia and retinitis pigmentosa syndrome. Mitochondrial diseases usually affect organs with greater energy utilization and with greater rates of oxidative phosphorylation, e.g., muscles, brain, eyes, heart and endocrine organs and possibility of a mitochondrial etiology should be suspected in any multisystemic disorder, especially involving these systems.

### Imprinting Related Disorders

*Genomic imprinting* refers to the differential expression of alleles of certain genes based upon their parental origin. For such genes, only one of the two alleles, either the paternally derived one or the maternally derived one, would be actively expressed, while the other allele would be silenced through epigenetic mechanisms such as methylation. Therefore, a mutation will have phenotypic effects only if it is present on the active allele but not if it is on the silenced allele. For example, if for a given gene the maternally derived allele is imprinted, then a female affected with a disease-causing mutation in that gene will have phenotypic manifestations of the disorder but her offspring who inherit the mutation from her will not be affected. Some disorders associated with imprinted genetic loci are listed in **Table 3**.

### Uniparental Disomy

Normally, of the two homologues of each chromosome in an individual, one is derived from the father and one from the mother. Occasionally, both the chromosomes may be derived from the same parent, a condition referred to as *uniparental disomy*. Further, if both chromosomes are derived from a single chromosome of a parent and are identical it is called *uniparental isodisomy*, and if the two chromosomes are derived from both of the homologous pair of chromosomes of the parent, it is called *uniparental heterodisomy*. Uniparental disomy at an imprinted locus can result in an imprinting-related disorder as mentioned above, as both the chromosomes would be derived from the parent whose allele is silenced. In addition, uniparental isodisomy of a recessive mutation-bearing allele from a carrier parent would result in homozygosity for the mutation and thereby disease in the offspring even when the other parent is not a carrier for a mutation in that gene.

### Mosaicism

The presence of two or more genetically distinct cell lines in an individual, all of which are derived from a single zygote, is referred

**Table 3** Disorders associated with imprinted genetic loci

Disease	Chromosomal locus	Genetic alterations
Prader-Willi syndrome	15q11-q13	<ul style="list-style-type: none"> <li>• Deletion of paternal-origin 15q11-q13</li> <li>• Uniparental disomy of maternal-origin 15q11-q13</li> <li>• Imprinting center mutations</li> </ul>
Angelman syndrome	15q11-q13	<ul style="list-style-type: none"> <li>• Deletion of maternal-origin 15q11-q13</li> <li>• Uniparental disomy of paternal-origin 15q11-q13</li> <li>• Imprinting center mutations</li> <li>• Mutation in the maternal-origin allele of <i>UBE3A</i> gene</li> </ul>
Beckwith-Wiedemann syndrome	11p15.5	<ul style="list-style-type: none"> <li>• Imprinting center mutations</li> <li>• Uniparental disomy of paternal-origin 11p15.5</li> <li>• Deletion of maternal-origin 11p15.5 or duplication of paternal-origin 11p15.5</li> <li>• Mutation in the maternal-origin allele of <i>CDKN1C</i> gene</li> </ul>
Russell-Silver syndrome	7p11.2 and 11p15.5	<ul style="list-style-type: none"> <li>• Imprinting center mutations</li> <li>• Uniparental disomy of maternal-origin 7p11.2</li> <li>• Hypomethylation of imprinting center on paternal origin chromosome 11p15.5</li> </ul>
Pseudohypoparathyroidism type 1	20q13.2	<ul style="list-style-type: none"> <li>• Uniparental disomy of paternal-origin 20q13.2</li> <li>• Imprinting center mutations</li> <li>• Microdeletions near <i>GNAS</i> disrupting methylation</li> <li>• Mutation in the maternal-origin allele of <i>GNAS</i> gene</li> </ul>

to as *mosaicism*. Mosaicism usually results from a postzygotic mutation event, wherein one or more of the early embryonic cells acquire a mutation, which gets passed on to all the subsequent populations of cells derived from that precursor cell. Distribution of genetically distinct cell lines in different body tissues is called *somatic mosaicism*. Disorders with somatic mosaicism may show a mosaic or patchy involvement of tissues, e.g., patches or streaks of skin pigmentation changes, asymmetric overgrowth, focal bony lesions, etc. (**Figs 5A and B**). Tissue biopsy from affected sites will show a greater proportion of cells with the mutation while biopsy from normal appearing sites will have mostly genetically normal cells. An individual with somatic mosaicism will have normal parents. If the mutation is confined to somatic cells and does not affect any gonadal cells, his/her offspring will also be normal. Examples include McCune-Albright syndrome (somatic mosaicism of mutations in the *GNAS* gene) and Proteus syndrome (somatic mosaicism of *AKT1* gene mutations). Proteus syndrome-associated *AKT1* gene mutation can exist only in the somatic

mosaic form because if the mutation were to be present in all the cells of the embryo, it would be lethal.

### Oligogenic Inheritance

While monogenic disorders have been classically described to be caused by mutations within a single gene, of late some so called Mendelian disorders have been found to be caused by simultaneous mutations within two or more loci, a phenomenon referred to as *oligogenic inheritance* (*oligogenic* meaning caused by a few genes). For example, though Bardet-Biedl syndrome has been classically described to have an autosomal recessive inheritance pattern, in some cases it has been found that an individual with mutations in both alleles of the *BBS2* gene may not manifest the disorder unless there is a mutation present in at least one allele of a second gene, i.e., *BBS6*. The different genes involved in oligogenic inheritance are believed to have synergistic/modifier effects on each other. Other disorders reported to have oligogenic inheritance include one type of retinitis pigmentosa

**Figures 5A and B** (A) Large hyperpigmented patch on the abdomen; (B) Focal fibrous dysplasia involving the right pelvis and right femur in a girl with McCune-Albright syndrome

(*ROM1* and *RDS* gene related) and Hirschsprung disease (*RET* gene with other loci).

### Multifactorial Inheritance

Disorders which are caused by a complex interaction of many different genes and environmental influences are called *multifactorial disorders*. Individual alleles involved in the causation of multifactorial disorders may individually follow any of the Mendelian or non-Mendelian inheritance patterns described above, but the disorder per se, which is a composite manifestation of the different alleles, follows a complex inheritance called *multifactorial inheritance*. Multifactorial disorders include congenital malformations, such as neural tube defects, cleft lip, cleft palate and congenital hypertrophic pyloric stenosis, as well as adult onset disorders such as diabetes mellitus and coronary artery disease.

Characteristics of multifactorial inheritance are as follows: (i) the probability of an affected offspring increases with increase in the number of predisposing risk alleles in the parents; (ii) the risk to relatives decreases as the relationship to the index case becomes more distant (therefore first degree relatives have the highest risk); (iii) the recurrence risk is higher when more than one family member is affected; (iv) the risk of recurrence in relations increases with increase in the severity of the disease in the index case; and (v) for a disorder which exhibits a marked difference in incidence with sex, if the less frequently affected sex is affected, the risk of recurrence is higher in members of the more frequently affected sex in the family (e.g., for congenital hypertrophic pyloric stenosis, the incidence is much higher in male infants compared to female infants; therefore, if a female infant is affected in a family, the risk of recurrence of the malformation in males in the family would be much higher).

### CONCLUSION

Thorough understanding of the patterns of inheritance is essential for appropriate genetic counseling of patients and families with genetic disorders. Once the pattern of inheritance is known, one can predict the risk of recurrence of the disorder in offspring, siblings and other relatives of the index case and offer appropriate interventions such as prenatal diagnosis and presymptomatic diagnosis. Knowledge of the inheritance patterns of diseases also helps in identifying their causative genes through techniques like linkage analysis, homozygosity mapping and more recently whole exome/whole genome sequencing. However, while the classical textbook descriptions of Mendelian and non-Mendelian inheritance patterns are still relevant and useful especially in the clinical setting, the strict distinction between monogenic and

multifactorial diseases is gradually getting blurred with elucidation of newer non-Mendelian forms of inheritance and better understanding of modifier genes. Phenomena like oligogenic inheritance, reduced penetrance and variable expressivity suggest that even the so called monogenic disorders are significantly influenced by other genes and environmental factors. As our understanding of molecular mechanisms of genetic diseases improves, conventional concepts about inheritance patterns are likely to significantly change in the future.

### IN A NUTSHELL

1. Mendelian inheritance patterns, i.e., the patterns of inheritance which follow Mendelian laws of heredity, include autosomal dominant, autosomal recessive, X-linked and Y-linked inheritance.
2. Monogenic disorders follow Mendelian patterns of inheritance.
3. Autosomal dominant disorders show vertical transmission, with a 50% risk of recurrence in each offspring of an affected individual.
4. Autosomal recessive disorders have a recurrence risk of 25% in each offspring of carrier parents.
5. X-linked recessive disorders have a recurrence risk of 50% in each male offspring of a carrier mother and do not have male to male transmission.
6. Non-Mendelian mechanisms of inheritance include trinucleotide repeat expansion, mitochondrial inheritance, genomic imprinting, uniparental disomy, mosaicism, oligogenic inheritance and multifactorial inheritance.

## Chapter 2.3

# Clinical Dysmorphology: An Approach to Bedside Diagnosis

Ratna Dua Puri

Every pediatrician at some time or the other is involved in the diagnosis of a child with abnormal physical features. This article deals with the approach to diagnosis of syndromes associated with developmental abnormalities of body structure.

David Smith defined *dysmorphology* in 1966 as a study of abnormality of body structure that originates before birth. Hall BD described this expertise as a clinical skill, an inexpensive visual diagnostic modality that can be acquired by all who so desire. Reardon and Donnai in their review note that no branch of science offers as much opportunity, challenge and excitement as is there in the diagnosis of a rare disorder or a syndrome in clinical genetics. However, it is not a profession of stamp collectors but one that affords affected families with an answer why their child is different, anticipates and treats complications, and prevents recurrence in affected families.

## WHY STRIVE FOR A DYSMORPHOLOGY DIAGNOSIS?

Dysmorphology diagnosis is not for a collection of rare syndromes. There are definite implications for management, anticipation, evaluation and treatment of complications like atlantoaxial dislocation in Larsen syndrome as well as prevention of recurrence in subsequent pregnancies. It also provides answer to the family why their child is different and halts a diagnostic odyssey and frustration of endless consultations with doctors. Advances in technology now allow identification of genes in cohorts of patients with similar phenotypes as well as identification of new syndromes. Understanding of pathogenesis permits better management and research into treatment of rare disorders. As for all other branches of medicine, a definite diagnosis is essential for improved care and counseling of families with a child with dysmorphism.

## APPROACH TO DIAGNOSIS

A multiple malformation syndrome is defined as a recognizable pattern of a combination of major and minor malformations that occurs due to an underlying etiology. There are more than 5,000 entries in the "*London Dysmorphology Database*" (LDDb) and it is impossible to memorize them all. The approach to diagnosis of a child with dysmorphism or congenital anomalies is not different from one in other disciplines of medicine and comprises a good history with a three generation family history, systemic examination combined with good power of observation. Some specific, salient features in history and examination that have dysmorphology diagnostic relevance are noted below.

## History

In addition to the details of the presenting complaints, this should include the timeline of the malformations, natural course, associated behavior phenotypes, progression/regression of symptomatology if any. There are some syndromes where the phenotype evolves with time, e.g., Prader-Willi syndrome, Noonan syndrome, as well as those where it becomes less apparent and photographs at different ages can hence be helpful. A specific

behavior patterns can aid in diagnosis, e.g., hyperphagy in Prader-Willi syndrome, happy phenotype in Angelman syndrome, disturbed sleep patterns in Smith-Magenis syndrome, and over-friendly behavior in Williams syndrome children; being some of the characteristic behaviors.

A three generation family history and consanguinity history are important because if present, inheritance patterns can be ascertained (**Case 1**). Parental ages at conception, teratogen exposure, history of abortions and stillbirth or abnormalities in the fetus in previous conceptions should be noted. History of maternal disorders like diabetes and infections during pregnancy should be taken (**Table 1**). Prenatal ultrasonography records may provide information about abnormal growth pattern, oligoamnios or polyhydramnios. Events at birth, including fetal distress, birthweight, length and head circumference, and neonatal behavior and feeding history should be sought. Details of development history and behavior with formal assessment are very important. A look into the old records, noted findings and treatment as well as anthropometry details with growth charting over time can assist to reach a conclusive diagnosis in some cases.

## Case 1: The Importance of Family History

*A family was referred to the out patient department for evaluation of intellectual disability in three children. The first child, female had mild intellectual disability and she was not dysmorphic on examination. There were no other significant abnormalities on evaluation. She had twin brothers who were hyperactive with intellectual disability. Except for prominent ears, there were no other abnormalities on examination.*

*On further questioning, the mother of the children was slow in her daily tasks and thinking abilities, though she had completed her graduation. Her father too was reported to be slow intellectually, but was employed and never required assistance for daily living. On direct questioning his maternal uncle was not as bright as his peers and other sibling and had no children.*

The pedigree analysis suggests an X-linked semidominant inheritance. The females are relatively mildly affected and the phenomenon of anticipation is apparent. The behavior phenotype, subtle dysmorphism and the inheritance suggests a diagnosis of the commonest X-linked mental retardation syndrome, fragile X mental retardation syndrome. The diagnosis was confirmed by molecular testing.

## Examination

The first important component is to observe the child and his parents to see if the child resembles them or looks different. It is important to do this unobtrusively so as not to discomfort the family. A detailed head to toe physical examination with recognition of facial dysmorphism, congenital anomalies and anthropometric measurements, should be taken. Abnormalities of growth, body proportions, asymmetry also should be looked for. Knowledge of normal and abnormal phenotypic features and their appropriate description is very important as the first step for diagnosis. "*American Journal of Medical Genetics* [2009:149A(1)]" has given standard terminologies used in description of elements of morphology and is very useful in describing dysmorphic features. The issue of the journal is available free online (<http://onlinelibrary.wiley.com/doi/10.1002/ajmg.a.v149a:1/issuetoc>). A keen observation is important to recognize congenital anomalies. Recognize variations present in one of the parents and child as these may be normal variants and not of clinical significance.

Congenital anomalies could be either isolated or in combination (multiple). Amongst *single anomalies*, *malformations* are developmental defects of a body part and occur early in life. They could be major or minor. A *major malformation* is severe and

**Table 1** History: Important points and their significance

	Details of history	Significance
Family history	3 generation family history	Pattern of inheritance can be identified
	Consanguinity	<ul style="list-style-type: none"> <li>Increased risk of malformations</li> <li>Increased risk of autosomal recessive disorders</li> </ul>
	Recurrent abortions, stillbirths	Chromosomal translocation carrier, X-linked dominant disorder with lethality in males, e.g., Rett syndrome
	Parental age	Advanced maternal age—trisomy 21,18,13 Advanced paternal age—Marfan syndrome, Apert syndrome, achondroplasia
Antenatal history	Drugs—anticonvulsants, methotrexate, retinoic acid, periconceptional folic acid	Fetal phenytoin/valproate syndrome
	Maternal illness—diabetes mellitus, phenylketonuria	Infant of diabetic mother, cardiac and other malformations. Congenital phenylketonuria characterized by cardiac anomalies and microcephaly
	Infections—TORCH (toxoplasmosis, other (syphilis), rubella, CMV, HSV)	Congenital rubella syndrome, etc.
	Abnormal screening test— ↑ AFP ↓ E3 ↑ hCG	Neural tube defect Smith-Lemli-Opitz syndrome Down syndrome
	Abnormal Ultrasound	Malformations detected antenatally/IUGR
Neonatal history	Birthweight, length, head circumference	Primordial dwarfism—Seckel syndrome, Silver-Russel syndrome, de Lange syndrome
	Feeding difficulties Floppy baby	Prader-Willi syndrome
Details of developmental history		MR as a part of the syndrome
Behavioral patterns		Angelman syndrome, Prader-Willi syndrome, Williams syndrome

Abbreviations: CMV, cytomegalovirus; HSV, Herpes simplex virus; IUGR, intrauterine growth restriction; MR, mental retardation.

interferes with function; e.g., cleft lip and palate, heart defects. Some major malformations suggest a specific disorder:

- Left sided heart defects namely, coarctation of aorta, bicuspid aortic stenosis in Turner syndrome
- Atrioventricular canal defects in Down syndrome
- Duodenal atresia in Down syndrome

**Minor malformations** are mostly of cosmetic significance, e.g., prominent ear crus, ear tag, polydactyly. However, they serve as tools for diagnosis of a malformation syndrome. In the presence of 1 minor anomaly only 3% of the babies have an associated major malformation compared with babies with 2 and 3 or more minor anomalies where 11% and 90% babies, respectively, have associated major malformations.

- Malformations have to be differentiated from:
  - (i) **Deformations** like clubfoot due to antenatal oligohydramnios which occur due to abnormal mechanical forces causing abnormality of shape and form. This will not recur in the absence of the initiating factor.

- (ii) A **disruption** is a sporadic defect that occurs due to an abnormal extrinsic factor that interferes with otherwise normal morphogenesis. An amniotic band syndrome is a disruption presenting with asymmetric limb amputations with associated bizarre malformations of central nervous system (CNS) and cleft lip or palate. This is a sporadic event with a negligible recurrence risk.

- (iii) A **dysplasia** is the morphological consequence of an abnormal organization of a specific tissue type during morphogenesis. Examples include ectodermal dysplasia comprising abnormal development of structures derived from the ectoderm, e.g., teeth, inability to sweat due to abnormality of sweat glands, and poor hair growth.

When multiple anomalies come together the resulting phenotype is either a multiple malformation syndrome, an association or a sequence. A multiple malformation syndrome has been defined before in this chapter. This has to be differentiated from an *association* which includes an unrelated group of abnormalities but whose occurrence occurs together more often than by chance alone. Examples include VACTERL (vertebral, anal, cardiac, tracheal, esophageal, renal, limb). Some cases previously described as associations are found to be caused by genetic defects. One example is *CDH7* gene mutations in CHARGE syndrome (C-coloboma of iris or retina, H-heart defects A-atresia of the choanae, R-retardation of growth and development, G-genital anomalies, mostly in the male and E-ear abnormalities) thought to be CHARGE association previously. A knowledge of these is important so that a pediatrician can search for the other associated anomalies after one is identified.

**Sequence** is a specific pattern of abnormality that results due to a cascade of events due to one malformation or disruption. In Potter sequence, renal agenesis is the primary malformation that causes oligohydramnios that in turn results in clubfeet, flat facies and hypoplastic lungs.

Important points in examination for syndrome diagnosis are noted in **Table 2**. *Pearls of dysmorphology* refer to features that signify a specific diagnosis. Some common *pearls of dysmorphology* are noted in **Table 3**. Documentation with a detailed description of the phenotype, measurements and photographs is the key step in dysmorphology diagnosis. Photographs are important in dysmorphology and speak for multiple words and lengthy descriptions. Consent for this should be taken from the parents or proband as applicable.

## Investigations

Investigations in a child with a developmental defect depend on the nature of the defect. Some investigations are important to identify diagnostic handles in the process of diagnosis making whereas other are diagnostic tests to confirm a clinical suspicion.

- **Imaging** Radiographs for bone age and skeletal abnormalities where there are abnormalities of growth and skeletal defects. Brain CT scan or MRI is very useful in syndromes with known abnormalities of CNS, e.g., acrocallosal syndrome, Walker-Warburg syndrome, other cases like craniosynostosis, microcephaly and macrocephaly.
- **Echocardiography** It should be done in all cases with an abnormal cardiac examination as well as in some syndromes known to be associated with cardiac defects, e.g., Down syndrome, Williams syndrome, Turner syndrome.
- **Chromosomal analysis** This is an important investigation in dysmorphology and common indications include:
  - Presence of a typical defined chromosomal syndrome like Down syndrome, trisomy 18.
  - Malformations associated with a high incidence of chromosomal defect, e.g., omphalocele, holoprosencephaly.

**Table 2** Examination points in dysmorphology

Feature	Abnormality	Syndromes
i Growth parameters	Growth restriction	Proportionate Primordial short stature Seckel syndrome, de Lange syndrome
		Postnatal GR Noonan syndrome
	Disproportionate	Skeletal dysplasia Diastrophic dysplasia Chondrodysplasia punctata
	Overgrowth	Overgrowth syndromes Sotos syndrome, Beckwith-Wiedemann syndrome, etc
ii Asymmetry		Goldenhar syndrome Silver-Russell syndrome
iii Genitalia	Abnormal genitalia/delayed puberty	Smith-Lemli-Opitz syndrome
iv Intellectual disability	Common feature of many syndromes	Down syndrome, Fragile-X mental retardation
v Eye examination	Chorioretinal lacunae Salt and pepper retinitis	Aicardi syndrome TORCH infections
Consider variable features present in the child and parent as <i>normal variants</i>		

Abbreviations: GR, growth retardation; TORCH, toxoplasmosis other (syphilis) rubella cytomegalovirus (CMV) herpes simplex (HSV).

**Table 3** Pearls of dysmorphology

Clinical feature	Syndrome
Pursed up lips ( <b>Fig. 1</b> )	Whistling face syndrome
Broad thumb/great toe ( <b>Figs 2A and B</b> )	Rubinstein-Taybi syndrome
Hyperextensible joints/skin	Ehlers-Danlos syndrome
Absent clavicles	Cleidocranial dysplasia
Heterochromia iridis ( <b>Fig. 3</b> )	Waardenburg syndrome
Bird-headed dwarfism ( <b>Fig. 4</b> )	Seckel syndrome
Inverted nipples and abnormal fat distribution ( <b>Figs 5A and B</b> )	Congenital disorder of glycosylation
Webbed neck	Turner syndrome, Noonan syndrome
Mitten hands	Apert syndrome

**Figures 2A and B** Broad toes and deviated broad thumbs: Rubinstein-Taybi syndrome**Figure 1** Pursed lips: Whistling face syndrome**Figure 3** Heterochromia iridis: Waardenburg syndrome

- A child with intellectual disability, physical retardation, ambiguous genitalia, malformations and dysmorphic features.
- A child with nonspecific dysmorphism not suggestive of a definite syndrome.
- **Fluorescence in situ hybridization (FISH)** A technique where the probe binds to a definite region of the chromosome, is indicated in cases of microdeletion syndromes. Unlike

- chromosomal analysis, for this test a definite microdeletion syndrome has to be suspected and tested for. Common microdeletion syndromes include Williams syndrome, 22q11 microdeletion, Prader-Willi syndrome, Miller-Dieker syndrome, Angelman syndrome.
- **Subtelomeric deletions** This group of disorders due to deletions in the sub telomeric regions is identified by defined FISH

**Figure 4** Prominent nose, high nasal bridge, micrognathia: Seckel syndrome

probes or multiplex ligation-dependent probe amplification (MLPA) technology. In a study by Kausik et al., an overall detection rate of 4.6% in children with intellectual disability, compares with 13% in children with associated dimorphism.

- **Cytogenomic microarray (CMA)** is a platform used for detection of chromosomal gains and losses of very small sizes which are undetectable by traditional karyotyping. CMA is very useful in the setting of intellectual disability, autism and/or congenital anomalies. CMA identifies chromosomal aberrations in additional 10–20% cases and is now recommended as a first-tier investigation. However in India, cost and interpretation expertise are current limiting factors and need to be considered before ordering the test.
- **Molecular diagnosis** The causative genes are now identified for many disorders, e.g., Coffin-Siris syndrome, Joubert syndrome, Crouzon syndrome and should be tested if indicated in a specific case. Most common indications for confirmatory molecular testing include an ambiguous diagnosis which needs confirmation, in preparation for prenatal diagnosis for the family and where predictive testing for unaffected family members or carrier testing for persons at risk is indicated.
- **Metabolic studies** Many metabolic disorders present with dysmorphism, e.g., Smith-Lemli-Opitz-syndrome, storage

disorders, galactosemia with cataract, peroxisomal disorders. The metabolic test ordered is case specific and based on the diagnosis entertained.

### Making a Dysmorphology Diagnosis

This involves synthesizing all the information of the history and clinical examination. Steps in making a diagnosis are as follows:

- Determine the underlying pathogenic mechanism, i.e., deformation, disruption, dysplasia or malformation.
- Where there are multiple malformations, syndrome identification proceeds as below:
  - Identification of the syndrome can be by fast recall of a facial gestalt and pattern recognition (**Case 2**). This is simple for common syndromes like Down syndrome, trisomy 13 (**Figs 6A to C**), Cornelia de Lange syndrome (**Fig. 7**), to name a few. However, as apparent, this is based on the experience and expertise of the examining physician and prone to errors. In our experience, even if a diagnosis is gestalt based, it is important to consider unusual features and refer to written text about that syndrome.

In other cases diagnosis occurs in stages. Few pivotal signs or *diagnostic handles* that are objective and not overly common are selected from the history, examination and investigations and these are correlated using search engines and databases (**Case 3**). Common online free search engines are Online Mendelian Inheritance in Man and PubMed. The computerized databases are LDDB and Pictures of Standard Syndromes and Undiagnosed Malformations. Based on the prioritization of the handles used a list of possible syndromes are suggested. These further have to be correlated with the phenotype of the proband. Books of malformation syndromes with pictures and phenotype help further to reach a probable diagnosis that then can be confirmed by a diagnostic test as indicated. Commonly used book is “*Smith’s Recognizable Patterns of Human Malformation*”. There are many excellent reviews with system wise detailed approach and diagnosis which can be referred to. It is also very useful to look at published case reports and compare the features of the case with the photographs and features of similar cases published. However, these databases and books are *systems for experts* and not experts to reach a diagnosis. Telemedicine and sharing pictures with expert

**Figures 5A and B** (A) Inverted nipples, and (B) Abnormal distribution of fat: Congenital disorder of glycosylation

**Figures 6A to C** Broad nose, microcephaly, cutis aplasia, polydactyly: Trisomy 13

**Figure 7** Cornelia de Lange syndrome

dysmorphologists can likely to aid in reaching a diagnosis.

- All listed features of a syndrome may not be present in each case and it is important to keep in mind the variability of phenotypes in different cases. This is especially true for autosomal dominant syndromes like Holt-Oram syndrome.
- A definite diagnosis of a syndrome where additional significant features are identified should be reported.
- Getting cases with features overlapping with two different syndromes is not unusual and suggests the possibilities of common etiologies like allelic disorders or genes involved in a common developmental pathway.

In evaluating a child with anomalies, it is important not to miss a treatable disorder like hypothyroidism, craniosynostosis, scoliosis, Smith-Lemli-Opitz syndrome. Equally important is surveillance for treatable associated malformations like atlantoaxial dislocation in syndromes with joint laxity. It is important not to rush to a diagnosis, as it is difficult to remove or correct an incorrect diagnostic label of a patient. Many times, despite all efforts a diagnosis is not defined. This must be noted as such and the child kept under follow up. Evolution of the syndrome with time, similar phenotypes that are published in literature and rapid advancement with new technology can help the family at a later follow-up.

### Case 2: Gestalt Diagnosis

A 28 years old second gravida was referred at 32 weeks for an antenatally detected fetal double bubble appearance. A possibility of trisomy 21 was kept and the family was offered amniocentesis. However, they declined amniocentesis. At birth, the neonate had duodenal atresia and looked different from his sibling and parents. He was hypotonic, had brachycephaly, bilateral upslant of eyes with epicanthic folds. The bridge of nose was depressed and ears were low set. The hands were small and there was fifth finger clinodactyly. There was increased distance between the first and second toe, referred to as a sandal gap. The pediatrician suspected Down syndrome that was confirmed on chromosomal analysis.

Based on gestalt, the diagnosis of Down syndrome was confirmed. Chromosomal analysis confirmed trisomy 21 and the family was counseled for management.

Gestalt diagnosis for Down syndrome is easy to make as this is not an uncommon syndrome and most pediatricians and all geneticists have seen these children. However, it is important to know and consider differential diagnosis of syndromes with a similar phenotype—Zellweger syndrome, 9q deletion, Smith-Magenis syndrome.

### Case 3: Evaluation Using Diagnostic Handles

A 2-month-old male child had an abnormal shape of the head with limb abnormalities. Examination showed a cloverleaf shaped skull, bilateral duplication of the great toe with postaxial polydactyly of one upper limb. There was hypertelorism with narrow palpebral fissures, midfacial hypoplasia and prominent anthelix. A previous similarly affected sibling was noted to have an abnormal shaped skull with ambiguous genitalia. The parents were normal and there was no other significant family history.

Good diagnostic handles in this case for a London Medical Database search are cloverleaf skull and hallux duplication. These are rare malformations present in few syndromes compared to hypertelorism, ambiguous genitalia and mid facial hypoplasia, which are nonspecific and present in many syndromes. Search with autosomal recessive craniosynostosis syndromes show 102 results, but when combined with polydactyly or hallux duplication, it narrowed it to two disorders, Carpenter syndrome and Baller-Gerold syndrome. Comparing the phenotypes and photographs of published cases, a final diagnosis of autosomal recessive Carpenter syndrome was made and confirmed by identification of mutations in *Rab23* gene.

### IN A NUTSHELL

1. Detailed head to toe clinical examination complements a good history.
2. Be careful of the sentiments of the family while evaluating the proband for dysmorphic features.
3. Take good photographs to document dysmorphism after informed consent.
4. Dysmorphology databases are not experts but tools for experts.
5. Confirmation of diagnosis is important for anticipatory management and counseling for recurrence risks.

## Chapter 2.4

# Chromosomal Disorders

Shagun Aggarwal, Ashwin Dalal

Chromosomes or colored bodies (as the word means) have been recognized for more than 100 years when Walther Flemming first demonstrated them in mitotic tumor cells in 1882. They were given their name by Waldeyer in 1882 and the chromosomal theory of inheritance was proposed in 1900 by Sutton and Boveri. In the year 1923, Painter reported the human diploid chromosome number as 48 on the basis of his studies on meiotic cells in testicles. For a long 30 years this was believed to be the case, till better cytogenetic techniques and the advent of hypotonic treatment helped scientists study the chromosomes better. In 1956, the correct human diploid chromosome number, i.e., 46 was reported by Tijo and Levan. This was followed by the description of chromosomal basis of Down syndrome in 1959. Lejeune and his team reported 47 chromosomes in patients with Down syndrome and showed that the smallest chromosome, which we now know as chromosome 21 was 3 in number in these patients. Subsequently, in quick succession the Patau syndrome and Edward syndrome were described. The necessity of performing bone marrow aspiration for obtaining dividing cells was obviated in 1960s when Moorhead et al described a method of obtaining good quality metaphases from small amount of peripheral blood samples using combination of phytohemagglutinin for stimulation of lymphocyte culture and air-drying technique for metaphase preparation. However, the recognition of other chromosomal abnormalities was possible only after the chromosomal banding techniques were developed. In 1968, Caspersson and colleagues used quinacrine hydrochloride to differentially stain various regions of the chromosomes. This was followed by the development of the Giemsa banding technique by Drets and Shaw a year later, and this led to the identification of each of the human chromosome by their different banding patterns. The chromosomes could now be identified and arranged systematically, and the human karyotype (defined as the orderly arrangement of chromosomes) could be prepared. Subsequently, a number of chromosomal abnormalities were described like the various deletions, translocations and inversions. The era of cytogenetics had arrived and progressed further with the advent of fluorescence in situ hybridization (FISH) technology in the 1990s. This was followed by development of other molecular cytogenetic techniques like quantitative fluorescent-polymerase chain reaction (QF-PCR), multiplex ligation dependent probe amplification (MLPA) and chromosomal microarray which helped scientists study the chromosomes in much finer details and lead to the recognition of many new genetic disorders.

### NOMENCLATURE OF CHROMOSOMES

The diploid human chromosomes are 46 in number. Each chromosome in metaphase consists of two *chromatids* attached at the center by a structure called *centromere*. There are two arms of the chromosome on either side of the centromere, the p arm and the q arm. The ends of the chromosomes are known as *telomeres*. Individual chromosomes can be identified and numbered according to size, length of arms, position of centromeres and banding patterns.

There are 22 pairs of autosomes numbered 1 to 22 and one pair of sex chromosomes which are XX in females and XY in males. **Figures 1A to D** shows a diagram of the chromosome, the appearance of chromosomes under microscope and their

arrangements into a male karyotype and a female karyotype. The autosomes are arranged in the descending order of their size. Three main types of chromosomes can be distinguished depending on the position of the centromere. Chromosomes whose centromere is at the center are known as the *metacentric chromosomes*, e.g., chromosomes 1, 2, 3, 16, 19 and 20, those with centromere more towards one of the arms are called *submetacentric chromosomes*, e.g., chromosomes 4, 5, 6, 7, 8, 9, 10, 11, 12, 17, 18, X and the ones with centromere near the end of the q arm, the p arms being replaced by satellites are termed *acrocentric chromosomes*, e.g., chromosomes 13, 14, 15, 21, 22 and Y. These have also been grouped as Group A: the large metacentric chromosomes no. 1, 2, 3; Group B: the large submetacentric chromosomes no. 4, 5; Group C: chromosomes 6–12 and X; Group D: the large acrocentric chromosomes no. 13, 14 and 15; Group E: 16, 17, 18; Group F: 19, 20; and Group G: 21, 22 and Y.

Chromosomal banding refers to the differential staining of the different parts of a chromosome and this can be achieved by pretreatment with various chemicals before staining. On Giemsa banding after trypsin digestion, some regions of the chromosome stain lightly, these are mainly the guanine and cytosine (GC) rich regions; while others stain darkly, these being adenine and thymine (AT) rich. The banding characteristics of individual chromosomes help in identification of the chromosomes and the diagnosis of the various structural chromosomal abnormalities.

Chromosomal abnormalities may be inherited from the parents or may occur due to errors in meiotic segregation of chromosomes. Chromosomal abnormalities can be classified as numerical and structural chromosomal abnormalities.

### NUMERICAL CHROMOSOMAL ABNORMALITIES

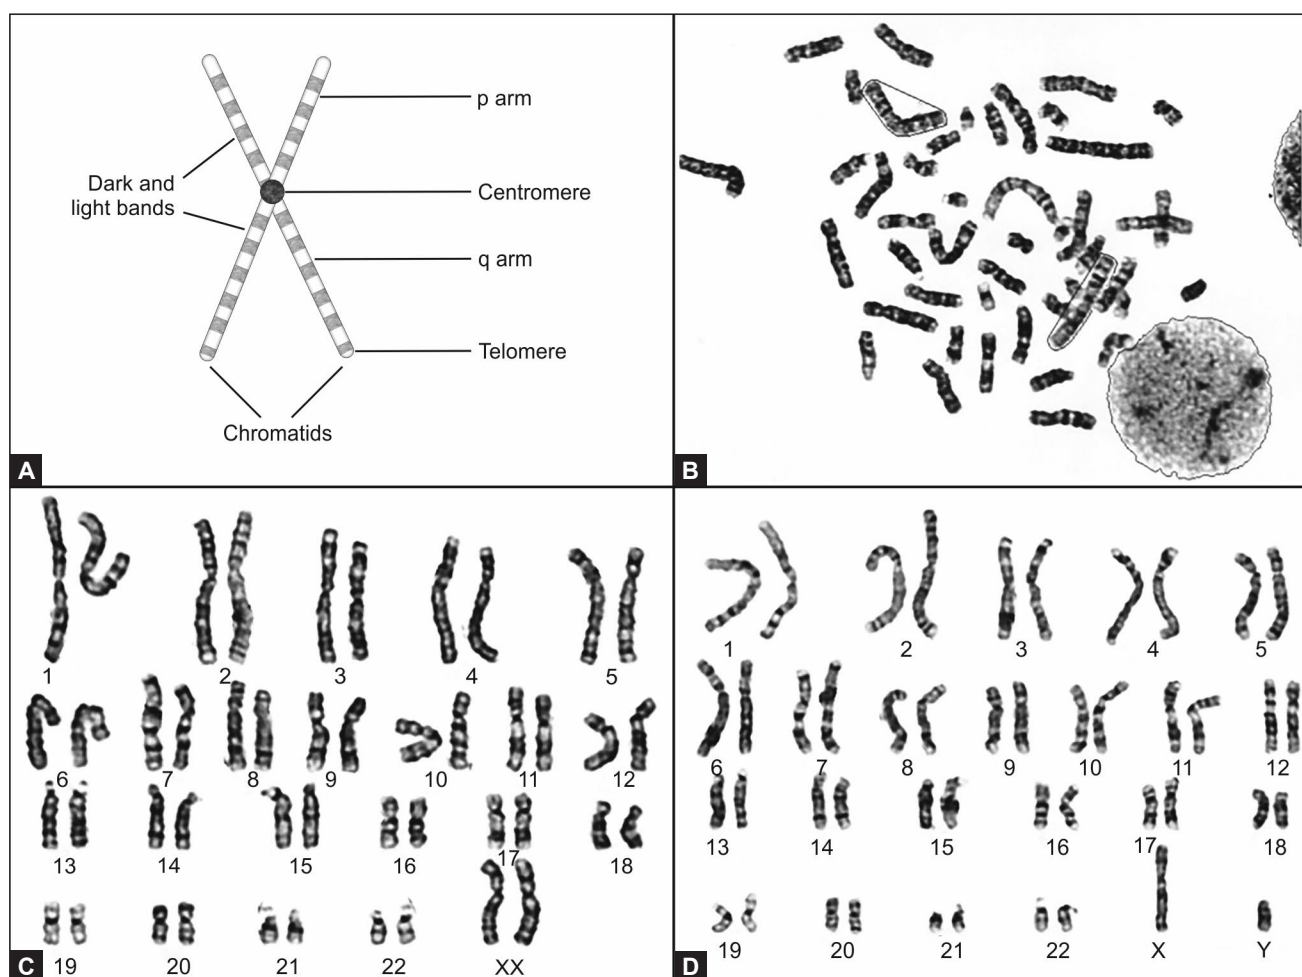

The normal human chromosome complement is made up of 46 chromosomes (diploid) which is double the euploid (haploid) complement of 23 chromosomes seen in gametes. Exact multiples of euploid chromosome complements can be diploid or polyploid, i.e., triploid or tetraploid consisting of three or four sets of chromosomes, respectively. Aneuploidy refers to the presence of extra copy of a specific chromosome (trisomy), as seen in Down syndrome (trisomy 21) or to the absence of a single chromosome (monosomy), as seen in Turner syndrome (monosomy X). Polyploidy and aneuploidy result from errors in segregation of chromosomes during cell division (meiosis) leading to either loss or gain of chromosome in the gametes. Similar errors in mitotic cell division of zygote (fertilized egg) can lead to simultaneous presence of both diploid and aneuploidy cell populations in an individual. This is termed as *mosaicism*. The clinical relevance of mosaicism depends on the proportion and tissue distribution of the aneuploid cells. On the other hand, presence of different cell lines derived from more than one zygote in an individual is called *chimerism*.

Polyploidy resulting from triploidy (69 chromosomes) or tetraploidy (92 chromosomes) is mostly lethal and seen frequently in spontaneous abortions. Most of the aneuploidies are also incompatible with life in humans, with exception of trisomy 13, 18, 21 and X chromosomal aneuploidies. Absence of a chromosome is more detrimental than presence of an extra chromosome.

### Down Syndrome: Trisomy 21

Down syndrome (trisomy 21) is a chromosomal abnormality that occurs in approximately one in every 800–1,000 livebirths. It was first described in 1866 by John Langdon Down, the superintendent of a facility for children with mental retardation in England. Jean Lejeune and his colleagues identified the genetic cause of Down syndrome in 1959.

**Figures 1A to D** (A) Diagram showing structure of a chromosome; (B) Chromosomes in metaphase as seen under 100X magnification; (C) A normal female karyotype; (D) A normal male karyotype

### Mechanism

Trisomy 21 can occur in one of the three forms:

**Meiotic nondisjunction** Meiotic nondisjunction is an error occurring during separation of the pair of chromosomes during meiotic cell division in the process of formation of gametes (sperm or egg). If it occurs for chromosome 21 then, the gamete will get 2 copies of chromosome 21 leading to trisomy 21 in the zygote. A patient with Down syndrome has 47 chromosomes in every cell (as compared with the normal 46). This is the most common cause of Down syndrome and it accounts for about 95% of cases. **Figure 2A** shows karyotype of a child with Down syndrome due to nondisjunction.

**Translocation Down syndrome** About 3% of patients with Down syndrome have the extra copy of chromosome 21 attached (translocated) to another chromosome. The other chromosome may be one of the acrocentric chromosomes, i.e., chromosome 13, 14, 15, 21 or 22. All cells have 46 chromosomes plus extra chromosome 21 material attached to another chromosome. About 50% of translocations occur spontaneously. The other half happens as a result of inheritance of translocated chromosome from a parent with a balanced translocation (the parent has 45 chromosomes, one free normal chromosome 21 and the other chromosome 21 attached to some other chromosome). **Figure 2B** shows a parent who is carrier of t(14; 21), and can give birth to a child with translocation Down syndrome.

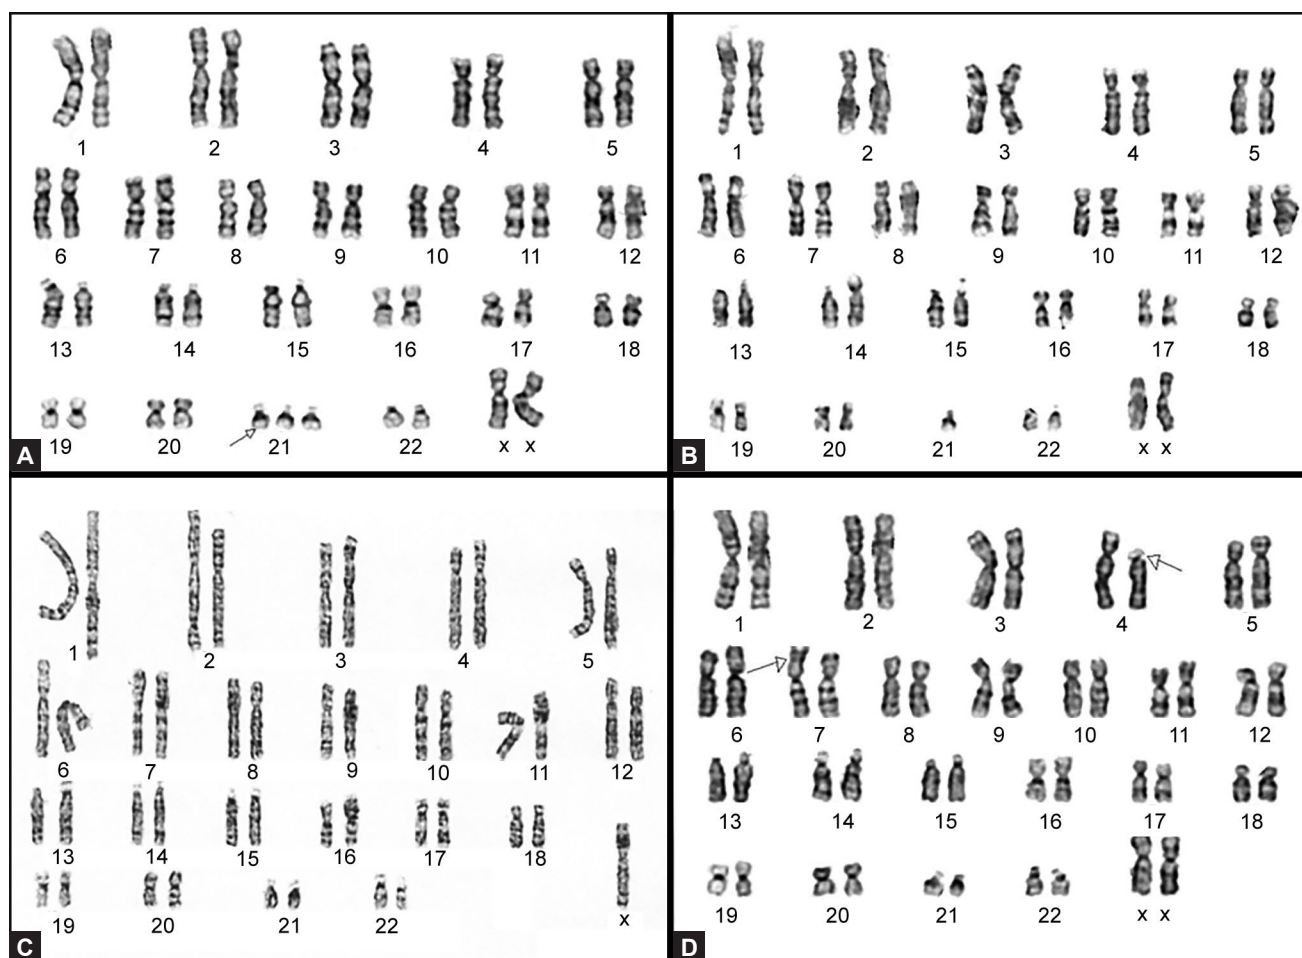

**Mosaicism** Approximately 2% of children with Down syndrome have mosaicism wherein the patient has both normal diploid cells as well as cells with trisomy 21.

### Clinical Features

Down syndrome is characterized by mental subnormality (intellectual disability), typical facial dysmorphism and malformations of different organs. All the characteristic facial features are not obvious in neonatal period and diagnosis may be difficult. Clinical signs in a neonate which point towards Down syndrome include small ears, wide space in between the first and second toe (*sandal gap*), small internipple distance, Brushfield spots, increased nuchal skinfold, brachycephaly, hypotonia, flat face, upward slant of palpebral fissures and transverse line in the palm of the hand (*simian crease*). As the child grows older, the facial features become more and more discernible. Apart from facial features, the child with Down syndrome is at risk of multiple clinical problems as detailed in **Table 1**.

### Diagnosis

Diagnosis of Down syndrome is obvious in most cases from the facial features (**Fig. 3A**). However, this needs to be confirmed in every patient by doing chromosomal analysis. Karyotype also helps to detect Down syndrome due to translocation and mosaicism which helps in providing accurate risk of recurrence (**Box 1**).

**Figures 2A to D** (A) Karyotype of a child with Down syndrome showing free trisomy 21; (B) Karyotype of a female  $t(14; 21)$  carrier; (C) Karyotype of a patient with Turner syndrome; (D) Karyotype of a female with  $t(4; 7)$

### Management

Down syndrome management is done through a multidisciplinary approach. The details of clinical problems associated with Down syndrome and their management are shown in **Table 1**.

### Prenatal Screening and Prenatal Diagnosis

The risk of having a baby with Down syndrome increases with maternal age. A lady at an age of 45 carries a risk of up to 1 in 15 of having a child with Down syndrome. This phenomenon has been used as a screening method for selecting patients for prenatal diagnosis. However, various screening protocols have evolved over last decade consisting of maternal serum markers and ultrasonographic markers with marked increase in the sensitivity and specificity. A brief list is presented in **Table 2**. All the screening protocols give a risk figure which is then compared with the risk of abortion following an amniocentesis. A risk of 1:250 or more is taken as significant and the couple is advised prenatal diagnosis. Prenatal diagnosis can be done by karyotyping the fetal cells obtained by chorionic villus sampling or amniocentesis. The couple can opt for termination of pregnancy in case the fetus is having Down syndrome or any other chromosomal abnormality.

### Genetic Counseling

Genetic counseling includes providing the family with confirmed diagnosis and information regarding prognosis in a child with

Down syndrome. It should be done as soon as the diagnosis is suspected or confirmed after birth. It is very important to convey to the parents regarding the clinical problems in Down syndrome as well as information about absence of any definitive treatment. Treatment of clinical problems detected and screening protocol for future needs to be discussed. Further the couple is explained about the risk of Down syndrome in subsequent pregnancy and the option of prenatal diagnosis (**Box 1**).

### Other Autosomal and Sex Chromosome Trisomies

Autosomal trisomies compatible with life in humans, other than Down syndrome are Edward syndrome (trisomy 18) and Patau syndrome (trisomy 13) as shown in **Figure 3B** and **Table 3**. Most of these children do not survive beyond 2 years of age.

Sex chromosome aneuploidies are less detrimental as compared to autosomal aneuploidies. This could be due to phenomenon of X chromosome inactivation and paucity of significant genes on Y chromosome. Clinical features of sex chromosome aneuploidies and their incidence is shown in **Table 3**.

### Turner Syndrome: Monosomy of X Chromosome

Turner syndrome is a chromosomal disorder caused due to partial or complete loss of one X chromosome. The disease incidence is approximately 1 in 2500 live born females. A 45, X karyotype is observed in 1–2% of conceptuses, 10% of miscarriages and 1% of stillbirths. More than 99% of 45, X conceptuses are spontaneously aborted.

**Table 1** Clinical problems and management in children with Down syndrome

<i>Clinical problem</i>	<i>Description</i>
Congenital heart defects (CHD)	<ul style="list-style-type: none"> <li>• Atrioventricular septal defect and ventricular septal defect are the most common forms of CHD (54% ASD and 33% VSD)</li> <li>• Surgical correction of significant defects usually at the age of 2–4 months, sometimes earlier (tetralogy of Fallot)</li> <li>• Echocardiography in the first month of life helps in early recognition of CHD for optimal management and prevention of pulmonary hypertension</li> </ul>
Vision disorders	<ul style="list-style-type: none"> <li>• Ocular features include epicanthal folds, narrowed or slanted palpebral fissures (the mongoloid slant) and Brushfield spots (38–85%)</li> <li>• Vision disorders include strabismus (20–47%), nystagmus (11–29%), congenital cataract (4–7%), acquired cataract (3–15%), blepharitis (7–41%), refractive errors (43–70%) and glaucoma (0.7%)</li> <li>• Ophthalmological examination is essential for detecting defects that can be treated</li> </ul>
Hearing disorders	<ul style="list-style-type: none"> <li>• High incidence of chronic middle ear disease and chronic rhinorrhea</li> <li>• Regular assessment of the hearing function is very important</li> </ul>
Obstructive sleep apnea syndrome	<ul style="list-style-type: none"> <li>• High incidence due to macroglossia, glossoptosis, recurrent enlargement of the adenoid tonsils and enlarged lingual tonsils</li> <li>• Baseline polysomnography recommended in all children with Down syndrome at 3–4 years of age</li> </ul>
Wheezing airway disorder	<ul style="list-style-type: none"> <li>• Major cause of morbidity and hospital admissions</li> <li>• Respiratory syncytial virus infections common</li> <li>• Exacerbation due to associated airway anomalies like tracheolaryngomalacia, pulmonary hypoplasia, and subpleural cysts</li> </ul>
Congenital defects of gastrointestinal tract	<ul style="list-style-type: none"> <li>• Duodenal stenosis/atresia (1–5%), esophageal atresia/trachea-esophageal fistula (0.3–0.8%), pyloric stenosis (0.3%), Hirschsprung disease (1–3%) and anal stenosis/atresia (&lt; 1–4%)</li> </ul>
Celiac disease	<ul style="list-style-type: none"> <li>• Screening for early detection of celiac disease helps in starting treatment and preventing complications such as failure to thrive, anemia, osteoporosis and malignancy</li> <li>• Screening by human leukocyte antibodies (HLA)-DQ2 and HLA-DQ8 typing in the first year of life</li> </ul>
Transient myeloproliferative disorder	<ul style="list-style-type: none"> <li>• Thrombocytopenia (up to 66%) and polycythemia (up to 33%)</li> <li>• Lowered T- and B-lymphocyte counts and functions</li> <li>• Increased risk for acute myeloid as well as lymphoblastic leukemia</li> </ul>
Thyroid disorders	<ul style="list-style-type: none"> <li>• Congenital hypothyroidism (1.8–3.6%), primary hypothyroidism, autoimmune (Hashimoto) thyroiditis (0.3–1.4%), compensated hypothyroidism (25–33%), hyperthyroidism (Graves' disease) (0–2%)</li> <li>• Screening once a year recommended</li> </ul>
Orthopedic problems	<ul style="list-style-type: none"> <li>• Atlantoaxial instability (15%), extra care in intubation</li> <li>• Acquired hip dislocation (30%), patellofemoral instability (10–20%), slipped capital femoral epiphysis</li> <li>• Physiotherapy helps the development of the basic gross motor skills</li> </ul>
Skin problems	<ul style="list-style-type: none"> <li>• Alopecia areata (3–20%), vitiligo (1–9%), seborrheic eczema (8–36%), folliculitis (10–26%) and syringoma (12–39%)</li> </ul>
Behavior problems	<ul style="list-style-type: none"> <li>• Mental development shows a deceleration between the ages of 6 months and 2 years, IQ values vary from 35 to 70</li> <li>• Delayed verbal short-term memory and expressive language</li> <li>• Attention deficit hyperactivity disorder (6%), conduct/oppositional disorder (5%) or aggressive behavior (6%), and obsessive-compulsive disorders</li> <li>• Autism (7%), epilepsy (8%)</li> <li>• Alzheimer disease after childhood</li> </ul>

**BOX 1 Case Study: Down Syndrome**

Baby Aayushi is taken to her pediatrician for the 6th week vaccination. She is the first child of a Punjabi mother and Bengali father. Her parents are concerned about her loose limbs and recurrent cold episodes. The pediatrician notices the presence of dysmorphic features like upslanting palpebral fissures, brachycephaly, epicanthic folds and simian crease in right hand. He advises peripheral blood karyotype for the child.

Aayushi's karyotype report is shown in **Figure 2A**. Can you identify the condition?

The pediatrician told the couple that Aayushi has a genetic disease called Down syndrome or Trisomy 21 and referred them to the geneticist.

Aayushi's parents were counseled by the geneticist regarding the prognosis for her developmental milestones and subsequent intellectual challenges. They were advised to consult a psychologist for guidance regarding management of these problems. Aayushi was advised to go for cardiac echocardiography and thyroid function assessment. She was advised for regular follow-up for development assessment, ophthalmic and ENT checkups. The couple was also told about the need for prenatal diagnosis in subsequent pregnancies.

For women with previous child with Down syndrome due to free trisomy 21 (like Aayushi), the average recurrence risk for subsequent pregnancies is 1%. These women are offered direct amniocentesis and do not undergo screening test. The recurrence risk for the translocation Down syndrome is much higher (1–5% if father is carrier and 5–15% if mother is carrier).

**Table 2** Prenatal screening for Down syndrome

Screening strategy	Criteria/Parameter	Sensitivity
Maternal age only	> 35 years	30%
Triple marker assay from maternal serum (15–22 weeks)	Free beta-hCG, alpha-fetoprotein Unconjugated estriol	60–75%
Quadruple marker from maternal serum (15–22 weeks)	Inhibin Free beta-hCG Alpha-fetoprotein Unconjugated estriol	80%
Double marker from maternal serum (11–14 weeks)	PAPP-A Free beta-hCG	65%
Fetal ultrasonography (11–14 weeks)	Nuchal translucency	65–75%
Combined test (double marker and USG)	PAPP-A, Free beta-hCG, Nuchal translucency	85–90%
Combined test and nasal bone	Nasal bone assessment, PAPP-A, free beta-hCG and nuchal translucency	95%

Abbreviations: hCG, human chorionic gonadotropin; PAPP-A, pregnancy associated plasma protein A.

### Mechanism

The most common type of Turner syndrome results from errors in meiotic segregation of chromosomes, leading to one gamete with two X chromosomes and another with no X chromosome. This type of abnormality is seen in about 45% of patients and karyotype is 45, X. The other mechanisms of Turner syndrome include isochromosome Xq (15–18%), mosaic 45, X/46, XX (7–16%), ring X chromosome or partial deletion of Xp or Xq.

### Clinical Features

The clinical features of Turner syndrome include short stature, ovarian failure, edema of hands or feet, nuchal folds, left-sided cardiac anomalies, low hairline, low set ears, small mandible, cubitus valgus, nail hypoplasia, hyperconvex nails, multiple pigmented nevi, characteristic facies, short fourth metacarpal, and high arched palate (**Fig. 3C**). Isolated deletion of the distal region of Xp including the *SHOX* (short stature homeobox) gene may result only in short stature in females and these patients may not get diagnosed with Turner syndrome. Similarly, individuals with deletions of Xq24 are typically diagnosed with premature ovarian failure since they do not have short stature. The girls with Turner syndrome usually do not have intellectual disabilities but may have learning disabilities in some areas.

**Table 3** Clinical features of patients with common autosomal or sex chromosome aneuploidy

Syndrome/Karyotype	Incidence (per 1,000 livebirths)	Clinical features
Edward/Trisomy 18	1 in 3,000	Multiple congenital malformations of many organs, low-set malformed ears, receding mandible, small eyes, mouth and nose, clenched fist with overlapping fingers, severe mental deficiency, congenital heart defects, horseshoe or double kidney, short sternum, posterior heel prominence
Patau/Trisomy 13	1 in 10,000	Severe mental deficiency, small eyes, cleft lip and/or palate, extra fingers and toes, cardiac anomalies, midline brain anomalies, genitourinary abnormalities
Klinefelter/47,XXY	1 in 1,000	Male, infertile with small testes, may have some breast development, tall, learning disability, long limbs, at risk for educational problems
Trisomy X/47,XXX	1 in 1,000	Female with normal genitalia and fertility, at risk for educational and emotional problems, premature ovarian failure
47, XYY	1 in 1,000	Tall male with normal physical/sexual development, normal intelligence, increased tendency for behavioral and psychological problems

## Diagnosis

Chromosomal analysis is indicated in any female with short stature. Karyotype will reveal one of the different mechanisms of Turner syndrome described above (**Fig. 2C**). In addition, it is important to look for mosaicism for Y chromosome in these patients because of the risk of gonadoblastoma. Y chromosome mosaicism can be detected by cytogenetic analysis of chromosomes and detection of fluorescently labeled probes by FISH or by PCR-based methods.

## Management

A multidisciplinary team should oversee management of girls with Turner syndrome from diagnosis to adult life.

- Cardiovascular evaluation needs to be done at diagnosis, including physical examination and echocardiogram and/or MR angiography. Left-sided obstructive cardiac anomalies occur in 30% of girls with Turner syndrome. Bicuspid aortic valve (50%) and coarctation of aorta (30%) are commonly seen. Blood pressure should be measured annually, including arm and leg.
- Renal assessment needs to be done for urinary tract anomalies (30%) like renal rotational abnormalities and double collecting systems. Risks include hypertension, urinary infection and hydronephrosis.
- Free T4 and thyroid stimulating hormone at diagnosis and annually thereafter since primary hypothyroidism occurs in 10–30% of individuals with Turner syndrome.
- Hearing and visual assessment and management of problems detected.
- Patients are at risk of celiac disease and inflammatory bowel disease. Hence, antibody screening is indicated.
- Growth hormone (GH) therapy should be considered in all girls with Turner syndrome whose height is below the 5th centile for Turner syndrome and are not exhibiting significant catch-up on disease specific charts by 3–4 years age. Therapy with GH accelerates growth in patients with Turner syndrome and final height increments range from 5 cm to 15 cm. GH therapy also contributes to achievement of peak bone mass in combination with estrogen.
- Hormone replacement therapy under supervision of pediatric endocrinologist. Estrogen is essential for the physical changes of puberty including breast development, uterine and pelvic growth, and the psychological, social, emotional and sexual evolution of puberty. But, since estrogen also potentially accelerates fusion of bony epiphyses, the timing of its commencement must be coordinated to avoid undue delaying of onset of puberty.

## STRUCTURAL CHROMOSOMAL ABNORMALITIES

Abnormalities in the structure of one or more chromosome constitute an important group of chromosomal disorders. These abnormalities can be broadly categorized into two types:

1. **Unbalanced chromosomal abnormalities** These are associated with net loss or gain of chromosomal material and constitute the deletions, duplications and unbalanced chromosomal translocations (**Figs 4A and B**).
2. **Balanced chromosomal rearrangements** These do not lead to change in genomic content and consist of the inversions and the balanced translocations (**Figs 4C and D**).

### Unbalanced Chromosomal Abnormalities

The unbalanced chromosomal abnormalities present with phenotypic abnormalities of various types depending on the location and extent of the genomic imbalance.

**Deletions** involve loss of a part of a chromosome. These can occur as pure deletions or as part of a derivative or recombinant. The common pure deletions which can be detected on a karyotype are as follows:

- **4p-deletion/Wolf Hirschhorn syndrome** This is a subtelomeric deletion involving the terminal end of p arm of the chromosome 4. The cardinal clinical features are mental retardation, a *Greek helmet* appearance of nose, cleft lip or palate, preauricular tags and multisystem malformations.
- **5p-/Cri-du-Chat syndrome** This is a subtelomeric deletion involving the terminal end of the chromosome 5. The cardinal clinical features are a cat like cry, mental retardation, hypertelorism, microcephaly and downturned angles of mouth.
- **1p36 deletion syndrome** This is a subtelomeric deletion involving terminal part of p arm of chromosome 1. These children present with severe mental retardation, seizures, multiple malformations and facial dysmorphism in the form of straight eyebrows and deep set eyes.

Besides these large deletions which can be seen on a karyotype, many chromosomal deletions are too small to be seen under microscope. These are known as the microdeletions and are described in the subsequent section.

**Duplications** involve gain or duplication of part of a chromosome. Many duplications are tandem duplications where a segment of a chromosome is contiguously duplicated. Most tandem duplications are not easily seen on a karyotype and we need various molecular cytogenetics techniques to detect them. However, sometimes the extra or duplicated chromosome material can be present as a derivative chromosome, a recombinant, a dicentric, an isochromosome or a separate fragment in the cell called a marker chromosome. Some duplications detected on a karyotype are as follows:

**Tetrasomy 12p/Pallister-Killian syndrome** is a mosaic tetrasomy of p arm of chromosome 12, in which a metacentric isochromosome composed of two p arms of chromosome 12 is present in a proportion of body cells. The clinical features include polydactyly, mental retardation, hyperpigmented streaks on skin and coarse facial features. **Cat eye syndrome** due to tetrasomy of q arm of chromosome 22 presents with iris coloboma, anal atresia, preauricular tags and mental retardation. **Pseudodicentric 15** due to tetrasomy of part of chromosome 15 presents with mental retardation, autism and facial dysmorphism.

### Unbalanced Chromosomal Translocations

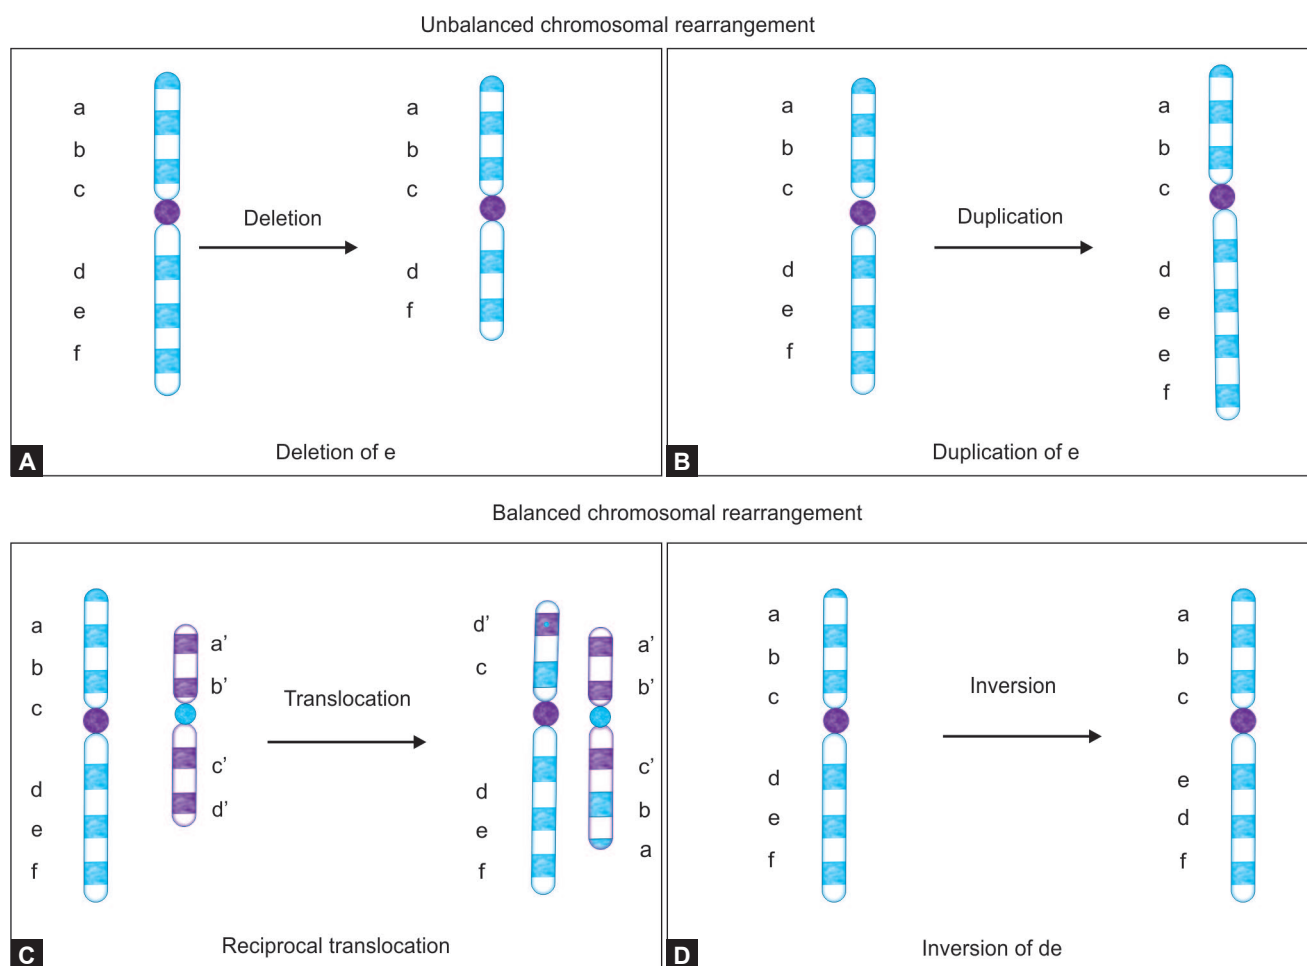

Translocations involve the exchange of genomic material between two or more chromosomes. This exchange can be balanced, where no material is lost or gained and this is discussed in the next subsection. Sometimes a translocation can involve gain or loss of chromosomal segments at the breakpoints. Usually, in karyotypes with unbalanced translocation, there is duplication (trisomy) of one segment and deletion (monosomy) of one segment of the involved chromosomes. Some of such unbalanced translocation may be inherited from a parent with balanced translocation. In these cases the patient develops a phenotype depending on the deleted and/or duplicated material.

## Balanced Chromosomal Abnormalities

### Inversions

These are intrachromosomal rearrangements where a segment of chromosome breaks and gets reinserted in the same place in a reverse orientation. One in 1,000 individuals is a carrier of an inversion. These are of two types: pericentric inversions, where the breakpoints of the inversion lie on either side of the centromere

**Figures 4A to D** (A) Diagram depicting a deletion; (B) Diagram depicting a duplication; (C) Diagram depicting a reciprocal translocation; (D) Diagram depicting an inversion

and the paracentric inversions, where both the breakpoints are in one of the arms. Many inversions are recurrent in the human population and 85–90% are inherited from one of the parent. Inversion carriers are asymptomatic individuals, however, some of the inversions can lead to reproductive problems due to abnormal meiotic recombination. The risk of an abnormal offspring in an inversion carrier is approximately 5–10%.

### Translocations

These arise due to exchange of material between two or more chromosomes. One in 500 individuals is a carrier of a balanced translocation. These are of two main types:

1. **Reciprocal translocation** The exchange of genomic material between two non-homologous metacentric or submetacentric chromosomes. **Figure 2D** shows karyotype of a translocation carrier.
2. **Robertsonian translocation** Translocations involving the extreme ends of two acrocentric chromosomes leading to loss of the satellites and fusion of their q arms.

### Clinical Presentation of Balanced Translocation Carriers

Individuals with balanced translocations are phenotypically normal. However, they can present with reproductive problems due to formation of abnormal synapses during meiosis 1. Five percent of couples with recurrent abortions and 1% of couples with

unexplained infertility have balanced chromosomal translocations. Usually the male partner presents with infertility as abnormal synapse formation leads to gametogenesis arrest in males. The female partner presents with recurrent pregnancy losses or recurrent abnormal offspring. The risk of abortion is approximately 25% for the female carrier of a translocation. The risk of abnormal offspring varies according to various factors like the mode of ascertainment, sex of carrier parent, type of rearrangement and predicted segregation patterns. On an average, if there is history of a liveborn abnormal offspring, the risk of recurrence is 5–30% and if the translocation was ascertained due to reproductive problems, the risk of an abnormal live offspring is 0–5%. Usually the risk is 5–15% if the carrier is the female partner and 0–5% if it is the male partner (**Box 2**).

Other rare structural chromosomal rearrangements are the insertions, ring chromosomes and centromere fissions.

### MICRODELETION AND MICRODUPLICATION SYNDROMES

The resolution of routine cytogenetic testing is about 5 Mb. This means that any deletion or duplication of less than 5 million base pairs will not be detected. However, the availability of high resolution methods like FISH and array comparative genomic hybridization (CGH) has enabled detection of smaller chromosomal rearrangements. Microdeletions or microduplications are

**BOX 2 Case Study: Translocation Carrier**

A couple was referred to the geneticist from their gynecologist in view of recurrent pregnancy losses in the first trimester with no identifiable cause. On pedigree analysis it was found that the wife's two brothers were infertile. A peripheral blood karyotype was done for the couple and the results are depicted in **Figure 2D**. The wife was found to be carrier of t (4; 7) and the couple was told that this was the possible cause of the recurrent pregnancy losses. The same translocation was found in the brothers of the wife.

The couple was also told about the need for prenatal diagnosis by amniocentesis in subsequent pregnancies as this translocation could lead to birth of a phenotypically abnormal child.

small (< 5 Mb) chromosomal rearrangements and the disorders resulting from alteration of gene dosages due to which these rearrangements are known as microdeletion or microduplication syndromes. They are frequently associated with mental subnormality and multiple congenital anomalies. The phenotype

is a cumulative result of haploinsufficiency or overexpression of a set of genes involved in the rearrangement. A list of common microdeletion or microduplication syndromes is shown in **Table 4**. Clinical photographs of some patients are shown in **Figures 5A to C**.

Microdeletions or microduplications can be detected by FISH using locus specific fluorescently labeled probes for a particular genomic region. However, newer techniques like MLPA can detect multiple microdeletions or microduplications in a single assay. The advent of array CGH has made it possible to scan the genome with resolution of few hundred base pairs and this has led to description of large number of novel microdeletion or microduplication syndromes in recent past.

**CYTOGENETIC TESTING****Chromosomal Analysis (Box 3)**

The karyotype of an individual can be investigated by studying the chromosomes in metaphase. These are obtained from any living body cells like peripheral blood lymphocytes, amniocytes, skin fibroblasts and chorionic villus cells by a series of steps in the cytogenetics laboratory. These involve cell culture, metaphase arrest using colcemide, treatment with hypotonic saline and fixative, spread of chromosomes on slide and staining followed by visualization under a microscope (**Fig. 6A**). Peripheral blood sample for karyotyping should be collected in a heparin vial under aseptic precautions. Blood samples need to reach the laboratory with 48 hours for chromosomal analysis.

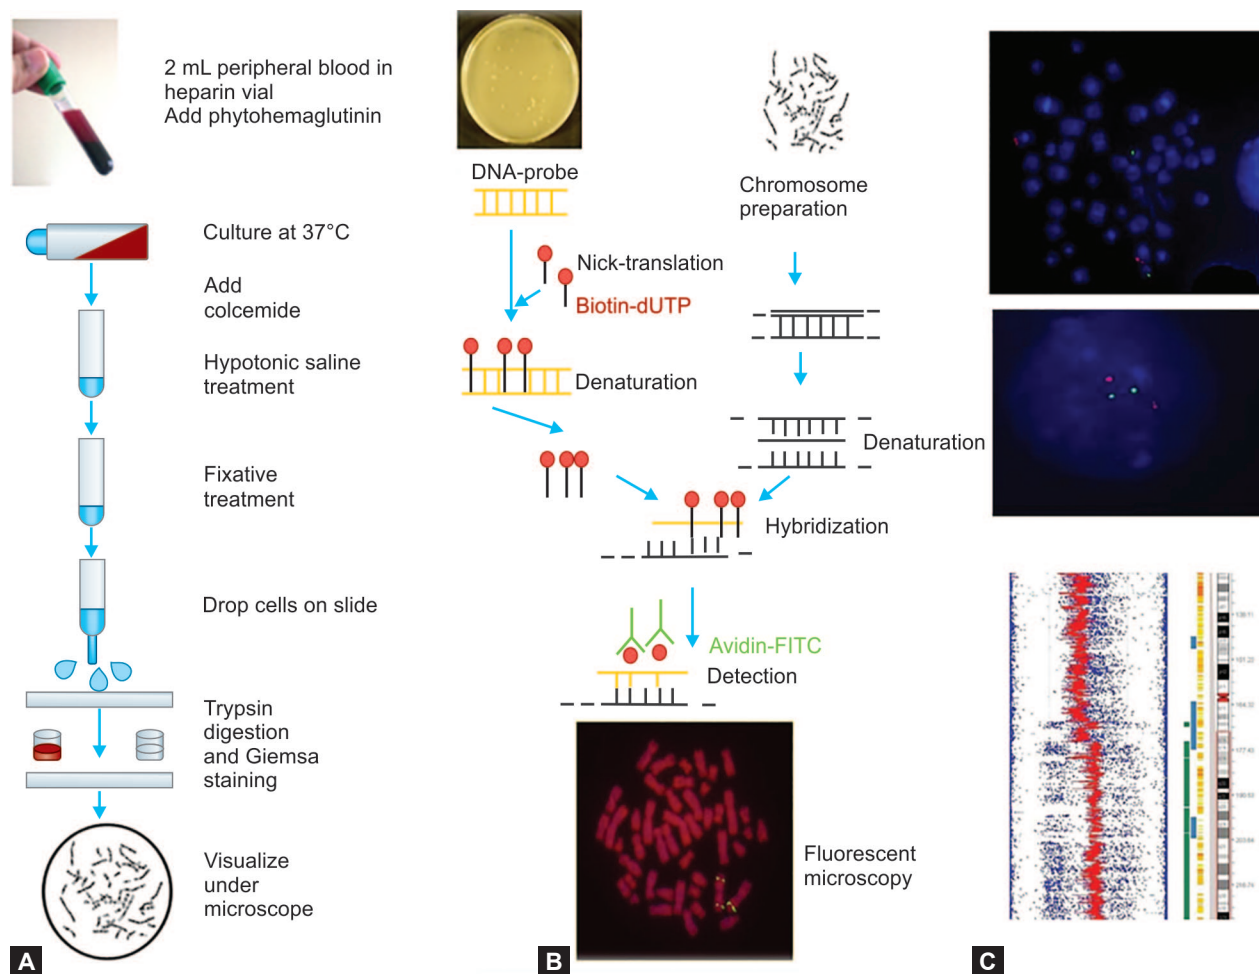

**Table 4** Common microdeletion/microduplication syndromes

Syndrome	Chromosome region	Clinical features
<b>Microdeletion syndromes</b>		
Prader-Willi syndrome	15q11-13	Developmental delay, intellectual disability, almond shaped eyes, inverted V-shaped upper lip, decreased muscle tone, obesity, small genitals, excessive appetite, hypopigmentation
Angelman syndrome	15q11-13	Developmental delay, intellectual disability, microcephaly, truncal ataxia/unstable gait, absence of speech, hyperactivity, spontaneous laughter, hypopigmentation, hypertonia
Williams syndrome	7q11.23	Cardiac anomalies (supravalvular aortic stenosis and pulmonic valvular stenosis), characteristic facies with periorbital puffiness, long philtrum and prominent lips, growth retardation, gregarious disposition, hoarse voice, hypocalcemia, hyperacusis, intellectual disability
Velocardiofacial syndrome	22q11.2	Facial dysmorphism (long broad nose with bulbous tip, hypertelorism, low set ears), palatal abnormalities (velopharyngeal incompetence, submucous cleft palate), hypocalcemia, developmental delay/intellectual disability, conotruncal cardiac defects (tetralogy of Fallot, truncus arteriosus), T-cell immunodeficiency
Miller-Dieker syndrome	17p13.3	Severe intellectual disability, developmental delay, seizures, hypotonia, feeding difficulties, distinctive facial features (prominent forehead, midface hypoplasia, small upturned nose, low-set and abnormally shaped ears, thick upper lip). Malformations include lissencephaly, renal, cardiac anomalies
Smith-Magenis syndrome	17p11.2	Mild to moderate intellectual disability, delayed speech and language skills, distinctive facial features, sleep disturbances, and behavioral problems, facial features (broad, square-shaped face with deep-set eyes, full cheeks, and a prominent lower jaw)
<b>Microduplication syndromes</b>		
Charcot-Marie-Tooth neuropathy 1A	17p12	Decreased reflexes, progressive distal muscular wasting, decreased muscle tone, sensory neuropathy
Potocki-Lupski syndrome	17p11.2	Hypotonia, failure to thrive, mental retardation, pervasive developmental disorders, and congenital anomalies
22q11.2 duplication syndrome	22q11.2	Developmental delay, intellectual disability, slow growth leading to short stature, hypotonia
Pelizaeus-Merzbacher disease	Xq21-22	Neuroregression, nystagmus, spastic quadriplegia, ataxia, and developmental delay

**BOX 3 Indications of karyotyping***Postnatal indications*

- Clinically apparent chromosomal disorder like Down syndrome, Patau syndrome, etc.
- Mental retardation
- Multiple malformations
- Disorders of sex development
- Primary amenorrhea or short stature in females
- Recurrent pregnancy losses
- Azoospermia in males
- X-linked recessive disorder manifesting in a female.

*Prenatal indications*

- Advanced maternal age
- Previous child with Down syndrome
- Soft markers on ultrasound
- Malformations in a fetus detected on prenatal ultrasonographic evaluation
- Parent is a carrier of balanced chromosomal abnormality.

**Fluorescence In Situ Hybridization**

The resolution of karyotyping is about 5 Mb. Hence, in order to detect abnormalities of lesser size, FISH is used. DNA probes are prepared in form of oligonucleotides which are complementary to the region of interest. These probes are labeled with fluorescent dye. A metaphase spread is prepared on a glass slide as described above. Both the probe and the DNA in metaphase spread are denatured by heating, followed by hybridization of probe onto the metaphase on slide. The DNA probe binds the complementary region in the metaphase. The location of probe binding on the metaphase can be visualized by a fluorescence microscope which uses light at a particular frequency and detects the emission of fluorescence (**Figs 6B and C**). Microdeletion leads to absence of probe binding. FISH is used for detection of microdeletions or microduplications, aneuploidy screening for rapid prenatal diagnosis, screening for copy number alterations and translocations in cancers, etc. (**Fig. 6B**). The resolution of FISH is about 1 Mb; hence abnormalities of few kilobases will not be detected by this method. However, FISH can look at one or a few regions at a time and clinical suspicion of a microdeletion or duplication syndrome is necessary before ordering FISH.

**Array Comparative Genomic Hybridization**

Microarray-based array CGH is a revolutionary platform that has been recently developed to screen entire genome for copy number abnormalities with resolution beyond the capacity of light

microscope (5–10 Mb). This technology was first developed as a research tool for the investigation of genomic alterations in cancer.

Array comparative genomic hybridization is based on the same principle of complementary DNA hybridization. Whole genomic DNA is labeled with fluorophores and used as probes that are hybridized onto nucleic acid targets on a microarray. Presence of deletion or duplication is inferred based on fluorescent intensity at each target site (**Fig. 6C**). The yield of karyotyping is about 5% in patients with intellectual disability. Use of array CGH increases the yield up to 20%. In view of this high detection rate, array CGH has been recommended as the first line of investigation in patients with intellectual disability, autism and multiple congenital anomalies.

**IN A NUTSHELL**

1. Chromosomal disorders form an important group of genetic disorders and are of various types. Majority present with mental retardation.
2. Karyotyping is the gold standard test to study the chromosomes.
3. Diagnosis of a chromosomal disorder is important for the management of patient, genetic counseling and prenatal diagnosis in future pregnancies.
4. Some patients with reproductive problems can have chromosomal abnormalities.
5. Molecular cytogenetic techniques help in studying chromosomes and the genome in greater detail.

## Chapter 2.5

# Management of Genetic Disorders and Genetic Counseling

Shubha R Phadke

Genetic disorders of chromosomal and monogenic etiologies are being diagnosed and many of them are being treated appropriately for many decades. However, tremendous developments in the field of genetics in recent times have resulted in a marked change in the approach to genetic disorders, leading to the establishment of the specialty of clinical genetics. With decrease in the infant mortality rate in India, the contribution of genetic disorders to morbidity and mortality in children is increasing. Genetic disorders involve every system of the body and clinical presentations of these disorders may be similar to many common *nongenetic* disorders. As new diagnostic techniques and new forms of treatments have now become available, it is imperative for clinicians to suspect genetic disorders in appropriate clinical situations, so that the fruits of research in the field of genetics reach patients with genetic disorders and their families. This chapter after briefly reviewing the traditional treatments of genetic disorders, will present an overview of newer treatments based on better understanding of molecular pathophysiology and the future possibilities.

## TRADITIONAL TREATMENTS

Many genetic diseases were being treated successfully even before their causative genes were identified. The treatments involved diet management, removal of offending agents, drugs, megavitamin therapies, surgical treatments and recently bone marrow and other organ transplantations. **Table 1** shows examples of such therapies which have shown very good results.

Many of these treatments are associated with very good outcome, though some require lifelong treatment. Bone marrow transplantation or stem cell therapy has been extended to many diseases other than hematological disorders such as lysosomal storage disorders. Some treatments are though effective in ameliorating symptoms, exact mechanisms of action are not clear. One example is efficacy of hydroxyurea in reducing the painful crisis in sickle cell disease. Surveillance for early diagnosis of treatable complications has been effective in many disorders especially familial cancers and cancer prone syndromes. Inborn errors of metabolism are an important group of genetic disorders for many of which considerable success in treatment has been reported over decades, even though for some disorders the treatment continues to be only partially successful.

## NEWER TREATMENTS

In addition to the treatable genetic disorders mentioned above and some more, many genetic disorders still do not have any therapeutic options other than supportive treatments and continue to have a poor prognosis. The treatments which have come into clinical practice over the last decade or more are discussed here.

### Growth Hormone Therapy for Turner Syndrome and Achondroplasia

Short stature is the major problem with Turner syndrome and achondroplasia, the problem being more severe with the latter. Availability of growth hormone as a drug has led to its use in various

genetic conditions with short stature. Consistent utility of growth hormone therapy in increasing the final height has been observed only in achondroplasia and Turner syndrome. The additional gain of height shown in various studies is 6–8 cm; the gain makes a significant difference to girls with Turner syndrome who usually have a height of a little less than 5 feet. For while for patients with achondroplasia this much gain may not be of much help in changing the quality of life and improving body image. Growth hormone therapy should preferably be started in early childhood and continued till completion of growth by fusion of epiphysis. The need for such a long-term treatment and cost of treatment and possible adverse effects need to be discussed with the child and the parents in the perspective of realistic gain of height, before starting the treatment.

### Bisphosphonates for Osteogenesis Imperfecta

Osteogenesis imperfecta is a common genetic bone disorder with great clinical variability, many cases being markedly deformed with severe physical disability. Bisphosphonates act by inhibiting osteoclast function of bone resorption. This drug treatment has found to be effective in reducing pain and frequency of fractures to a large extent in most of the cases causing marked change in the quality of life and reducing the extent of deformities. Even severe deforming type III cases with fractures at birth have been able to stand and walk if the treatment is started early. In the past few years, more than ten genes other than *COL1A1* and *COL1A2* have been identified to cause osteogenesis imperfecta. These genes are responsible for the autosomal recessive type of osteogenesis imperfecta and their proteins have important functions on post-translational modifications of collagen. There is limited information about the efficacy of bisphosphonates in these types of osteogenesis imperfecta. As bisphosphonate molecules get permanently deposited in bone tissue, some issues like duration of treatment and adverse effects with long-term therapy still remain unresolved.

### Therapies for Lysosomal Storage Disorders

Enzyme replacement therapy (ERT) for lysosomal storage disorders is the great success story which has created hope for other metabolic disorders and many other genetic disorders in general, in the 21st century. Providing deficient enzyme as a treatment was being tried for a long time, but became successful only when targeting of the enzyme to its intracellular location of action was achieved by attaching the mannose 6-phosphate molecule to the recombinant enzyme. This allows the enzyme to enter the cell through the mannose 6-phosphate receptors on the cell surface. With this strategy, successful enzyme replacement therapy came into clinical practice for type I Gaucher disease in 1991. ERTs for other diseases got approval from 2001 onwards. At present ERTs are available for mucopolysaccharidosis (MPS) I, MPS II, MPS IV, MPS VI, Pompe disease and Fabry disease, with very impressive results. The skin and joint changes and organomegaly decrease in MPS, while in Gaucher disease there is normalization of the hematological profile, with reduction in the size of the liver and the spleen. The results of ERT for Pompe are variable; cases started on ERT early in the course of the disease show marked improvement, but the outcome may not be good if ERT is started in an advanced stage. For this reason, some countries have included Pompe disease in the newborn screening program and the babies put on ERT pre-symptomatically have been found to achieve normal motor milestones with no cardiac involvement. Fabry disease is difficult to diagnose due to nonspecific symptoms like neuralgic pains in limbs and lack of clinical signs in many cases. Most of the cases develop stroke, renal failure or cardiac symptoms by young adulthood. It is responsible for 1% of cases with end-stage renal disease. As ERT can reduce the incapacitating limb

**Table 1** Successful traditional therapies for genetic disorders

Abbreviations: G6PD, glucose-6-phosphate dehydrogenase deficiency; BMT, bone marrow transplantation.

pains and also reduce the risk of life-threatening complications, it is important to suspect it in appropriate clinical situations even if the characteristic angiofibromas are absent on the skin. Asymptomatic relatives of a confirmed case of this X-linked disease including carrier females should be evaluated for pre-symptomatic diagnosis. Similar high level of suspicion is necessary for diagnosing patients with Pompe disease and milder forms of MPS, who will be benefited by ERT. It needs to be mentioned that ERT is still ineffective for the neurological effects of the disease as it cannot cross the blood brain barrier. For MPS cases with neurological involvement bone marrow

transplantation before significant neurological involvement may arrest further progression of the neurological component as well.

Other than ERT, substrate reduction therapy is another form of therapy available for those cases of lysosomal storage disorders that have some residual enzyme activity. This is aimed at blocking the synthesis of glycosphingolipids by blocking glucosylceramide synthase. Thus, the deposition of sphingolipids responsible for the pathogenesis of the disease is reduced. The orally available molecule miglustat is effective in many cases of Gaucher disease type I and Niemann-Pick disease type C.

### Fetal Therapy

Many genetic disorders can now be easily diagnosed prenatally by invasive or non-invasive methods. Effective treatments for fetal tachyarrhythmia and corticosteroid treatment for congenital adrenal hyperplasia (started immediately after confirmation of pregnancy to prevent genital ambiguity) are being practiced. Interventions for hydrocephalus and obstructive uropathy have been shown to be feasible, but have limited utility as there is not much difference in the outcomes of cases with pre- and postnatal treatment. Open surgery for meningocele before 26 weeks of pregnancy is being done at a few centers and has been found to have a definitely better outcome as regards to the neurological outcome. However, invasive nature of this procedure poses risks, both to the fetus and the mother. Stem cell therapy of the fetus is still in the research phase, but has been tried for hematological disorders like thalassemia and immunodeficiency disorders.

### POST GENOME ERA SUCCESSES

The Human Genome Project led to the identification of causative genes for many monogenic disorders, development of many molecular techniques used in gene mapping and the understanding of molecular pathogenesis of various diseases. This, in turn, led to the application of new molecules and strategies to the treatment of genetic disorders. These therapeutic strategies are more specific to the genetic defect and better targeted to the pathology. Some examples are discussed here.

#### Ivacaftor for Cystic Fibrosis

Cystic fibrosis is caused by mutations in the *CFTR* (cystic fibrosis transmembrane conductance regulator) gene. The protein functions as a gated anion channel to increase conductance for certain ions like chloride. Hundreds of mutations have been identified in the *CFTR* gene. In 2012, ivacaftor was approved for treatment of patients of cystic fibrosis with a specific mutation, i.e. G551D which affects the gating function at the cell surface of the *CFTR* protein. This molecule was selected from more than 2 lac drug molecules due to its ability to potentiate the activity of *CFTR*. Within a short span of a few years, studies on cell lines and human patients have confirmed the beneficial effect of the drug. The drug is now approved for cases with the specific mutation which accounts for a small proportion of cases of cystic fibrosis and studies on its efficacy on other types of *CFTR* mutations are ongoing. This is an example of personalized medicine, but the cost is exorbitant at present. It is important to mention here that the Cystic Fibrosis Foundation has contributed to the development of the drug.

#### Sapropterin for Phenylketonuria (PKU)

Phenylketonuria caused by the deficiency of phenylalanine hydroxylase has been treated for more than six decades with special diets free of phenylalanine. Lifelong strict diet control is a challenge to the patient and the family. Tetrahydrobiopterin is a cofactor in the enzymatic conversion of phenylalanine to tyrosine by phenylalanine hydroxylase, which is deficient in PKU. Some scientists in 1999 observed that oral tetrahydrobiopterin intake reduces the phenylalanine level in some patients with mildly raised levels of phenylalanine even without altering the diet; this was confirmed later by other studies. This has led to the development of sapropterin hydrochloride, a drug approved in the US and Europe for management of PKU. It reduces or eliminates the need for dietary therapy in some cases of PKU. It has now been found that the efficacy of sapropterin is not due to its effect on the metabolism of phenylalanine, but due to its efficacy as a chaperon molecule. It helps a misfolded protein to gain some of its function and hence is effective in patients with mutations which lead to misfolding of the protein. This chaperon like activity of sapropterin may also make it

useful in other diseases caused by mutations leading to misfolding of proteins.

#### Losartan for Marfan Syndrome

Marfan syndrome is caused by mutations in the *FBN1* gene which encodes for fibrillin protein, which is a component of the connective tissue. Weakness of connective tissue was considered to explain the cardiac, eye and other connective tissue abnormalities in patients with Marfan syndrome. It was later observed that mutation in the *FBN1* gene leads to activation of the transforming growth factor (TGF) beta pathway and manipulation at this level seemed easy as the already approved drug losartan was known to inhibit the TGF beta pathway. Use of losartan in mice with Marfan syndrome showed very impressive results with total absence of the eye and heart phenotype. Recently, human trials have convincingly shown that losartan prevents dilatation of the aortic ring. This is a successful and easy treatment which works by modifying the downstream pathway rather than correcting the gene or giving the deficient protein.

Similar therapies based on understanding of pathways are also being explored in other groups of disorders caused by disturbances of molecular pathways. An example is the RASopathies, a group of clinically similar disorders (Noonan, Costello, LEOPARD and cardiofaciocutaneous syndromes) caused by mutations in any of the genes in the RAS-MAPK pathway (*BRAF*, *HRAS*, *KRAS*, *PTEN11*, *SPRED 1*, etc.). This pathway is well studied and is an attractive target for inhibition using small molecules used to treat cancers.

### PHARMACOGENOMICS

Genetic defects not only cause diseases but they also determine the dose requirement and toxicity of drugs prescribed for nongenetic disorders and hence this aspect also needs to be considered as a part of genetics and treatment. Hemolysis due to certain drugs in individuals with G6PD (Glucose-6 phosphate dehydrogenase) deficiency is a well known example of the varying effects of drugs in different individuals. Genes affecting the dose requirement for various drugs and susceptibility to the adverse effects are being studied. Nucleotide variations in Cytochrome P450 and *VKORC1* genes have been identified to contribute to variability of the required dosage for the coumarin group of drugs. Though genetic variations account for only a part of the drug dose variability, the US Food and Drug Administration (FDA) has approved the test for genotyping and the drug label also mentions that the genotype information can be used for initial dose selection. Another example of a strong correlation between genetic variation and drug toxicity is that of anticancer drugs like 6-Mercaptopurine, where the level of the drug metabolizing enzyme thiopurine S-methyltransferase (TPMT) is governed by polymorphisms in the *TPMT* gene. With techniques like whole genome sequencing and SNP microarray to look at the whole genome in one go, more associations of genotypes with drug toxicity are being explored and medicine may be marching towards personalized medicine with lower risks of adverse effects.

### INTERESTING STRATEGIES IN THE PIPELINE

As has been highlighted by successful new therapies, better understanding of disease pathologies at the molecular level and the ability to manipulate the genome is likely to transform the therapeutic options for genetic disorders in the 21st century. Many interesting and logical strategies for monogenic disorders are being conceptualized and tried in laboratories and a few have also been tried in patients. Very attractive results have been observed in the experiments in cell lines and sometimes in animal models. However, in spite of extensive efforts of scientists, only a very few

treatment modalities have reached the stage of clinical trials. Many new therapies in the pipeline may not have shown clinically significant outcomes yet, but promises for the future are evident. Some strategies and drugs in various stages of research are listed in **Table 2**. Use of small RNA molecules complementary the RNA transcript those interfere with its abnormal function or abnormal protein formation has been showing a great promise as a treatment of choice for not only monogenic diseases like triplet repeat disorders and Duchenne muscular dystrophy but also for cancers and viral infections.

After experiments on cell line, trials in animal models become very important in development of any therapeutic strategy. Naturally occurring or artificially created (by knocking down a gene) animal models are available for research for many disorders like Fragile X syndrome, Huntington chorea, Duchenne muscular dystrophy, etc. Their contribution to the drug developments is very important.

## GENE THERAPY STORY: SUCCESS AND HURDLES TO CROSS

With development of the ability to manipulate the gene, correction of genetic defects at DNA level appeared the most logical treatment. The first gene therapy was attempted for beta thalassemia in 1980, but was not successful. First success for gene therapy was recorded in a girl with immunodeficiency due to adenosine deaminase deficiency, but she was continually receiving the recombinant enzyme as well, raising doubts about the efficacy of gene therapy. First long-term success with gene therapy for X-linked immunodeficiency for more than 10 patients was documented by a French group. Two of the patients however, developed a leukemia-like disease, confirming the risk of malignancy due to gene therapy. Another important setback to gene therapy trials was the death of Jesse Gelsinger who participated in a gene therapy trial for ornithine transcarbamylase deficiency (OTC). He died on the fourth day of gene therapy probably due to an immune reaction to the adenovirus used as a vector to carry the gene. Till date more than 1,800 gene therapy

trials have been completed or are ongoing under strict guidelines and supervision of ethics committees.

The best vector to transfer the gene of interest is currently an important limitation. The best vector should be harmless, should be able to carry a large sized gene to the target cells, get incorporated into the nuclear DNA without disturbing any important gene, and should be able to produce the necessary gene product in adequate amounts and over a long period. At present most gene therapy protocols use viral vectors and the possibility that they may become infectious, carcinogenic or cause immune reaction continues to pose a big threat. Recent studies have tried liposomes or gene packed in lipids to avoid the use of viral vectors. However, the search for the ideal vector continues.

Of all gene therapy trials at present, only 10% are being done for single gene disorders. Though a complete cure has not been achieved, clinically significant successes are being reported for some diseases such as Leber congenital amaurosis caused due to *RP65* gene mutations and hemophilia B. Diseases like hemophilia B, where a small amount of the gene product is sufficient for clinical efficacy, are good candidates for gene therapy. Diseases like thalassemia need a regulated expression of the gene and hence are more challenging. For diseases like Duchenne muscular dystrophy the target tissue is big and gene expression in all muscle cells is necessary to be clinically effective. The other challenge for Duchenne muscular dystrophy is the very large size of the gene; a carrier vector for transporting such a large gene is not available. To overcome this, a minigene construct containing only the very important regions of the dystrophin gene has been tried with limited success. Another strategy called exon skipping therapy is being tried for Duchenne muscular dystrophy. It involves the use of small oligonucleotide segments to block the expression of the defective part of the gene and restore the reading frame of the gene sequence, so that the gene product contains the normal sequence of amino acids before and after the defect. Exon skipping therapy has shown some benefit in Phase II trials and Phase III trials are underway. Though not completed yet, positive results are being reported for gene therapy trials for eye diseases like retinitis pigmentosa, Stargardt disease, age related macular degeneration

**Table 2** Novel treatment strategies for genetic disorders, in various stages of experimentation and trial

Disease	Treatment strategy	Drug	Comment
Duchenne muscular dystrophy	Exon skipping	Using antisense oligonucleotides	Phase II, III trials
	Read through stop codon	PTC124* (Ataluren)	Phase II Phase III trial for cystic fibrosis
	Upregulation of Utrophin	SMT C1100-A small molecule – moderator of utrophin expression	Animal models
	Gene therapy	Insertion of minigene With important exons of dystrophin gene	Animal models, cell lines
Spinal muscular atrophy	Modulation of alternate splicing of <i>SMN 2</i> gene to increase its expression	Antisense RNA	Animal model
Fragile-X syndrome	mGluR-5 antagonist	MPEP	Animal model
Fragile-X tremor ataxia syndrome	Silencing by small interfering RNA (siRNA)	Antisense RNA	Also being tried in many disorders like myotonic dystrophy, SCA 8, and cancers
Rett syndrome	Increasing BDNF (Brain-derived neurotrophic factor)	Ampakines	Phase II
	IGF1 (Insulin like growth factor)	IGF 1	Phase I
Achondroplasia	Suppressing activated fibroblast growth factor receptor 3 (FGFR3) signaling	Meclozine, an antihistaminic	Cell lines

Note: \*- also tried in Cystic fibrosis, Rett syndrome and MPS I due to stop codon mutations, MPEP – 2-Methyl 6-phenylethynyl pyridine.

and choroideremia. Gene therapy trials are also underway for cystic fibrosis, Niemann-Pick disease, X-linked adrenoleukodystrophy and hyperlipidemias.

In addition to monogenic disorders gene therapy trials are also being done for cardiovascular diseases, HIV, autoimmune diseases and for cancers. Products of gene therapy have been approved for patients in China and Europe. The *Gene Pill* might become a treatment for every genetic and many nongenetic diseases in this century, but *when* is a question that only time can answer.

## STEM CELL THERAPY AND REGENERATIVE MEDICINE

Transplantation of hematopoietic stem cells from the bone marrow has been an accepted therapy for some genetic hematological disorders and is being used for patients. But the number of diseases for which this option is effective is still small. A lot of basic information about stem cells is becoming available including their sources and ubiquitous presence. In research settings, trials using stem cells from the peripheral blood or the umbilical cord, for various genetic disorders as well as stroke, ischemic heart disease, spinal cord injury, etc. are being done. Though stem cells take part in the normal regenerative and repair processes of the body, there is no convincing, unambiguous proven benefit of such stem cell therapy. Available data does not show any success of stem cell therapy for muscular dystrophies, developmental disabilities like intellectual disability, autism and neurodegenerative disorders. Success has been achieved in transforming human pluripotent cells into disease specific cells. The ability to transform the human pluripotent cells into target cells like pancreatic cells or neurons for use of transplantation has opened up new avenues. This is an important step towards obtaining an unlimited source of cells and may be considered a major step in the direction of regenerative medicine. At present no developed country has approved such type of stem cell therapy for patients.

### Umbilical Cord Blood Banking

Umbilical cord blood is a very good source of hematopoietic stem cells and can be used as an option for human leukocyte antigen (HLA)-matched siblings or unrelated recipients for the treatment of hematological disorders like thalassemia major, aplastic anemia or immunodeficiency disorders. Hence umbilical cord banking has come into practice. Cord blood banking for personal use is not recommended unless there is a family member affected with one of the above mentioned disorders for which stem cell therapy is an accepted option. For a child to need his or her cord blood stem cells in the future is a remote possibility. Stored cord blood of an individual is of no use for the treatment of genetic disorders in the same individual, as the stem cells also have the same genetic defect. Public banking is a good option and the stored cord blood can be used for the needy person with a good HLA match.

## EFFECT OF DIAGNOSTIC ADVANCES ON TREATMENT OUTCOMES

The first and the most important requisite for effective treatment is accurate diagnosis. Tremendous advances have been made in DNA based diagnostics for genetic disorders. Causative genes for more than two-thirds of the 6,000 odd known monogenic disorders have been identified. The technical hurdle of large sizes of genes and genetic heterogeneity has been crossed by next generation high throughput techniques which can sequence multiple genes or the whole genome at a time. Sequencing coding regions (exons) of all genes (termed as the exome) is used as a diagnostic test for undiagnosed disorders suspected to have a genetic etiology. In 2012, for the first time, treatment based on diagnosis obtained

by exome sequencing was done. This was for a young child with Crohn disease-like illness. He was extensively investigated for immune deficiency disorders; but without any success. His exome sequencing identified a sequence variation in an apoptosis inhibitor gene which explained the clinical picture. Based on the diagnosis bone marrow transplantation was done and the child was cured. Similarly in a patient with clinical features of hereditary spastic paraparesis exome sequencing identified a mutation in the gene causing dopa-responsive dystonia. The patient improved markedly with treatment with L-dopa. Such types of diagnostic surprises leading to access to curative treatments is becoming a part of clinical practice, thanks to next generation sequencing. Hence, the contribution of diagnostic techniques to the progress in the management of genetic diseases needs to be emphasized.

Newborn screening has been in patient care for the last five decades. Over the last two decades there has been a number of additions to the diseases included in the newborn screening programs, the latest addition being severe combined immunodeficiency (SCID). The treatment of SCID is bone marrow transplantation which has very good success if done before the onset of symptoms; i.e., before contracting infections. This early pre-symptomatic diagnosis can only be achieved by newborn screening. The progress in diagnosis and management will keep on going hand in hand.

Sequencing the whole genome or whole exome (all coding sequences) has been done for thousands of individuals by now and is possible to be done from the sample taken on filter paper for newborn screening. It has also been done from free fetal DNA (ffDNA) in maternal plasma. All monogenic disorders hence can be diagnosed at or before birth. As more and more disorders become treatable, the pre-symptomatic diagnosis at birth may be the first step to a long and healthy life in future.

## GENETIC COUNSELING

The 21st century holds many promises for genetic disorders. But still many genetic diseases are untreatable, handicapping or associated with morbidity and mortality. The other implication of genetic diseases is the possibility of recurrence in the family. This makes genetic counseling an integral part of the management of genetic disorders.

### Definition

The American Society of Human Genetics has defined genetic counseling as *"a communicative process which deals with human problems associated with the occurrence and/or recurrence of a genetic disorder in a family"*. This process involves an attempt by one or more appropriately trained persons to help an individual or a family to: (i) comprehend the medical facts, including the diagnosis, probable course of the disorder and available management; (ii) understand the manner in which heredity contributes to the disorder, and the risk of recurrence in the family; (iii) understand the alternatives for dealing with the risk of occurrence or recurrence; (iv) choose a course of action which seems to them appropriate in view of this risk, their family goals, ethical and religious standards and to act in accordance with the decision; and (v) make the best possible adjustment to the disorder in an affected family member and/or to the risk of recurrence of that disorder.

This makes one understand that the aim of genetic counseling is to educate the family about the genetic disorder and help them to cope with the problem and the risk of recurrence of the disorder.

### Principles and Steps

Genetic counseling is a communication process of management but based on latest scientific and medical knowledge of the

disease. So the process has to be nondirective as against other situations involved in medical advice. Accurate diagnosis, complete family history, latest review of the disease in concern and communication of the information in simple and local language are the steps of genetic counseling. The information provided in the genetic counseling session should be simple and provided to the concerned family members preferably together. The privacy, emotional complexities, socio-economic and religious background and expectations of the family should be taken into consideration to make genetic counseling a success.

A person who seeks genetic counseling is called a consultand or *counselee*, and the person who gives the advice is called the counselor. In association with a medical specialist, persons from various backgrounds such as nursing, sociology, psychology or genetics can be trained as genetic counselors.

### Indications for Genetic Counseling

The following clinical presentations indicate the need for referral to a clinical geneticist and genetic counseling:

- *Congenital malformations* Lethal or nonlethal, isolated or multiple, prenatal or postnatal.
- Unexplained still births/perinatal deaths with or without malformation.
- Developmental delay or mental retardation with or without malformations, facial dysmorphism and/or neurological deficit.
- Neurodegenerative diseases presenting as focal neurological deficit, ataxia, spasticity, hypotonia, seizures or psychomotor regression.
- Myopathies and muscular dystrophies.
- A neonate or an infant with acute sickness, failure to thrive or recurrent episodes of vomiting, acidosis and/or convulsions.
- Ambiguous genitalia or abnormalities of sexual development like primary amenorrhea and delayed puberty.
- Infertility and poor obstetric history like recurrent spontaneous abortions and fetal losses.
- Proportionate or disproportionate short stature.
- Childhood deafness.
- Known monogenic disorders like thalassemia, Wilson disease, hemophilia A, MPS, etc.
- Down syndrome and other chromosomal disorders.
- Familial cancers or cancer prone disorders.
- Relatives of an individual having a structural abnormality of a chromosome or chromosomes.
- Any unusual disease of the skin, eyes, bones or unusual facial features.
- Any disease which is familial.
- Exposure to a known or possible teratogen during pregnancy.
- Consanguineous marriage.
- Advanced maternal age.
- Carrier of a genetic disorder.
- Positive screening test for a genetic disorder.

### PRENATAL DIAGNOSIS

Many a times, helping the family to take reproductive decisions and organizing prenatal diagnosis is the aim of genetic counseling. Availability of invasive and noninvasive diagnostic tests makes things easier for the family and the counselor. A variety of tissues can be collected from the fetus for chromosomal, DNA and biochemical analysis. These include chorionic villi (at 11–12 weeks of gestation) and amniotic fluid (at 16–20 weeks of gestation). Rarely, fetal skin, muscle, liver biopsy or blood sample may be collected for biochemical or tissue analysis. For DNA-based prenatal diagnosis of monogenic disorders mutation detection of the proband or of the carrier parent or parents in the family is

a prerequisite. Analysis of fetal DNA from mother's blood has become technically possible and can be used for fetal Rh typing, single gene disorders and aneuploidy detection. Pre-implantation diagnosis is a good option for families who do not approve of termination of pregnancy.

High resolution ultrasonography can detect a number of structural malformations of the central nervous system, gut, kidneys, limbs, spine and heart. Detection of associated malformations and chromosomal analysis is useful for providing counseling in a case with prenatally detected malformation. But for counseling regarding next pregnancy, examination of the baby or fetus after delivery or termination (fetal autopsy) is important, because in 30–40% cases associated malformations may be missed or may not be detectable on ultrasonography.

### FUTURE AHEAD

Medicine has entered the molecular era. There is a paradigm shift in the diagnosis and management of genetic disorders. Gene therapy may or may not become a reality for all disorders; many new pathway-based drugs and other methods to modify translation and transcription of target genes or modifier genes may open up new avenues for genetic disorders. Success of ERT for lysosomal storage disorders and ivacaftor for cystic fibrosis has also brought another problem to the forefront. This problem is the exorbitant costs of these new treatments due to the heavy cost of research which goes into the development of new therapy. The scientists and the society have to take up this problem.

When one peeps into the future, the other possibility that comes to mind is the treatment of the embryo. Testing of the embryo by testing fDNA in maternal plasma is now possible for chromosomal as well as single gene disorders. Scientists have successfully sequenced the exome of fetus from fDNA, making identification of any inherited or de novo mutations in the fetus possible. A group of scientists have even shown that the extra copy of chromosome 21 in cell lines from a Down syndrome child can be silenced and the normal diploid functional genome can be restored. This makes one dream of the possibility of diagnosis and treatment of embryos and fetuses with genetic disorders.

### IN A NUTSHELL

1. For all cases in which a genetic disorder is diagnosed or suspected, complete evaluation of the affected individual and genetic investigations are important.
2. Latest information about available treatments is the responsibility of a clinician. Missing a diagnosis of a treatable disorders will be a misfortune for the patient and may be considered negligence on the part of the doctor.
3. Genetic counseling is an integral part of the management of a case with a genetic disorder. It is the responsibility of the primary care physician to suspect cases with a probable genetic disorder and refer them to a clinical genetics center. As clinical geneticists are few in number, pediatricians, obstetricians and physicians may have to take up the responsibility of providing diagnosis and counseling for common genetic disorders.
4. New treatment strategies based on the understanding of molecular pathology have become available for some disorders like cystic fibrosis, Marfan syndrome and lysosomal storage disorders and many more in pipeline are showing promises.
5. Gene therapy expected to find cure for all genetic diseases has been successful in immunodeficiency disorder, but many hurdles need to be crossed till it becomes a reality for many other genetic disorders and cancers.

## Chapter 2.6

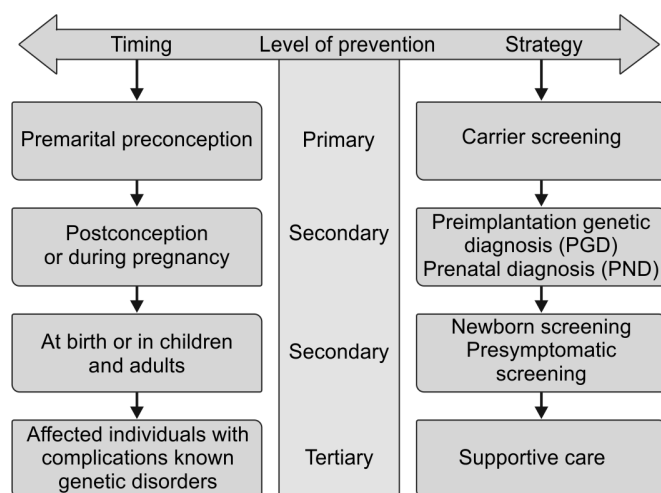

# Prevention of Genetic Disorders

Neerja Gupta, Madhulika Kabra

*An ounce of prevention is worth a pound of cure*—a quote by Benjamin Franklin correctly stresses the importance of prevention which plays a major role in the management of genetic disorders. Several single-gene, chromosomal and multifactorial disorders occur at a high frequency in every population. Over years, better understanding of the pathophysiological mechanisms of genetic disorders has paved way for several newer therapies for various genetic disorders, however, their use does not lead to complete clinical cure for many and is available for a limited number of disorders only. Moreover, the cost of therapy involved in such therapies, the associated morbidity of the disorder and the poor quality of life for the family as a whole, prevention is the focus for all genetic disorders. The prevention of genetic disorders can be done at three levels:

1. **Primary prevention** To prevent the occurrence of the disease, i.e., preventing birth of an affected child. It reduces the incidence and prevalence of a genetic disorder.
2. **Secondary prevention** To prevent clinical manifestations in affected individuals by appropriate early intervention such as by early detection through prenatal diagnosis, newborn screening and presymptomatic screening. It basically detects the disease at a preclinical stage and decreases or ameliorates its severity. It also targets to prevent the recurrence of disease in a particular family by providing high doses of vitamins, such as folic acid, to prevent neural tube defects.
3. **Tertiary prevention** To provide better care and rehabilitation to the patients with disease. It basically means providing best supportive care to the affected patients with various chronic genetic disorders.

The different levels of prevention pass through various life stages for ultimately providing a good quality of life to the individual, family and society at large. **Figure 1** depicts the levels of prevention at different life stages using different strategies.

**Figure 1** Strategies for prevention of genetic disorders

## COMPONENTS OF PREVENTION PROGRAM FOR GENETIC DISORDERS

The three important components of an effective prevention program are awareness, screening and genetic counseling (**Fig. 2**). Increased awareness amongst policy makers, health professionals, paramedics, social health workers and the community requires involvement of mass communication and media. The next step is providing services for various screening tests for genetic disorders. A genetic screening test has to be accompanied by appropriate pretest and post-test counseling. An effective prevention program at various levels, not only reduces the incidence of that particular disorder, morbidity, the psychological and social trauma associated with rearing individuals with these disorders but also gives an opportunity to live with pride and independence to these individuals. **Figure 3** demonstrates the Cyprus model wherein timely introduction of a comprehensive screening program in 1970s led to massive reduction in the incidence of  $\beta$ -thalassemia by 1990s. The decisions to adopt any particular prevention program relies upon the burden of the disorders, ethnic distribution of the disorder, attitudes toward genetic screening, acceptability of termination based upon the religious background, resources and political will. The success of any effective prevention program can be judged on the basis of reduction in the incidence of that particular disorder.

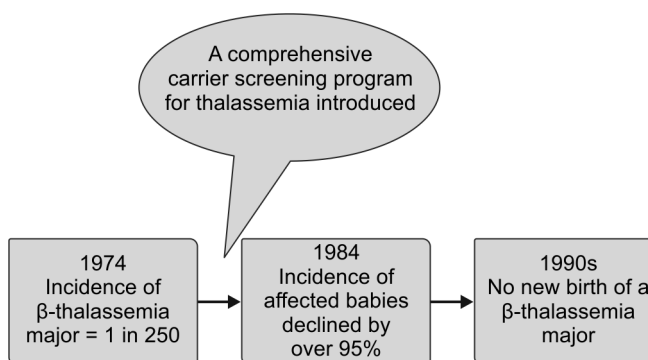

Next section focuses on the strategies that can be used at various levels of prevention for genetic disorders. **Table 1** briefly outlines the various strategies.

## PRIMARY PREVENTION

The disorders most amenable to primary prevention are birth defects such as neural tube defects and chromosomal disorders. Prevention of birth defects is possible through appropriate maternal nutrition, providing supplementation or fortification with folic acid and adequate control of maternal diabetes. A landmark randomized double-blind prevention trial on prevention of neural tube defect by Medical Research Council Vitamin Study Research

**Figure 2** Components of prevention programs

**Figure 3** Cyprus as a success model for effective prevention program for thalassemia

**Table 1** Strategies for primary, secondary and tertiary prevention of genetic disorders

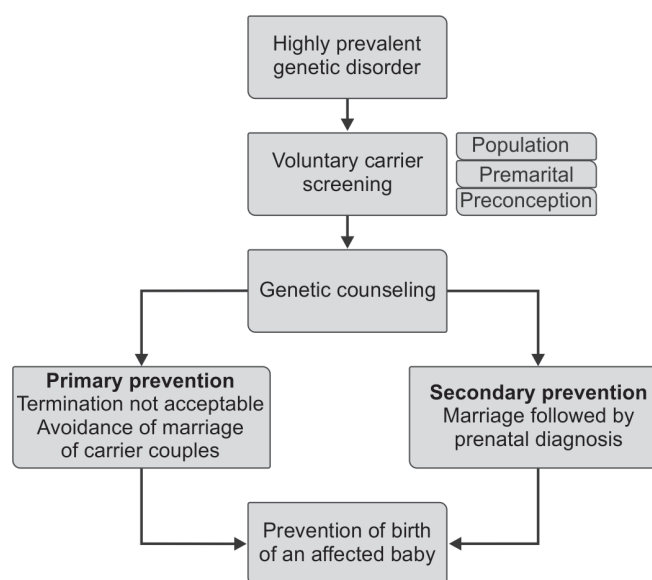

<i>Suggested primary prevention package (preconception and premarital)</i>	<i>Suggested secondary prevention package (pregnancy, neonate, child, and adults)</i>	<i>Suggested tertiary prevention package (neonate, child, and adults)</i>
<ul style="list-style-type: none"> <li>Improved maternal nutrition and folic acid supplementation 400 µg daily</li> <li>Universal rubella immunization</li> <li>Family planning between reproductive age of 20–35 years</li> <li>Identification of high-risk genetic factors and patients, and families (carrier screening) for appropriate genetic counseling at primary health care</li> <li>Control of maternal health and obesity associated conditions such as diabetes</li> <li>Raise awareness about effect of maternal drugs for maternal illnesses on fetuses during pregnancy</li> <li>Identification of families at high-risk of genetic disorders by family history</li> </ul>	<ul style="list-style-type: none"> <li>Control of maternal health associated conditions such as diabetes</li> <li>Shift to safer drugs for maternal illnesses during pregnancy</li> <li>Carrier screening and genetic counseling for common genetic disorders like thalassemia</li> <li>Antenatal biochemical screening for chromosomal and neural tube defects</li> <li>Prenatal diagnosis of malformations by ultrasonography followed by counseling</li> <li>Newborn screening for metabolic disorders and birth defects</li> <li>Presymptomatic screening for at risk family members if medical intervention is possible and feasible</li> </ul>	<ul style="list-style-type: none"> <li>Improved access to medical facilities for children with chronic genetic disorders</li> <li>Multidisciplinary, supportive care</li> <li>Monitoring growth and development of child, complications anticipated for any particular genetic disorders</li> <li>Psychosocial support of affected individuals and their families</li> </ul>

Group in 1991 across 11 countries, demonstrated a 72% protective effect of folic acid in women at high risk of having a pregnancy with a neural tube defect, because of a previous affected pregnancy. Universal rubella immunization and avoidance of teratogenic drugs are other important steps toward primary prevention of birth defects. Avoidance of pregnancy during advanced maternal age can avoid common chromosomal disorders, such as Down syndrome, to some extent, but this is not a practical feasible strategy in the present era. More so majority of babies with Down syndrome in India are born to young mothers. A preconception screening program involving modifiable risk factors, like screening for maternal diabetes, thyroid, syphilis, rubella immunization and folic acid supplementation, is actually lacking in our country as a standard of care even in the majority of big hospitals.

*Primary prevention by carrier screening* for highly prevalent genetic disorders (e.g.,  $\beta$ -thalassemia) in a particular high-risk community comes under this category. Carrier screening during premarital period is a very sensitive issue and should be preceded by appropriate nondirective pretest counseling. Testing should be strictly voluntary as it may avoid marriage of at risk couples. This strategy is particularly useful when abortion is not acceptable, but may not be acceptable for some families as it is difficult to influence personal issues like marriage and reproduction. The usual strategy for any carrier screening program is depicted in **Figure 4**. The objective is to identify all the individuals who themselves are healthy but at risk of having children with a severe autosomal recessive or X-linked disorder. Criteria for carrier screening are given in **Box 1**.

#### BOX 1 Criteria for carrier screening

- Disease should be an important health problem and should be severe but amenable to prevention
- Screening is directed toward high-risk population
- The test should be safe, inexpensive, easily available and should have high sensitivity and specificity
- The screening program should be socially, ethically and morally acceptable to the target population
- Participation in the screening program must be entirely voluntary with prior informed consent and confidentiality must be ensured
- Detailed information about that particular disorder and a pretest and post-test counseling should be available
- At risk carrier couple should have access to various reproductive options (prenatal diagnosis, treatment).

**Figure 4** Strategy for a carrier screening program

The timing of any carrier screening program is program specific. It could either be at population level, during premarital period or can be done preconceptionally. **Table 2** provides the carrier frequency of various genetic disorders in different ethnic groups.

#### Target Disorders for Carrier Screening in Indian Context

Although exact prevalence of most disorder is not known in India due to lack of any registry; a large data available about hemoglobinopathies support it to be a major prevalent group of disorders in our population. The carrier rate of  $\beta$ -thalassemia is 5–15% amongst the Sindhis and Punjabis. Based on various surveys, prevalence of sickle gene is found to vary between 0 and 35% in various regions of our country, being highest in central India. With the current population estimate and birth, it is estimated that over 42 million are carriers and over 12,000 infants are born each year with a major and clinical significant hemoglobinopathy.

**Table 2** Frequency of selected disorders requiring carrier screening in various ethnic groups

Disorder	Ethnic group	Carrier frequency
Alpha thalassemia	Southeast Asians and Chinese	1/25
Beta thalassemia	India, Greek/Italian, Cyprus Sardinia	1/25–1/30
Cystic fibrosis	Northern Europeans	1/25
Phenylketonuria	Northern Europeans	1/50
Sickle cell disease	African-American Central India Specific tribal population	1/12 ~1/15
Spinal muscular atrophy	Asian	1/30
Tay-Sachs disease	Ashkenazi Jews	1/30

Few other disorders, such as megalencephalic leukodystrophy and spinocerebellar ataxia type 12, are frequent genetic disorders in Agarwal community. Other prevalent genetic disorders are glucose-6-phosphate dehydrogenase deficiency, cystic fibrosis, spinal muscular atrophy, Tay-Sachs disease, Duchenne muscular dystrophy, fragile X syndrome and hemophilia.

## SECONDARY PREVENTION

Secondary prevention focuses on avoiding the birth of affected fetus [prenatal screening, prenatal diagnosis and preimplantation genetic diagnosis (PGD)], early detection of the disorders, appropriate medical intervention to minimize the manifestations (newborn screening) or detecting the genetic predisposition for a condition with onset in the later life (presymptomatic screening).

### Prenatal Screening

Objective of the prenatal screening and diagnosis is to identify the mothers at high risk of having an affected fetus with a genetic disease. This includes biochemical screening and evaluation by ultrasonography; noninvasive prenatal testing. Once the fetus is found to be affected, option for termination of pregnancy (the legal age of which in India is 20 weeks) or prepare themselves psychologically for adequate management and care of affected child after birth.

*Indications for prenatal screening and diagnosis are:*

- Advanced maternal age
- Previous child with any chromosomal abnormality
- Previous child with a common single-gene disorder like thalassemia, cystic fibrosis, Duchenne muscular dystrophy, spinal muscular atrophy or multifactorial disorder like neural tube defects, cleft lip/palate
- Abnormal findings in ultrasonographic evaluation of the fetus
- Abnormal maternal screening
- Maternal infection
- Teratogen exposure.

### Neural Tube Defects

Maternal serum  $\alpha$ -fetoprotein (AFP) levels are measured at 16–18 weeks of gestation. A cut-off of more than 2.5 multiple of the median detects more than 90% cases of anencephaly and 80% cases of open spina bifida. Though the specificity of the test is not very high, AFP levels are increased in impending abortion, twin pregnancy, and exomphalos. The test is used widely and has led to a striking decline in the incidence of open neural tube defect.

## Down Syndrome

**Biochemical screening** Antenatal screening is a useful test that detects the likelihood of baby being born with Down syndrome. The American College of Obstetrics and Gynecology and the American College of Medical Genetics and Genomics (ACMG) recommend antenatal screening for women of all age groups. Antenatal screening can be done either during first trimester or second trimester depending upon the availability of the test and the timing of the first visit by a pregnant lady. First trimester screening incorporates maternal age risk, nuchal translucency measurement by ultrasonography along with maternal serum beta human chorionic gonadotropin and pregnancy-associated plasma protein A levels between 11 to 13 completed weeks. The detection rate of first trimester screen varies between 80% and 82% at a false positive rate of 3%. Amongst the second trimester screening, quadruple test is preferred to triple test. It includes maternal age risk and estimation of maternal serum human chorionic gonadotropin, unconjugated estriol, AFP and inhibin A levels between 15 weeks and 19 weeks. If combined with 18 weeks anomaly scan, the detection rate is approximately 80% at a false positive rate of 3%. If the risk for Down syndrome exceeds the cut off of 1:250, prenatal diagnosis either by chorionic villi sampling at 11–12 weeks or amniocentesis 16–18 weeks may be offered to examine the fetal chromosomes. The results are usually available in 2–3 weeks. Rapid prenatal diagnosis in 48 hours can also be provided using quantitative fluorescent polymerase chain reaction or interphase fluorescence in situ hybridization.

Recently, a very reliable noninvasive prenatal screening strategy for common chromosomal aneuploidies using next-generation sequencing technology has come into clinical practice with very high sensitivity and specificity in early gestation.

**Ultrasound screening** Routine fetal anomaly scan is done at 18–20 weeks to look at the major malformations. Significant sonographic findings are seen in nearly all fetuses with trisomy 13, 77–100% of trisomy 18 and 33–50% of fetus with Down syndrome. Presence of multiple abnormalities raises the risk of chromosomal abnormality to 35%.

### Prenatal Diagnosis and Preimplantation Genetic Diagnosis

This is possible for single-gene disorders and any structural chromosomal rearrangement in one of the partners. Most common indications are known single-gene disorder or chromosomal abnormality in a previous affected child in the family. These tests can also be offered if the married couple is found to be carrier for any prevalent single-gene disorder on routine screening and mutations have been identified in the couple. Prenatal diagnosis for above mentioned disorders are widely available in India, however, experience with PGD for single-gene disorders is still limited in India.

### Newborn Screening (Also see Chapter 3.19)

Newborn screening (NBS) screens all newborns for disorders in which symptoms are not clinically evident and an early treatment can prevent or at least ameliorate the consequences. It is a comprehensive system of secondary prevention. Like any other screening program, it requires education, screening, diagnosis, management, follow-up and evaluation. It needs financial and personnel resources for sustainability and often challenged by economic, political and cultural considerations. The criteria for NBS program is given in **Box 2**. The list of disorders commonly included in a newborn screening program is given in **Table 3**.

**BOX 2** Criteria for newborn screening

- Should be an important health problem
- Facilities for diagnosis and treatment should be available
- Simple method of sample collection
- High benefit to cost ratio
- High sensitivity (no false negative) and high specificity (few false positive)
- The natural history should be adequately understood
- Appropriate follow-up of abnormal results so that affected children can be diagnosed and treated in a timely fashion.

**Table 3** List of disorders included in a newborn screening program

Phenylketonuria	Biotinidase deficiency
Hypothyroidism	Toxoplasmosis
Galactosemia	Hemoglobinopathies
Maple syrup urine disease	Deafness
Homocystinuria	Cyanotic congenital heart disease
Cystic fibrosis	Congenital adrenal hyperplasia
Tyrosinemia	Glucose-6-phosphate dehydrogenase deficiency

**Current Situation of Newborn Screening in India**

There have been several individual programs across India, e.g., program in Chandigarh, Goa, Gujarat, Kerala, UP, now very recently a program is launched in Haryana. Indian Council of Medical Research recently funded a multicenter feasibility study including five regions of the country screening 100,000 babies for congenital hypothyroidism (CH) and congenital adrenal hyperplasia. A high incidence of CH was detected (unpublished) and it was concluded that implementation in the country will be feasible in a phased manner. So far, there is no national NBS program.

**Presymptomatic Screening**

It includes screening of presymptomatic individuals at risk for adult-onset genetic disease where effective surveillance for the disease is the mainstay for at risk persons and the family. The benefits of this testing are targeted surveillance, prognosis assessment, and solving uncertainties. It has many debatable ethical and legal issues. Examples are familial hypercholesterolemia, factor V Leiden mutation, hereditary hemochromatosis, adult onset polycystic kidney disease, breast cancer, colon cancer, etc.

**TERTIARY PREVENTION**

Tertiary prevention includes providing supportive and rehabilitative care of individuals with various complications of genetic disorders to minimize the disability and dependency of these individuals and their family. The various strategies could be anticipatory guidance for prevention of complication such as obesity in achondroplasia, prophylactic posterior cervical fusion for Morquio syndrome, prophylactic mastectomy for individuals with high risk of breast cancers, proactive monitoring to avert development of complications, and providing rehabilitative and occupational services to maximize the potential of these differently able individuals such as providing orthosis for disorders with joint involvement, physiotherapy in neuromuscular disorders, hearing aids or speech therapy. Another most important but often neglected component is psychological support of these individuals and their families with genetic disorders. Year 2013

has been a landmark year as a very ambitious national program on *child health screening and early intervention services* [Rashtriya Bal Suraksha Karyakram (RBSK)] for universal screening, early detection and management has been launched by Government of India under the National Rural Health Mission of the Ministry of Health and Family Welfare. It targets approximately 27 crore children in the age group of 0–18 years with an objective to improve the overall quality of life of children through early detection of 4Ds (birth defects, diseases, deficiencies, development delay including disabilities). This program basically provides both secondary and tertiary prevention for nine common structural birth defects [neural tube defect, Down syndrome, cleft lip and palate/cleft palate alone, talipes (club foot), developmental dysplasia of the hip, congenital cataract, congenital deafness, congenital heart diseases and retinopathy of prematurity]. It also includes few important functional defects such as developmental delay, CH, sickle cell anemia, and  $\beta$ -thalassemia.

**Ethical Dilemmas in Genetic Screening**

To protect the child's autonomy, in the absence of any medical relevance, routine carrier testing or screening for recessive conditions and late onset disorders during childhood is not recommended by the American Academy of Pediatrics and ACMG. Possible *negative consequences of genetic screening* include stigmatization, labeling, or discrimination in work place or in insurance. It also carries a potential risk of misunderstanding the difference between affected and carrier.

**Challenges in the Development of Population-based Prevention Programs for Genetic Disorders in India**

The main challenges are other health priorities, limited political will, lack of awareness, limited resources both financial and personnel and lack of integration of genetic services with the existing programs. Countries, like India, are still struggling to achieve an appropriate control of other priority conditions, such as infection and malnutrition, and not yet attained Millennium Development Goal 4. Inclusion of these preventive strategies was not under the purview of government until last year. With RBSK, we are yet to recognize the actual burden (both social and economical) of these disorders and generate a political will to make prevention programs for genetic disorders universal. Recognizing the magnitude of genetic disorders in the community, it is imperative that more preventive measures for genetic disorders are integrated with the above strategies not only to decrease the burden but also to seed the soil by building up the capacity for genetic services at grass root levels.

**IN A NUTSHELL**

1. Genetic disorders are quite prevalent in the vast population of India.
2. In the absence of absolute cure for most of the genetic disorders, there is a need to develop effective preventive programs at various levels.
3. Prevention of genetic disorders requires mass education (both at community level and amongst health professionals) about common genetic disorders, availability of various screening tests, prenatal diagnosis and appropriate genetic counseling.
4. Any genetic screening tests should follow the principles of screening and should be accompanied with detailed information, pretest and post-test counseling and should maintain the autonomy and privacy of the individual being tested.

## Section 3 METABOLIC DISORDERS

**Section Editors** Madhulika Kabra, Neerja Gupta

### Chapter 3.1

## Approach to Inborn Errors of Metabolism

Chitra Prasad, CA Rupar

Inborn errors of metabolism (IEM) are in essence the *new kid on the block*. With improved detection and management of infectious diseases, attention is now focused on these genetic IEM with newer advances in diagnosis and management. Over a hundred years ago, in 1908, Sir Archibald Garrod, father of metabolic medicine, gave the prestigious Croonian lectures on four IEMs in London, UK (alkaptonuria, albinism, cystinuria and the benign pentosuria, **Figs 1A to C**). At the time these diseases were considered a variation, as a genetic trait that was not of clinical significance. However, the identification of phenylketonuria (PKU; the prototype of IEM) by Dr Asbjørn Følling a few years later in two mentally retarded siblings brought a chemical discovery into realm of management for mental retardation. It has been 80 years since PKU was first discovered. Early diagnosis through newborn screening (NBS) and dietary management of PKU has revolutionized the field of medicine.

Inborn errors of metabolism are individually rare; however, collectively their number increases everyday. There are close to 1,000 known metabolic disorders. Many of these disorders present in neonates, infants and children; hence, for a pediatrician it is essential that these disorders be recognized and managed appropriately as some of them are amenable to early detection and treatment. IEM are also genetic disorders, thus making genetic counseling around recurrence risk imperative for individuals who have had one affected child.

### EPIDEMIOLOGY

There are more than 1,500 articles, reviews and case reports on IEM from India and other nearby developing countries in the last 10 years. This highlights that IEM are certainly not rare in Southeast Asia. Reasons for increased interest and recognition are better awareness and availability of newer modalities of diagnosis for IEM. Many of these patients were previously labeled as having sepsis or other illnesses. Diagnosing and managing IEM in India and other developing countries is a challenge since some of the biochemical tests are not routinely available. Therapies of IEM are lifelong for most of the disorders and can be very expensive. We believe that IEM represent a true example of potential of collaborative medicine whereby families, many specialists, allied professionals, politicians and health-care advocates can play an important role. The information exchange is taking place at a pace never previously imagined. With access to the Internet even in remote areas, parents and families may be aware of the conditions before physicians. However, local innovations for therapies and diagnosis will need to take place in developing countries so that cost of diagnosis and management is no longer prohibitive.

### PATHOGENESIS

Metabolism is the process of renewal and breakdown of the tissues of the body. Enzymes are the catalysts in conversion of one chemical to another. Mutations affecting enzyme activity can cause the build-up of the substrate with subsequent deficiencies of the product. Accumulation of substrate can be diagnostically important; for example, phenylalanine in PKU (**Table 1**). Accumulation of substrate is one of the ways in which many IEM present (**Flow chart 1**). Other pathogenetic mechanisms involve the deficiency of the product, e.g., vitamin B<sub>12</sub> deficiency in transcobalamin deficiency. There can also be an accumulation of a minor metabolite, such as galactitol in galactosemia, which can cause cataracts.

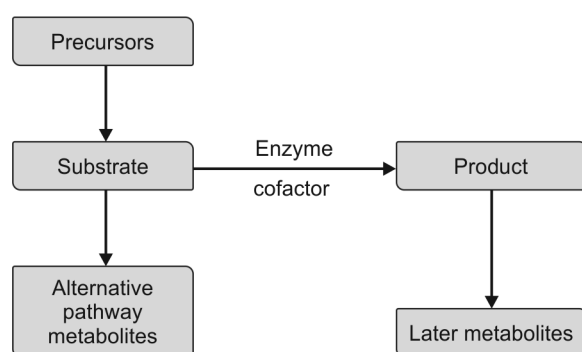

**Figures 1A to C** Alkaptonuria showing pigmentation on the (a) ears; and (b) in the eyes; (c) Albinism: a 6-year-old boy with light pigmentation of eyes and hair

**Table 1** Pathogenesis of inborn errors of metabolism (IEM)

Accumulated substrates proximal to the enzyme block
<ul style="list-style-type: none"> <li>• Storage disorder</li> <li>• Hyperammonemia in organic acidemia (indirect)</li> </ul>
Deficient products distal to the block
<ul style="list-style-type: none"> <li>• Biotinidase deficiency</li> <li>• Neurotransmitter deficiency (e.g. dopamine) in phenylketonuria</li> </ul>
Accumulation of unusual intermediates
<ul style="list-style-type: none"> <li>• Galactitol—galactosemia</li> <li>• Causing secondary carnitine deficiency in organic acidemia</li> </ul>
Other pathogenesis
<ul style="list-style-type: none"> <li>• Energy deprivation—mitochondrial disorders</li> <li>• Hypoglycemia and lactic acidosis in disorders of gluconeogenesis</li> <li>• Protein glycosylation abnormalities in congenital disorders of glycosylation</li> </ul>

**Flow chart 1** Pathogenesis of inborn errors of metabolism

Source: Dr Mark Korson, Associate Professor of Pediatrics at Tufts University School of Medicine.

Another disease-causing class of mutations can occur in genes that encode transporter proteins, e.g., the mitochondrial ornithine transporter, which transports ornithine across the inner mitochondrial membrane in the hyperammonemia, hyperornithinemia, homocitrullinemia syndrome. This results in intramitochondrial ornithine deficiency, which then leads to hyperammonemia. Bioppterin deficiency, which is a cofactor for phenylalanine hydroxylase, can cause features similar to infantile parkinsonism. Thus, IEM have many different underlying mechanisms. Some of the other examples of pathogenetic mechanisms are given in **Table 1**.

## INHERITANCE, GENETIC COUNSELING AND PRENATAL DIAGNOSIS

Most of the IEM are inherited in an autosomal recessive manner. With the increased incidence of consanguinity (inbreeding) that is commonly seen in various part of India and other countries, there is an increased incidence of autosomal recessive disorders. However, even within metabolic disorders, there are notable exceptions to autosomal recessive inheritance such as ornithine transcarbamylase (OTC) deficiency, Menkes disease, Hunter syndrome and Fabry disease (all X-linked), acute intermittent porphyria and hereditary hypercholesterolemia (autosomal dominant inheritance), and mitochondrial encephalomyopathy with lactic acidosis and stroke-like episodes (MELAS), myoclonic epilepsy and ragged red fibers (MERRF; maternal inheritance). A family history should always be obtained when there is a suspicion of IEM. Even within a very busy clinic, this information is too

important to be neglected. Once a formal diagnosis is made, a genetic counselor should ideally meet with the patient's family and explain the recurrence risk (e.g., in autosomal recessive disorders, there is a 1 in 4 risk for having an affected child and a 2/3 risk of being a carrier). These concepts should be explained with the use of diagrams and other genetic counseling aids. Where mutations are available, prenatal diagnosis can be done using molecular studies (preferable to enzymatic diagnosis since it can be difficult to differentiate carrier versus affected). Chorionic villus sampling or amniocentesis can be used. Since genetic counselors are not commonly available in India and developing countries, physicians should become familiar with basic genetic concepts.

The disease phenotype can vary remarkably within the family, a reminder that disease causing mutation may be influenced by gene-gene interaction and by gene-environment interaction.

## CLASSIFICATION

It is a daunting task to try and classify IEM. A number of classifications have been proposed for IEM. One is based on organelle involved: lysosomal disorders; peroxisomal disorders; mitochondrial disorders; and prelysosomal diseases. Another classification is based on size of the affected molecules:

- *Small molecule diseases* Diseases of amino acids, organic acidemia, and simple sugars (galactosemia, etc.), disorder of creatine metabolism (causing developmental delay, seizures and dystonia).
- *Complex molecule disease* Lysosomal disorders, mucopolysaccharidosis II (I-cell) disease, Gaucher disease, Hurler and Hunter syndrome.

## CLINICAL FEATURES

Inborn errors of metabolism are great mimickers of other disease processes, particularly sepsis. Almost all organ systems can be affected by IEM singly or in a multisystemic manner. Thus, it is helpful to keep IEM in the differential diagnosis of many medical conditions. The classic clinical scenario of IEM is of a healthy term infant who decompensates in the first few days after birth. During pregnancy, the fetus is protected, as the intermediate metabolic products cross placental barrier and are filtered through the mother's system.

## CLINICAL APPROACH TO INBORN ERRORS OF METABOLISM

Inborn errors of metabolism should be considered at all ages. Typical stresses, such as fasting, surgery, illness, constipation, excess protein, can worsen patients of IEM (intoxication type), such as amino acidopathies, maple syrup urine disease (MSUD), urea cycle disorders, organic acidemia and mitochondrial disorders. Of note, disorders of lysosomal metabolism (chronic neurodegenerative disorders), e.g., storage disorders, such as Batten disease, Hurler syndrome and Hunter syndrome, are not typically affected with acute stresses mentioned above. A few pointers in history of IEM are listed in **Box 1**. Some of the more common presentations and period of onset of IEM are discussed in **Box 1**.

### Pregnancy

A minor fraction of patients with hemolysis, elevated liver enzymes and low platelets (HELLP) syndrome cases are caused by fetal homozygous long-chain 3-hydroxyacyl-CoA dehydrogenase (LCHAD) deficiency. OTC deficiency can present with increased sleepiness and coma in female carriers.

**BOX 1** History pointers which may be useful for inborn error of metabolism

- Diminished exercise intolerance (e.g., mitochondrial disorders)
- Unusual severity of symptoms during illness (e.g., organic acidemia, mitochondrial disorders)
- Unusual odors (e.g., MSUD)
- Avoidance/intolerance of certain foods, e.g., urea cycle disorders (e.g., avoidance of protein)
- Family history of metabolic-oriented symptoms and consanguinity (e.g., autosomal recessive disorders)
- Sudden infant death syndrome [SIDS, medium-chain acyl-CoA dehydrogenase deficiency (e.g., MCAD)]
- Regression of milestones (e.g., metachromatic leukodystrophy)

**Fetus****Nonimmune Hydrops**

A number of lysosomal disorders can present as nonimmune hydrops. Disorders such as sialidosis, mucopolysaccharidosis VII (MPS VII), and congenital disorders of glycosylation (CDG) should be considered when nonimmune hydrops are identified. Prognosis is usually poor.

**Lack of/Poor Fetal Movements/Arthrogryposis/  
Polyhydramnios**

Glycogen storage type IV, CDG can present with poor fetal movements and arthrogryposis.

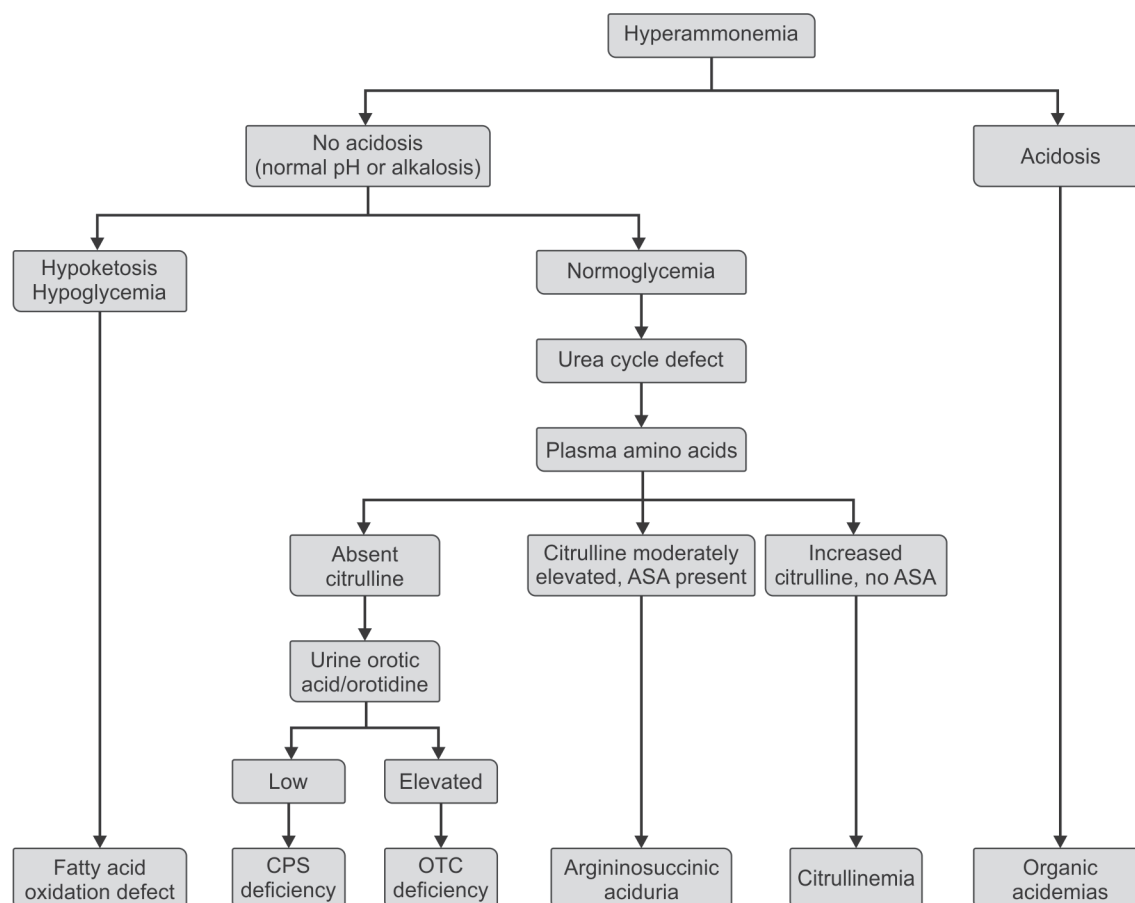

**Neonatal Period**

Neonates have a very limited repertoire by which they manifest disease symptoms. IEM symptoms during neonatal period are indistinguishable from sepsis, such as vomiting, cyanosis, lethargy, seizures, hypotonia, poor feeding, poor sucking and hiccups. Hence, IEM should always be considered in the differential diagnosis of sepsis. Some of the common IEM to consider in this age group are aminoacidopathies, urea cycle disorders, organic acidemia, Zellweger syndrome and seizure disorders such as pyridoxine dependency.

A child who is normal at birth can present in the newborn period with a catastrophic illness or encephalopathy. Such a child should be screened for biochemical disturbances including hyperammonemia, hypoglycemia, metabolic acidosis and lactic acidosis.

**Hyperammonemia**

Deficiency of any of the six enzymes in the urea cycle results in the accumulation of ammonia and leads to encephalopathy. Episodes of encephalopathy and associated symptoms are unpredictable and, if untreated, are lethal or produce devastating neurologic sequelae in long-term survivors. Urea cycle disorders are typically associated with respiratory alkalosis. Rising ammonia level is a medical emergency as there is a risk of raised intracranial pressure. High ammonia can also be caused by organic acidemia and fatty acid oxidation disorders. In this situation, there will be metabolic acidosis associated with hyperammonemia (**Flow chart 2**). Arginase deficiency (the last enzyme) typically presents with spastic diplegia rather than hyperammonemia in the newborn period.

**Flow chart 2** Approach to hyperammonemia

Abbreviations: ASA, argininosuccinic aciduria; OTC, ornithine transcarbamylase; CPS, carbamoyl phosphate synthetase.

Source: Modified from Burton B. Inborn errors of metabolism in infancy: a guide to diagnosis. *Pediatrics*.1998;102:e69-77 and Summar M. Current strategies for the management of neonatal urea cycle disorders. *J Pediatr*. 2001;138:S30-9.

*In any lethargic, septic-appearing neonate, child, adult without a diagnosis measure blood ammonia levels!!*

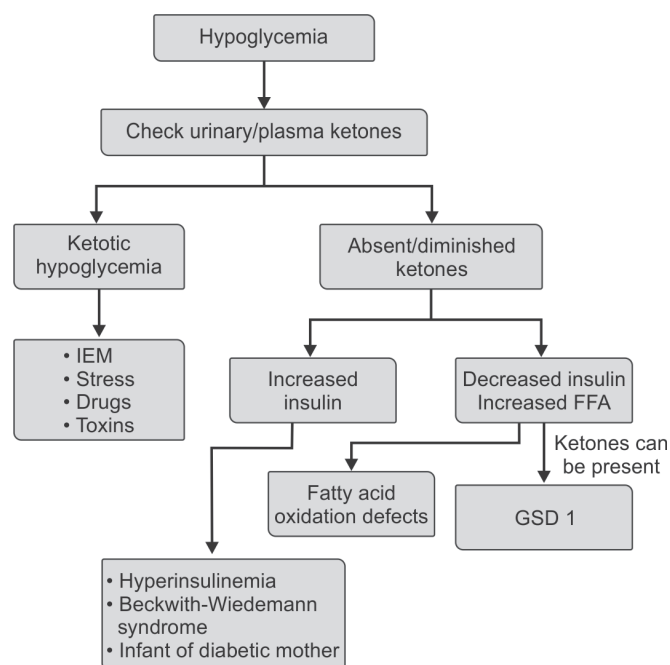

### Hypoglycemia

Although hypoglycemia can be a presenting feature of many unrelated conditions (sepsis, drugs, insulin, cardiac conditions, etc.), nevertheless, some hypoglycemic episodes could be due to IEM, particularly in cases of multisystemic involvement (**Flow chart 3**). Glycogen storage disease (GSD) type 0, I, III, VI and IX; glucose transporter 2 deficiency; fatty acid oxidation [medium-chain acyl-CoA dehydrogenase (MCAD)]; ketogenesis disorders; and gluconeogenesis disorders can cause hypoglycemia. Other ketogenesis disorders [3-hydroxy-3-methyl-glutaryl-CoA (HMG-CoA) lyase deficiency], and gluconeogenesis disorders (fructose-1,6-biphosphatase deficiency) can also cause hypoglycemia in neonate and infancy.

### Metabolic Acidosis

Metabolic acidosis is characterized by decreases in arterial blood pH (pH < 7.30), plasma bicarbonate and pCO<sub>2</sub>. This is classically caused by organic acidemia. A number of these disorders are due to defects in the catabolic pathways for the branched chain amino acids, or other amino acids after deamination. Examples of organic acidemia include methylmalonic acidemia, propionic acidemia (PA), and isovaleric acidemia (IVA). These disorders may present in the neonatal period with an increased anion gap (>15) metabolic acidosis (**Flow chart 4**). The most severe presentation is of a healthy newborn infant who becomes very ill within the first 24–48 hours with profound metabolic acidosis, hyperammonemia (which is due to secondary impairment of the urea cycle), urine ketosis and encephalopathy. Features of cerebral edema with a bulging fontanel may be present. Presence of ketones in the urine may be a clue for organic acidemia as urinary ketones are normally not seen in a neonate.

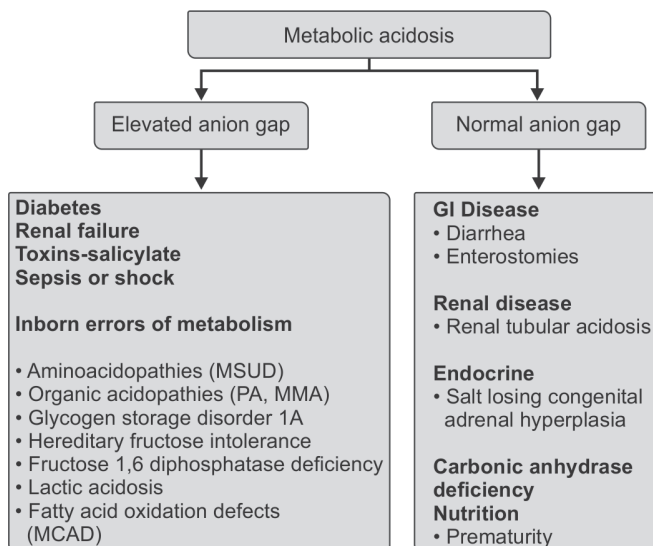

**Flow chart 3** Approach to hypoglycemia

**Abbreviations:** IEM, inborn errors of metabolism; FFA, free fatty acids; GSD, glycogen storage disease.

**Source:** Mark Korson, Associate Professor of Pediatrics at Tufts University School of Medicine.

**Flow chart 4** Approach to metabolic acidosis

**Abbreviations:** MSUD, maple syrup urine disease; MCAD, medium-chain acyl-CoA dehydrogenase; GI, gastrointestinal; PA, propionic acidemia; MMA, methylmalonic acidemia.

**Source:** Dr Mark Korson, Associate Professor of Pediatrics at Tufts University School of Medicine; and modified from Prasad C, Rupar CA. Inborn errors of metabolism in infancy and childhood presenting with metabolic acidosis. Indian Journal of Practical Pediatrics. 2010;12:155.

### Lactic Acidosis

Lactic acidosis is the most common metabolic acidosis. It can be caused by shock or poor perfusion from a variety of causes including congenital heart defects (e.g., coarctation of the aorta and hypoplastic left heart syndrome). Lactate levels less than 10 mmol/L may not result in an elevated anion gap; however, high anion gap metabolic acidosis can be due to lactic acidosis (levels > 10–15 mmol/L). There are primary lactic acidosis disorders such as pyruvate dehydrogenase (PDH) deficiency, pyruvate carboxylase deficiency and respiratory chain disorders. Elevations in lactate reflect increased concentrations of pyruvate, the assay of which is not easily available in most laboratories. Accumulated pyruvate is also converted to lactate and alanine. The ratio of plasma lactate concentration to pyruvate reflects the redox potential within the cytosol. A decreased lactate/pyruvate ratio of less than 10 indicates PDH deficiency and an increased lactate/pyruvate ratio (>25) is suggestive of pyruvate carboxylase deficiency or mitochondrial respiratory chain abnormalities. Secondary lactic acidosis is also a feature of organic acidemia and fatty acid  $\beta$ -oxidation disorders.

### Clinical Clues in Neonates/Children

#### Unusual Smells

A specific smell may be an indication of IEM. However, on other occasions this may not be reliable. Common examples include smell of maple syrup (MSUD), sweaty feet odor (IVA, type II glutaric aciduria), fishy odor (trimethylaminuria, carnitine therapy) and cat urine odor (3-methylcrotonylcarboxylase deficiency).

#### Liver Disease

Cholestatic jaundice should also be investigated for IEM. Niemann-Pick C,  $\alpha$ -1 antitrypsin deficiency, galactosemia, hereditary fructose intolerance, tyrosinemia. GSD IV can present with predominant hepatomegaly. Wilson disease presents with liver disease in early childhood and later causes neurological involvement.

### Hepatosplenomegaly

There should be suspicion of a storage disorder with hepatosplenomegaly. Differential diagnoses include hematological and autoimmune disorders, Gaucher disease, Niemann-Pick A, Niemann-Pick B, mucopolysaccharidoses. In many instances there will be other systemic features as well.

### Neurologic Disease

Neurological system is affected in many IEM. The IEM also affect different parts of nervous system causing different symptomatology. Neurological symptoms and respective disorders of metabolism are listed in **Box 2**.

### Psychiatric Symptoms

Unusual behaviors and psychiatric manifestations are now recognized for some of the IEM. Urea cycle disorders, for example, OTC deficiency can present with bizarre behaviors and may be wrongly diagnosed as a psychiatric disorder. Porphyrrias (hepatic) have psychiatric manifestations. A baseline metabolic workup should be done when there are atypical features or a family history of IEM.

### Cardiomyopathy

**Pompe disease** (glycogen storage disorder Type II): It can cause cardiomyopathy. A history of sweating during feeding should prompt cardiac investigations. Carnitine transporter deficiency presents with cardiomyopathy. Prognosis is good if carnitine is supplemented early and given for life. Fabry disease may also present with hypertrophic cardiomyopathy.

### Storage Disease

Coarse facies, hepatosplenomegaly, skeletal dysplasia, vision and hearing involvement, neurodegenerative course are typical for mucopolysaccharidoses, mucopolipidosis II (**Fig. 3**) and oligosaccharidoses.

### Skin

A thorough clinic examination at initial assessment may reduce the chances of missing a diagnosis. For example, one of our patients labeled as having a psychiatric disorder was later found to have classic angiokeratoma and was diagnosed with Fabry disease.

### BOX 2 Neurological signs and symptoms of inborn errors of metabolism

- Hypotonia
  - Disorder of peroxisomal biogenesis (prototype is Zellweger syndrome)
  - Pompe disease
  - Congenital disorders of glycosylation
- Seizures
  - Nonketotic hyperglycinemia
  - Pyridoxine and pyridoxal phosphate deficiency
  - Isolated sulfite oxidase and molybdenum cofactor deficiency
- Delayed development
  - Many disorders, i.e., untreated PKU
- Ataxia
  - Congenital disorders of glycosylation syndrome (**Fig. 2**)
  - Abetalipoproteinemia
- Loss of consciousness/unexplained lethargy
  - Hyperammonemia
- Dystonia and other movement disorders
  - Glutaric acidemia type 1
  - Leigh's disease
  - Pterin cofactor deficiency
- Childhood dementia
  - Metachromatic leukodystrophy
- Spastic paraplegia/cerebral palsy-like picture
  - Arginase deficiency
- Strokes
  - MELAS
  - Homocystinuria
  - Fabry disease
- Muscle disease (myopathy/rhabdomyolysis)
  - Pompe disease
  - Carnitine palmitoyl transferase II
  - McArdle disease (glycogen storage type V)

### Renal Disease

Fabry disease can cause glomerular involvement and renal failure. Tubular function can be involved in mitochondrial disorders and galactosemia. Cystinosis can also impair kidney function.

### Dysmorphism/Multiple Congenital Malformations

Many disorders initially thought to be pure genetic syndromes have now been identified as having a metabolic basis.

**Figure 2** A 9-month-old male infant with inverted nipples and fat pads (Congenital disorders of glycosylation)

**Figure 3** Child with mucopolipidosis type II with coarse features and large tongue

For example, peroxisomal disorders generally are associated with dysmorphic features characterized by the Zellweger spectrum disorders (high forehead, flat occiput, large anterior fontanel, hypoplastic supraorbital ridges, epicanthal folds, broad nasal bridge, anteverted nostrils and micrognathia). Many of the CDG exhibit dysmorphic features (large ears, strabismus, and abnormal fat distribution, **Fig. 2**). Smith-Lemli-Opitz syndrome disorder of cholesterol metabolism causes ptosis, facial dysmorphism and the characteristic 2/3 toe syndactyly (**Figs 4A and B**). Mevalonic aciduria can also cause dysmorphic features with frontal bossing and failure to thrive.

**Figures 4A and B** Smith-Lemli-Opitz syndrome. (A) A young girl with hypotonia; (B) Syndactyly of 2/3 toe

Source: Reproduced with permission from Wiley Publications (Prasad C, Marles S, Prasad AN, et al. Smith-Lemli-Opitz syndrome: new mutation with a mild phenotype. *Am J Med Genet.* 2002;108:64-8).

### Skeletal/Skeletal Dysplasia

Morquio syndrome (type IV) has a predominant skeletal phenotype. Rhizomelic chondrodysplasia punctata (RCDP) is associated with short stature, rhizomelic shortening and stippling calcification. This is a peroxisomal disorder of plasmalogen biosynthesis. Homocystinuria causes marfanoid habitus with skeletal involvement (**Figs 5A to F**).

### Lung Disease

Interstitial lung opacities are seen in Niemann-Pick B and Gaucher disease. Pompe disease and other neuromuscular diseases can also affect lung function.

### Eye Involvement

Eye examination can provide clues to many IEM. Cataracts are seen in galactosemia and RCDP. Retinitis pigmentosa is a clue to mitochondrial disorders or abetalipoproteinemia. Corneal clouding may suggest Hurler syndrome. Macular cherry red spot (**Fig. 6**) is a characteristic feature of GM1 gangliosidosis and Tay-Sachs disease. Lens dislocation is a clue to homocystinuria (**Fig. 5**; also skeletal marfanoid phenotype) or molybdenum cofactor deficiency/isolated sulfite oxidase deficiency.

### Hearing

Recurrent ear infections are typically seen in MPS and hearing loss is also seen in biotinidase deficiency.

### Hair

*Menkes kinky hair disease* Pili torti hair abnormality is seen (X-linked recessive, **Figs 7A and B**). Alopecia is seen in untreated biotinidase deficiency.

**Figures 5A to F** Physical signs of homocystinuria. (A) Lens dislocation; (B) Marfanoid habitus; (C) Pectus excavatum; (D) Long fingers; (E) Pes cavus; (F) High arched palate

**Figure 6** Cherry red spot in the retina

### Endocrine Dysfunction

Congenital hypothyroidism and persistent hyperinsulinemic hypoglycemia in CDG; adrenal dysfunction and disorders of sexual development in congenital adrenal hyperplasia; and primary adrenal insufficiency in adrenoleukodystrophy.

### Hematological

Transcobalamin deficiency and gastric intrinsic factor deficiency can mimic leukemia. Thrombocytopenia and leukopenia is a clue to organic acidemia.

## INVESTIGATIONS

Investigations for IEM are summarized in **Tables 2 and 3**. We have also briefly summarized the investigations that need to be carried out at the time of death to ensure that appropriate samples are obtained which may be helpful in making a diagnosis (**Box 3**).

### BOX 3 Considerations regarding metabolic autopsy

- Notify pathology early
- Plasma, urine, bile, vitreous humor samples (can be used for acylcarnitine profile, DNA banking)
- Skin biopsy from well-perfused area (can isolate DNA)
- Permission for autopsy/multiple biopsies
- Flash-freeze liver
- Photograph and skeletal survey

## THERAPIES FOR INBORN ERRORS OF METABOLISM

It is said that *one man's meat is another man's poison*. This is exemplified by many urea cycle patients who intuitively avoid protein as it causes them to be sick.

Therapy for IEM has to be individualized. A trained metabolic dietitian is an essential part of the team to help with the dietary modifications of the particular IEM. Once the diet is modified, there can be secondary effects on other systems such as the bone health, deficiencies of trace elements and minerals. Hence, regular monitoring and expertise of dietitian is essential for ensuring proper growth and development despite the modified diet. Important treatment modalities are listed below:

- **Dietary adjustment**
  - Substrate restriction, e.g., low phenylalanine formula in PKU (most well-studied)
  - Branched chain amino acids in MSUD
  - Galactose in galactosemia (difficult disorder to treat despite galactose restriction due to endogenous production)
- **Replacement of deficient product**
  - Thyroxine in congenital hypothyroidism
  - Biotin in biotinidase deficiency (very good prognosis if treated after NBS)
- **Vitamin supplementation—cofactors** (activation of dysfunctional protein)
  - Pyridoxine (vitamin B<sub>6</sub>) in homocystinuria
  - Thiamine in MSUD
- **Alternative pathway**
  - Carnitine to facilitate metabolic excretion of intermediate compounds in organic acidemias
  - Sodium benzoate and phenylacetate—urea cycle disorders
- **Enzyme replacement**

For example, in Gaucher disease (glucocerebrosidase). This has made a dramatic improvement in the clinical course of Gaucher disease. The enzyme therapy is given intravenously every two weeks. Other disorders for which enzyme replacement (ERT) is available are MPS I, II, IV, VI, Fabry disease. There are newer ERTs in the pipeline. So far none of the other ERTs have had as dramatic response as in Gaucher disease.
- **Protein replacement** Factor VIII replacement in hemophilia.
- **Hemodialysis/peritoneal dialysis** Removal of ammonia in urea cycle disorders. This is more effective than peritoneal dialysis.
- **Organ transplantation** Liver transplantation in OTC deficiency and other urea cycle disorders, organic acidemia [methylmalonic acidemia (MMA) and PA]. Combined liver and kidney transplant may have to be considered for MMA.

**Figures 7A and B** A young boy with Menkes kinky hair disease. (A) Gross appearance of hair; (B) Microscopic appearance showing Pili torti

**Table 2** Recommended laboratory investigations (examples of metabolic disorders are listed in parentheses)

Preliminary tests	Specialized tests

**Table 3** Other investigations that are performed in inborn errors of metabolism

Abdominal ultrasound	Rule out hepatosplenomegaly (storage disorders) Renal cysts (glutaric aciduria II)
Cardiac echo/MRI	Cardiomyopathy (Pompe disease), Pericardial effusion (CDG syndrome)
Cranial MRI/MRS	White matter changes in leukodystrophy Creatine peak absent in MRS in disorders of creatine metabolism Inverted lactate peak in mitochondrial disorders
Bone density	Low in many diet-related disorders
Neuropsychological testing	Many IEM (such as PKU monitoring)
Vision testing	Disorders with ophthalmological manifestations (homocystinuria)
Audiology	Disorders with hearing involvement (biotinidase deficiency)
EEG	Characteristic abnormalities in some IEM (triphasic waves in hyperammonemic encephalopathy)

Abbreviations: IEM, inborn errors of metabolism; EEG, electroencephalography; PKU, phenylketonuria; CDG, congenital disorders of glycosylation; MRS, magnetic resonance spectroscopy; MRI, magnetic resonance imaging.

- *Bone marrow transplantation, cord cell transplant* Lysosomal storage disorder—Krabbe disease
- *Gene therapy* Adenosine deaminase deficiency
- Substrate reduction, chaperone therapies (e.g., Miglustat for Niemann-Pick C disease)
- *Newer drugs*
  - Carbaglu (N-acetylglutamate synthase) for N-acetylglutamate synthase (NAGS) deficiency and carbamoyl phosphate synthetase (CPS) deficiency. It has also been used for acute hyperammonemia for MMA and PA
  - Kuvan (biopterin) cofactor for phenylalanine hydroxylase deficiency for PKU
  - Normosang (heme) infusion for acute intermittent porphyria

## PREVENTION

Early detection can make considerable difference in the prognosis of IEM. It has been almost 54 years since NBS was first instituted. In the last decade, due to the advent of tandem mass spectrometry, expanded NBS has become a mandatory public health strategy in most developed and some developing countries. The technology allows the inexpensive simultaneous detection of more than 30 different metabolic disorders in one single blood spot specimen with great accuracy and precision. The sensitivity and specificity of this method can be up to 99% and 99.995%, respectively for most amino acid disorders, organic acidemia, and fatty acid oxidation defects. Cost-effectiveness studies have confirmed that the savings achieved through the use of expanded NBS programs are significantly greater than the costs of implementation. NBS is discussed in detail in Chapter 3.19.

### IN A NUTSHELL

1. Genetically determined variability in biochemical processes may result in inborn errors of metabolism (IEM).
2. To understand the multisystem aspects and diagnostic strategies for the metabolic disorders.
3. To recognize the signs and symptoms suggestive of an IEM and formulate a logical diagnostic approach to determining when an IEM is suspected.
4. To describe the characteristics of different classes of metabolic syndromes.
5. To become familiar with the neonatal screening (criteria, advantages, pitfalls) for metabolic disorders.
6. To learn the principles of managing and treating some of the metabolic disorders, e.g., PKU and be aware of some of the newer therapies.
7. To recognize the importance of metabolic investigations in event of stillbirth, early neonatal death or in a case of sudden unexplained infant death (sudden infant death syndrome).
8. IEM have a genetic basis in most instances, so establishing a diagnosis will also help in genetic counseling, prenatal diagnosis and family carrier screening.

## Chapter 3.2

# Defects of Amino Acid Metabolism

Anil B Jalan, Ketki V Kudalkar

Aminoacidopathies is a group of rare and diverse inborn errors of metabolism which results in the accumulation of some amino acids or deficiency of one or more amino acids in the blood and/or urine, affecting about 1 in 1,000 humans worldwide. The majority of these disorders present in the neonatal period and most of them are inherited in autosomal recessive manner, having metabolic disturbances and neurologic manifestations. The range and severity of symptoms is hugely variable, ranging from asymptomatic to life-threatening metabolic decompensation at neonatal age, encompassing slow deterioration of mental capacities at later age. Even though some present at birth, presentation may be later in life. These disorders can be subdivided into organic acidurias, urea cycle defects, transport defects of urea cycle intermediates, and remaining aminoacidopathies.

Deficiencies of enzymes involved in amino acid metabolism frequently result in accumulation of toxic substances and subsequent organ damage. The organs most frequently affected are brain, liver and kidneys. Accumulation of a metabolite may lead to symptoms of toxicity, e.g., ammonia or deficiency of an essential metabolite, e.g., glucose may produce symptoms. This in turn depends on the type and severity of enzyme deficiency. It also depends partially on protein or amino acid intake or catabolism. Acute symptoms are often associated with catabolic states that lead to breakdown of endogenous proteins and release of large amounts of amino acids, whereas some disorders cause chronic neurological damage without acute decompensation.

Typical presenting features for aminoacidopathies are listed in **Box 1**.

### BOX 1 Typical presenting features of aminoacidopathies

- Acute coma/ataxia/encephalopathy
- Progressive neurological symptoms
- Multisystem disorder
- Unexplained acidosis
- Ketonuria
- Hyperammonemia
- Failure to thrive
- Vomiting/diarrhea.

## EVALUATION OF AMINOACIDOPATHIES

Amino acid profiling is routinely performed in plasma or serum, urine and sometimes even in cerebrospinal fluid (CSF). For majority of clinical situations, fasting plasma is preferred; however in severe metabolic disorders, random samples are also adequate. Routinely 22 or 24 amino acids are analyzed but a good amino acid analyzer can produce an aminoacidogram up to 30 or even more amino acids. A clinician should choose a method from the below, depending on the clinical situation and urgency. Cost may be an issue especially in developing countries.

For routine clinical purposes one of the following methods are used:

- a. **HPLC (High Performance Liquid Chromatography)** Quantitative analysis on plasma/serum, urine or CSF. Precolumn derivatization or postcolumn derivatization techniques are available. This is generally a lengthy procedure. Analysis time

can vary from 120–180 min. Depending on various instruments and methods.

- b. **UPLC/UHPLC (Ultra Performance Liquid Chromatography/ Ultra High Performance Liquid Chromatography)** This is a relatively more sophisticated form of HPLC with changes in hardware and software. The main advantage is faster techniques. Typical amino acid runs can be completed in 18–30 min instead of 120–180 min, quantitative method, and good for all the samples—plasma/serum, urine or CSF.
- c. **Ion Exchange Chromatography (Biochrome Analyzer)** This method is supposed to be gold standard for amino acid analysis, is quantitative with excellent results. 24–30 amino acids can be analyzed in any tissue—Plasma/Serum, urine or CSF. Run times are usually 120–180 min.
- d. **LC-MS/MS Tests** for 22–24 important amino acids can be performed both on plasma or urine. It provides quantitative analysis and is very fast. With a standard kit (EZphast), the total procedure time is usually 17 minutes.
- e. **Tandem Mass Spectrometry** It can analyze 10–12 important amino acids from dried blood spots, as a part of routine newborn screening. These results are rather semi-quantitative; however, run times are 60–120s. This is a good method for newborn screening, however, abnormal results need to be confirmed with quantitative analysis with any of the above procedures.

## Samples

Fasting EDTA or heparinized plasma is the preferred sample. After collection, sample should be immediately centrifuged and plasma should be stored frozen till analysis at  $-20^{\circ}\text{C}$ . Serum also is adequate for routine clinical analysis. In our experience urine amino acid does not provide much information as a primary test. However, in certain clinical situations, urine amino acids are very valuable, for example, lysinuric protein intolerance or where a clinician is interested in markers of bone loss or muscle wasting (e.g., hydroxyproline, hydroxylysine and cystine). A clinician must remember that a hemolysed sample will have lot of alterations in amino acids. The sample may show falsely high taurine, aspartic acid, ornithine, phosphoethanolamine and glycine (in our experience) and decreased arginine and cystine.

## Interpretation

Identification of aminoacidopathies by amino acid analysis is sometimes a difficult task. Identification of not only elevated but reduced amino acid levels also must be actively searched for. A practical guide is given below in **Table 1**. If results of amino acid analysis are nonconclusive, a repeat analysis in a different state of feeding (either fasting or post feed, especially protein load) may reveal subtle abnormalities. A typical pattern of abnormalities is more important than an isolated abnormality. For example, elevated leucine along with valine and isoleucine may suggest MSUD but alone it may suggest probably catabolic state.

Amino acid analysis in CSF also should be considered in all neonates and children presenting with seizures and unexplained neurological disorders. Interpretation will depend on the pattern of amino acid abnormalities (**Fig. 1**).

At present, dietary management is the mainstay of treatment for most aminoacidopathies. Dietary treatment aims to prevent accumulation of the substrates and associated metabolites to toxic levels, and to restore deficiencies of the enzymatic products. This can be accomplished by avoiding offending amino acids and substituting essential amino acids. Many a times simple low protein diet is helpful, e.g., glycine encephalopathy (NKHG).

## MAPLE SYRUP URINE DISEASE

In 1954, a family of four children was described where all affected newborns were described to have maple syrup urine disease (MSUD). Progressive disorder affected nervous system was fatal in each of them in the first weeks of life. MSUD is inherited in autosomal recessive manner and is caused by a deficiency in ability to metabolize the branched-chain amino acids, leucine, isoleucine and valine.

The branched chain  $\alpha$ -keto-acid dehydrogenase (BCKDH) complex is a multienzyme complex similar to pyruvate dehydrogenase complex. It carries out the decarboxylation of these branched chain amino acids. The enzyme complex consists of four subunits, including  $E_1\alpha$ ,  $E_1\beta$ ,  $E_2$  and  $E_3$ . MSUD results from mutations in any one of the *BCKDHA* ( $E_1\alpha$ ), *BCKDHB* ( $E_1\beta$ ), *DBT* ( $E_2$ ), and *DLD* ( $E_3$ ) genes. MSUD is estimated to occur in 1:100,000 newborns (Fig. 2).

### Clinical Symptoms

Maple syrup urine disease usually presents early in infancy with poor feeding, vomiting, lethargy and developmental delay.

If untreated, MSUD may lead to seizures, coma or even death. The most common form of MSUD (severe form) presents with progressive encephalopathy in the first days of life. Babies even though normal at birth soon begin to have feeding difficulties, at times with vomiting, slowly progressing to lethargy and coma within few days after protein feeds. Though metabolic acidosis is not very common, it is evident with increased anion gap and elevated branched chain amino acids in blood and urine. Hypoglycemia may occur and neurologic deterioration may be rapid. Cerebral edema results in encephalopathy. Alternating hyper- and hypotonia and often scissoring of legs or opisthotonos and boggy fontanel are also seen. Other less acute presentations (mild form) are associated with psychomotor retardation, fluctuating/progressive neurologic disease, and recurrent ketoacidotic decompensation. Neurological symptoms are evident in all forms of MSUD by 2 years at least.

### Diagnosis

The diagnosis of MSUD is based on measurement of plasma branched chain amino acids, *leucine*, *isoleucine* and *valine* along

**Table 1** Amino acid disorders and their diagnosis

Amino acids	Possible causes	Additional tests
1. Alanine (Increase)	Mitochondrial disorders Lactate/Pyruvate metabolism disorders Hyperammonemia syndrome	Ammonia, lactate, pyruvate Full plasma amino acids (If alanine elevation is detected on NBS) Urine orotic acid

23. Tyrosine (Increase)	Tyrosinemia type I (HT1) Tyrosinemia type II Tyrosinemia type III Transient tyrosinemia of the newborn, liver disease, Prematurity Hyperalimentation	Plasma amino acids Urine organic acids Urine succinyl acetone
24. Tyrosine (Decrease)	PKU and pterin disorders	Pterin studies in urine and DBS DHPR enzyme assay

with alloisoleucine and documenting elevated levels. In MSUD accumulation of these amino acids in very high levels occurs as they are not decarboxylated, the highest being leucine. Val/Phe, (Leu+Ile)/Phe and (Leu+Ile)/Ala ratios have also been informative in MSUD. The oxidative decarboxylation block in MSUD also results in accumulation of branched-chain keto acids, 2-oxoisocaproic acid from leucine, 2-oxo-3-methylvaleric acid from isoleucine and 2-oxoisovaleric acid from valine, which are detected in

high levels in urine of affected patients by gas chromatography-mass spectrometry (GC-MS). The deficiency of BCKDH enzyme complex activity can be measured in cultured fibroblasts. Antenatal diagnosis is possible by measurement of enzyme activity in chorionic villi cells or cultured amniocytes. However, molecular analysis of mutations in the *BCKDHA*, *BCKDHB*, *DBT* and *DLD* genes can provide a better method for prenatal diagnosis in families in which the mutation(s) is/are known (**Fig. 3**).

**Figure 1** Interpretation of amino acids in CSF

### Treatment

Aggressive intervention during acute crisis helps in reducing branched chain amino acid (BCAA) levels, especially hemodialysis is the fastest way of reducing BCAA levels in plasma. IV glucose and insulin may provide alternate energy that reduces protein catabolism and enhances anabolism. Long-term diet therapy involves restriction of protein intake and special formulas that are devoid of branched chain amino acids. In some patients, thiamine (10 mg/kg/day) trial may be considered depending upon response to therapy. Close monitoring of patients is essential to achieve optimal ranges of BCAA (Leu—100–250  $\mu\text{mol/L}$ , Ile—50–150  $\mu\text{mol/L}$  and Val—150–250  $\mu\text{mol/L}$ ). The prognosis depends on prompt and strict adherence to therapy.

### PHENYLKETONURIA (PKU)

The enzyme phenylalanine hydroxylase converts essential amino acid phenylalanine to tyrosine. Deficiency of phenylalanine hydroxylase causes PKU with severe central nervous system symptoms. PKU was the first neurogenetic disorder identified in 1934 by Fölling, the first successfully treated inborn error of metabolism (Bickel, 1953) and the disorder instrumental for the introduction of neonatal screening. It was Dr. Robert Guthrie who first developed a test for phenylalanine in dried blood spots for new born screening of phenylketonuria (PKU) and era of newborn screening began about 50 years back. Phenylalanine metabolism takes place in the cytosol. Enzyme phenylalanine hydroxylase converts phenylalanine to tyrosine. It requires tetrahydrobiopterin (BH4) as a cofactor. The deficiency of phenylalanine hydroxylase or tetrahydrobiopterin results in accumulation of phenylalanine which is transaminated to phenylpyruvate (**Fig. 4**).

### Clinical Symptoms

Affected children appear normal at birth or even in early neonatal period. Later they exhibit irritability, posturing, increased deep tendon reflexes, microcephaly, seizures and vomiting. If untreated the child may develop severe brain damage with intellectual disability, seizures and spasticity. Pigmentation of skin and hair may also be seen.

Phenylalanine is the major toxic metabolite in PKU. It accumulates in the blood and prevents transport of other long neutral amino acids (LNAA) across the blood brain barrier inhibiting the synthesis of neurotransmitters in the brain. This results in severe intellectual disability and white matter disease.

Untreated maternal PKU may result in high levels of phenylalanine in mothers which in turn crosses placenta and affects developing brain. Newborn may have neurological damage. To avoid such toxic and teratogenic effect of phenylalanine, mothers must receive proper dietary therapy and control of phenylalanine intake during pregnancy.

### Diagnosis

Screening for PKU began with Guthrie's bacterial assay. Now greater sensitivity has been achieved by implementation of TMS. An increased level of phenylalanine and increased phenylalanine/tyrosine ratio is suggestive of PKU. In classical PKU levels of phenylalanine are typically greater than 600  $\mu\text{mol/L}$ . Mild or tetrahydrobiopterin (BH4) responsive PKU show levels less than 600  $\mu\text{mol/L}$  typically and the levels improve after BH4 supplementation. All newborns with PKU should be screened for BH4 defects. Mutation analysis of PAH gene may allow prediction of severity and BH4 sensitivity.

### Treatment

Children with PKU need to maintain phenylalanine levels controlled throughout their life. Special dietary PKU formulas and various phenylalanine restricted foods are available for PKU patients by various companies. Supplementation of essential amino acids and trace elements is necessary. BH4 supplementation should be tried in BH4 deficient patients. Monitoring of phenylalanine and tyrosine levels on a regular basis to follow dietary control is absolutely essential.

### TYROSINEMIA TYPE 1

Tyrosinemia type I was described in 1957. It is an inborn error of tyrosine metabolism caused by the deficiency of fumarylacetoacetate hydrolase (FAH). It is estimated to occur in less than 1:100,000 livebirths worldwide but is more common in French

**Figure 2** Branched chain amino acids metabolism

**Figure 3** Maple syrup urine disease—metabolites

**Figure 4** Phenylalanine metabolism

Canadians (1 in 12,500). Deficiency of FAH causes accumulation of fumarylacetoacetate, succinyl acetoacetate and succinylacetone. These are highly toxic substances and cause inhibition of several enzymes including 4-hydroxyl phenyl pyruvate dioxygenase and aminolevulinate dehydratase and are carcinogenic (**Fig. 5**).

### Clinical Symptoms

Tyrosinemia type I acute or neonatal type may present in the first few months of life with severe failure to thrive, vomiting, hepatomegaly, liver dysfunction, bleeding, septicemia, hypoglycemia, metabolic acidosis and electrolyte disturbances due to renal tubulopathy (Fanconi syndrome). Progressive liver disease can result in cirrhosis of liver, hepatocellular failure or even death in undiagnosed patients. Patients may develop acute hepatocellular failure with ascites, jaundice and gastrointestinal bleeding. There is a high risk of developing hepatocellular carcinoma and hepatic nodules. Untreated patients usually die in infancy or early childhood.

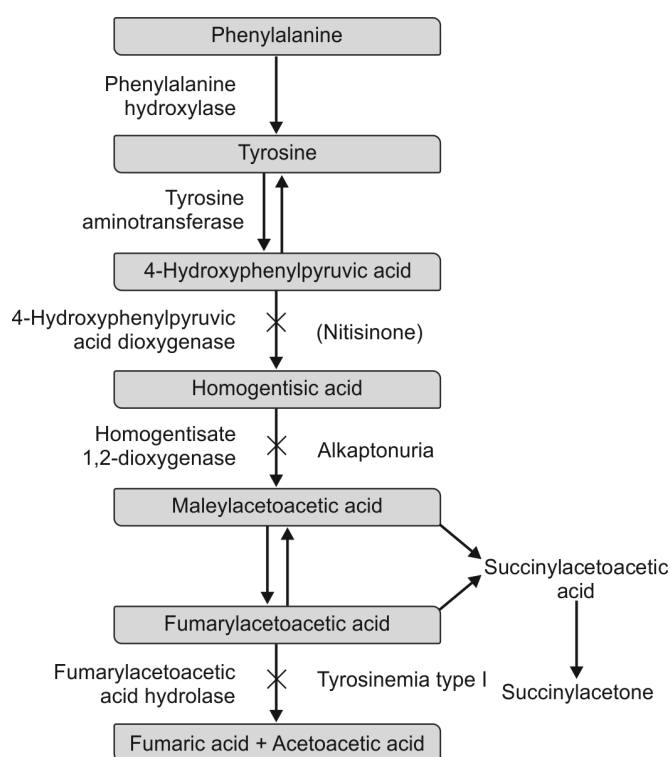

Chronic form of tyrosinemia type I presents with hepatomegaly, cirrhosis, growth retardation, rickets, hematoma, tubulopathy, neuropathy and neurological crises (due to porphyrins).

### Diagnosis

Presence of succinylacetone in urine or blood is diagnostic of tyrosinemia type I. Elevated levels of 4-hydroxyphenyl derivatives may also be seen in urine by GC-MS. Elevations of plasma tyrosine and methionine and occasionally generalized amino acidemia are seen in tyrosinemia type I. Alpha fetoprotein is elevated in serum and may serve as a marker for hepatocellular carcinoma/cirrhosis. Leukocytes, erythrocytes and liver tissues are deficient in FAH activity. Quantitative estimation of succinylacetone in amniotic fluid or FAH enzyme activity in chorionic villi cells may be used for prenatal diagnosis. But in our experience molecular diagnosis is the best method.

### Treatment

Patients with tyrosinemia type I must be treated aggressively with dietary restriction of tyrosine and phenylalanine along with administration of nitisinone (NTBC) [2(2-nitro-4-trifluoromethylbenzoyl)-1, 3-cyclohexanedione] in the dose of 1–2 mg/kg/day. This drug inhibits 4-hydroxyphenylpyruvate dioxygenase and blocks the accumulation of toxic metabolites. However, an increase

**Figure 5** Tyrosine metabolism

in tyrosine levels may be seen after administration of NTBC. Liver transplantation is another option as it provides normal FAH activity.

### TYROSINEMIA TYPE II AND TYROSINEMIA TYPE III

High tyrosine levels in blood may also be seen in other conditions like, transient tyrosinemia of the newborns, galactosemia, fructose intolerance, neonatal hepatitis, liver disorders, respiratory chain defects, bile acid synthesis disorders, etc.

Tyrosinemia type II is asymptomatic in the neonates but may cause hyperkeratosis of skin (soles and palms), painful corneal lesions (lacrimation, photophobia, scars) and mild intellectual disability. It is caused by the deficiency of cytosolic tyrosine amino transferase enzyme and diagnosed by increased levels of tyrosine and phenylalanine in blood and 4-hydroxyphenylacetate and 4-hydroxyphenylpyruvate in urine. Treatment for tyrosinemia type II is restriction of phenylalanine and tyrosine.

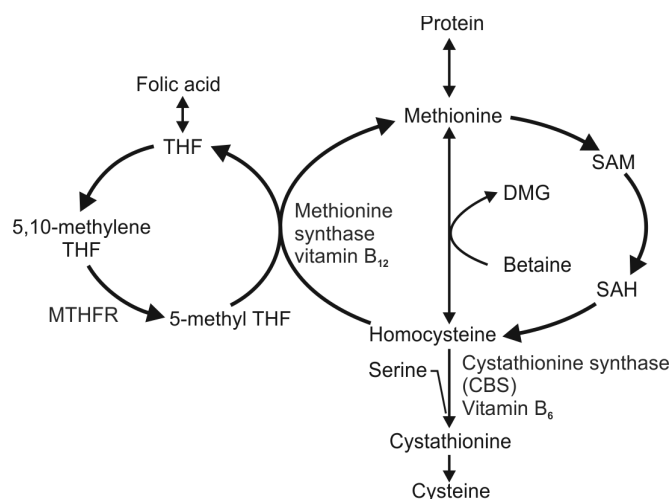

Tyrosinemia type III is caused by a deficient 4-hydroxyphenylpyruvate dioxygenase activity. However, the clinical relevance is uncertain and the disease may be benign.

### HOMOCYSTINURIA

Classic homocystinuria is a metabolic disorder of sulfur metabolism, caused by CBS (cystathionine-β-synthase) deficiency and inherited in autosomal recessive manner. There are two main phenotypes: a milder pyridoxine-responsive form, and a more severe pyridoxine-nonresponsive form. Pyridoxine works as a cofactor for the CBS enzyme, and aids in the conversion of homocysteine to cysteine (**Fig. 6**).

### Clinical Symptoms

Untreated classical homocystinuria (CBS deficiency) usually manifests in the first or second decade of life. Most common presentation is myopia and ectopia lentis. Some children also

**Figure 6** Homocysteine and methionine metabolism

suffer from mental retardation, marfanoid habitus (skeletal anomalies resembling Marfan syndrome), and sometimes thromboembolic events. However, in our experience, this is not a common manifestation. Milder variant of homocystinuria has also been reported characterized by increased plasma homocysteine and increased risk for thrombotic events in young adulthood, but without the other marfanoid features or ocular, or nervous system manifestations.

### Diagnosis

Increased levels of methionine, homocysteine ( $>150 \mu\text{mol/L}$ ), reduced cysteine and positive nitroprusside test are diagnostic of classic homocystinuria. Mutations in the CBS gene can be identified for the confirmation of the diagnosis.

### Treatment

For pyridoxine-dependent homocystinuria treatment is pyridoxine (50–100 mg/day). For nonresponsive patient's treatment involves strict methionine restriction along with anhydrous betaine (Tri Methyl Glycine—TMG) (100 mg/kg/day), hydroxycobalamin (1 mg/day), vitamin C (100 mg/day).

### NONKETOTIC HYPERGLYCINEMIA

Nonketotic hyperglycinemia (NKHG) is also known as glycine encephalopathy. It is an inherited metabolic defect with abnormally high blood and CSF glycine levels. The enzyme system for cleavage of glycine (glycine cleavage system; GCS) which is confined to the mitochondria, is composed of 4 protein components: **P** protein (GLDC) (a pyridoxal phosphate-dependent glycine decarboxylase); **H** protein (GCSH) (a lipoic acid-containing protein); **T** protein (AMT) (a tetrahydrofolate-requiring enzyme); and **L** protein (a lipoamide dehydrogenase). Mutations in the P, T and H proteins cause glycine encephalopathy.

### Clinical Symptoms

Almost 85% of glycine encephalopathies present in the neonatal period as a severe form. Overall, 20% of all children presenting as either neonates or infants have a less severe presentation. Atypical form or milder form is not so common. The severe neonatal form of encephalopathy presents in the first few hours to days of life. Progressive lethargy, hypotonia and myoclonic jerks are common presenting features; soon babies develop apnea and require ventilator support. Death is quite common in early neonatal period. Those who survive develop profound

intellectual disability and intractable seizures. The late onset infantile form is characterized by hypotonia, developmental delay, progressive neurological symptoms and seizures. The atypical forms may have milder disease, with onset varying from late infancy to adulthood, to even rapidly progressing severe disease of late onset.

### Diagnosis

Elevated glycine concentration in blood and CSF is the hallmark of the disease. An increase in CSF glycine concentration along with an increased CSF-to-plasma glycine ratio  $> 0.08$  (0.02–0.08) suggests the diagnosis. Enzymatic confirmation is possible by assay of glycine cleavage system (GCS) enzyme activity in liver. Mutations in T, P and H proteins can be identified as the cause of glycine encephalopathy.

**Newborn Screening** Tandem mass spectrometry is not a very good method to detect glycine encephalopathy in newborn screening. Many a times symptoms appear even before the results arrive.

### Treatment

There is no specific therapy for severe glycine encephalopathy. Early treatment with sodium benzoate to reduce plasma glycine concentration in the dose of 250–500 mg/kg/day and NMDA receptor blockers like dextromethorphan in the dose of 5–20 mg/kg/day may have better outcome than those treated late or untreated. Other supporting therapy like antiepileptic drugs, especially benzodiazepine group and/or ketogenic diet for seizure control is needed. For feeding nasogastric (NG) tube or gastrostomy (G button) may also be required. Physical therapy and treatment for gastroesophageal reflux may also be necessary. Folinic acid (15 mg/day) supplementation is also helpful.

### GYRATE ATROPHY OF CHOROID AND RETINA

Gyrate atrophy of the choroid and retina is caused by deficiency of ornithine aminotransferase. It is a triad of progressive chorioretinal degeneration, early cataract formation, and type II muscle fiber atrophy. It has been postulated that hyperornithinemia-induced deficiency of high-energy creatine phosphate leads to changes in skeletal muscle, as well as the ocular changes.

### Clinical Symptoms

It is manifested by chorioretinal atrophy and progressive constriction of the visual fields, which leads to blindness at the latest during the sixth decade of life. Patients generally have normal intelligence. By the end of second decade most of the patients have posterior subcapsular cataracts. Manifestations include myopia (in childhood), and impaired night vision progressing to blindness. Fundoscopy shows retinopathy (gyrate atrophy, increasing from the periphery). Atrophy of type II muscle fibers although asymptomatic in the beginning progresses slowly to complete loss of type II muscle fibers.

### Diagnosis

Ornithine levels in plasma, urine, CSF and aqueous humor are 10–20 times higher than normal. Hyperammonemia is uncommon (except occasionally in neonates). It is also associated with milder degree of phosphocreatine deficiency.

### Treatment

Dietary arginine is the main source of ornithine. Therefore, arginine restricted diet appears to be of therapeutic importance. Consider pyridoxine (40–200–600 mg/day), creatine monophosphate (up to 2 g/kg/day).

## DISORDERS OF AMINO ACIDS TRANSPORT

Process of transport of amino acids from intestine and from renal tubules back to circulation is energy dependent. For transport, enzymes are not required. They require special transport proteins embedded in cellular or intracellular organelle membranes. Thus, mutated proteins cause loss of certain amino acids in urine which are dependent on such transport system and lead to a specific disorders, e.g., cystinuria, lysinuric protein intolerance, Hartnup disease, etc.

### Lysinuric Protein Intolerance (LPI)

Defective cationic amino acid transport at the basolateral membrane of epithelial cells in kidney and intestine causes LPI. Characteristic metabolic abnormalities associated are increased renal excretion of amino acids, reduced amino acid absorption from intestine, and orotic aciduria. The gene involved in LPI is the amino acid transporter gene *SLC7A7*.

#### Clinical Symptoms

Clinical symptoms in LPI include diarrhea, vomiting and severe failure to thrive, hepatomegaly, cirrhosis, interstitial pneumonia, osteoporosis, renal failure, hemolysis and leukopenia. Symptoms are worsened by high protein intake and relieved by low protein diet. At times, LPI is complicated with HLH (hemophagocytic lympho-histiocytosis) syndrome. Some patients are reported to have symptoms like SLE (systemic lupus erythematosus).

#### Diagnosis

Low blood urea and hyperammonemia, along with increased LDH and ferritin is often observed. An increased urinary excretion of ornithine, arginine and lysine is observed but cystine excretion is normal. Plasma levels of these amino acids are low and especially arginine is significantly low affecting urea genesis, thus causing hyperammonemia.

#### Treatment

Low protein diet with citrulline supplementation is the therapy. It results in substantial increase in protein tolerance along with acceleration of linear growth and improvement in bone mass. Immunological abnormalities need special attention in this disorder.

### Cystinuria

Cystinuria is usually inherited as an autosomal recessive disorder but both recessive and dominant inheritances are suggested. There is a basic defect in the transport of cystine and dibasic amino acids lysine, ornithine, and arginine. Epithelium of proximal renal tubule and gastrointestinal tract are affected. Cysteine is not reabsorbed properly and it is also insoluble in water, resulting in formation of crystals and calculi. This in turn results in obstructive uropathy, pyelonephritis and renal failure. A classification has been proposed by Dello Strologo *et al.* (2002) based on the defective genes:

1. Type A—*SLC3A1* gene
2. Type B—*SLC7A9* gene
3. Type AB—*SLC3A1* and *SLC7A9* genes

#### Diagnosis

Onset is usually in the first or second decade. Besides nephrolithiasis, urinary infections are also common and may contribute to

renal failure. Type A (*SLC3A1* heterozygote) presents with excretion of large amounts of urinary amino acids, cystine, lysine, arginine and ornithine. Type B (*SLC7A9* heterozygotes) is characterized by moderate degree of amino aciduria, mainly cystine and lysine, and may occasionally form cystine stones.

#### Treatment

Treatment involves high fluid intake (> 5 L/day), alkalinization of the urine and penicillamine (1–2 g/day). Penicillamine is usually well tolerated without many side effects in these patients.

### Hartnup Disease

This autosomal recessive disorder was first described by Baron *et al.* (1956) and is caused by mutation in *SLC9A19* gene. It is often asymptomatic but may sometimes present with a pellagra-like light-sensitive rash; cerebellar ataxia; emotional instability; and aminoaciduria. Two forms were suggested by Scriver *et al.* (1985).

1. *Classic form* The defect is expressed in both intestine and kidney
2. *Variant form* It is expressed only in kidney.

#### Management

Increased excretion of neutral amino acids in urine (alanine, serine, threonine, valine, leucine, isoleucine, phenylalanine, tyrosine, tryptophan, glutamine and asparagine) is associated with normal-low neutral amino acids in plasma. Treatment involves nicotinamide administration (50–300 mg/day) and sun-protection.

### IN A NUTSHELL

1. Aminoacidopathies are the most common inborn errors of metabolism detected in India and hence they should always be kept in mind while screening of inborn errors of metabolisms.
2. Presentation of aminoacidopathies could be variable, involving purely neurological or hepatic or combined symptoms. They may also present with failure to thrive and rickets.
3. Plasma or serum amino acid screening should be the first choice and not only urine. However, a combination of plasma and urine amino acids gives a better understanding of the pathology.
4. Collection of the sample, timing in relation to feeds, transportation in appropriate tubes and at appropriate temperatures are the preanalytical factors that can affect results and interpretation.
5. Use of the best available quantitative estimation method and interpretation in relation to the age of the patient by an experienced metabolic physician cannot be overemphasized.
6. Some conditions are episodic (e.g., MSUD) and repeated sampling and testing may be required if clinical suspicion is very high.
7. Elimination of offending amino acids or supplementing the essential amino acids or both may form the corner-stone of the therapy.

## Chapter 3.3

# Urea Cycle Disorders

Sunita Bijarnia-Mahay

The urea cycle, first described by Krebs and Henseleit in 1932, is an extremely important enzymatic process in humans and terrestrial animals as it is the only pathway for detoxification of ammonia, the toxic product of breakdown of protein and other nitrogen containing molecules. Disorders that directly or indirectly affect the urea cycle disrupt the detoxification process, and lead to hyperammonemia with consequent toxic brain injury and death. Thus, it is important to recognize these disorders early for any possible intervention and treatment.

The urea cycle is exclusively present in the hepatocytes, distributed between the mitochondrial matrix and the cytosol. The urea cycle enzymes are activated only after either excess nitrogen load (high protein diet) or excess breakdown of protein within the body. The five catalytic enzymes and three other proteins taking part for smooth functioning of the urea cycle are described in the chapter.

## EPIDEMIOLOGY

The worldwide incidence of urea cycle disorders (UCD) is approximately 1 in 25,000–30,000 livebirths. While these disorders are commonly encountered in most of the tertiary care centers in India, and recognized because of hyperammonemia, their exact prevalence is not known.

Worldwide, ornithine transcarbamylase (OTC) deficiency is the most common defect (1:15,000), but in our experience in India, citrullinemia type 1 is by far the most common among neonatal classical presentations. This is followed by children with OTC and argininosuccinate lyase (ASL) deficiency. It is possible that a lot of OTC deficiency patients, especially girls are being missed out. Deficiency of carbamoyl phosphate synthetase (CPS1) and N-acetylglutamate synthase (NAGS) have not yet been diagnosed in the Indian sub-continent. This may be due to the unavailability of gene studies for these disorders.

## ETIOLOGY

All the urea cycle enzyme defects are genetically determined, caused by mutations in genes coding for enzymes, cofactor producer or transporter proteins of the urea production pathway. All UCDs are autosomal recessively inherited, except for OTC which is inherited in an X-linked pattern. OTC deficiency may manifest in females frequently (in up to 15% cases), although with less severity than males. The symptoms in a female carrier depend on the degree of skewed inactivation of the X chromosome.

## PATHOGENESIS

### The Urea Cycle

Ammonia is produced by deamination of amino acids in liver, other tissues as well as from gut bacteria. Whatever its source, the ammonia reaching the liver is immediately used to form urea. The urea cycle begins within the mitochondrial matrix of hepatocytes by formation of carbamoyl phosphate by a combination of ammonia with bicarbonate requiring two molecules of ATP, catalyzed by enzyme, CPS1 (**Fig. 1**). The enzyme CPS1 requires N-acetylglutamate for its activation, which itself is synthesized from acetyl CoA and glutamate by enzyme, NAGS. Thus, for initiation of the urea cycle, both CPS1 and NAGS are required (as a cofactor). Hyperammonemia is a direct effect of either deficiency of these

two enzymes, or indirect effect caused by suppression of NAGS as in many of the organic acidemia.

Carbamoyl phosphate then condenses with ornithine and forms citrulline in presence of enzyme, OTC. Ornithine enters the mitochondria by the ornithine transporter (ORNT). Disorders at these levels are caused either by deficiency of the enzyme OTC, or the transporter defect, ORNT. Citrulline is then transported out of the mitochondrial matrix into the cytosol for proceeding with the cytosolic component of the urea cycle (**Fig. 1**).

Alternate mechanisms of detoxification of ammonia are utilized in treatment of hyperammonemia. Conjugation of sodium benzoate with glycine to form hippurate, and conjugation of phenylbutyrate (converted to phenylacetate) with glutamine generate phenylacetylglutamine. Both these compounds are nontoxic and excreted in the urine, thus enabling removal of waste nitrogen from body.

## Mechanism of Central Nervous System Toxicity in Hyperammonemia

The main reason for sickness in urea cycle enzyme defects is the progressive accumulation of toxic levels of ammonia. Thus, the clinical presentation is primarily neurologic, whether it is in neonatal period or later in life. Hyperammonemia is toxic to the brain both in the acute severe form as well as in chronic elevated form.

The acute symptoms are caused by progressive cerebral edema because of elevated ammonia. At the cellular level, high ammonia causes astrocyte swelling and loss of neuronal function. Secondary metabolic derangements include elevation of glutamine, a buffer for excess nitrogen, causing osmotic brain edema triggering apoptosis, arginine deficiency causing a decrease in nitrous oxide, and creatine synthesis, further leading to neuronal damage.

Chronically, hyperammonemia can lead to progressive cortical atrophy, lesions in the basal ganglia, delayed myelination and cystic changes—all leading to developmental delay, seizures and progressive cognitive impairment.

The extent of central nervous system damage depends on both severity and duration of hyperammonemia. Newborn and infantile brains are the most vulnerable to irreversible neurological damage. The prognosis is bad even with treatment of hyperammonemia in these ages.

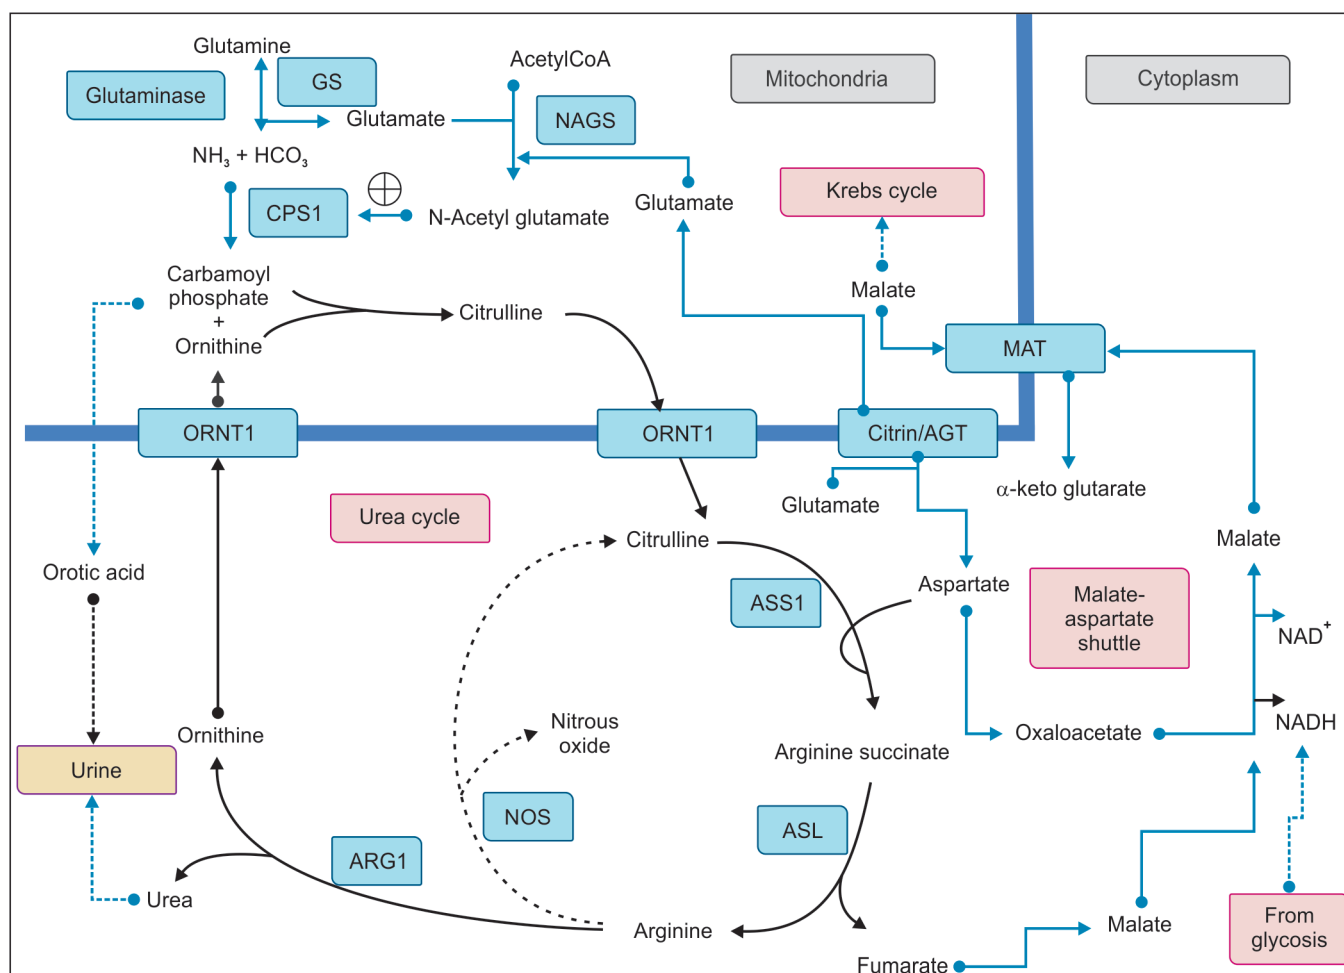

## CLINICAL PRESENTATION

The severity of enzyme deficiency is the key to the clinical severity. Severe deficiency or total absence of enzyme activity leads to classical neonatal presentation with hyperammonemia with ensuing coma and death, if untreated. This presentation is classical for severe deficiency of any of the first four enzymes of urea cycle (CPS1, OTC, NAGS, and ASL, i.e., up to formation of arginine). Less severe deficiency may result in episodic presentation later in life because of hyperammonemia in acute stressful conditions such as intercurrent illnesses and fasting. The deficiency of the fifth enzyme, arginase 1 (ARG1), and two transporters, ornithine and aspartate transporter leads to different clinical presentations. Only the common defects are discussed in this chapter.

## Clinical Presentation of Deficiency of the Initial Four Enzymes of the Urea Cycle and One Cofactor Producer

### Neonatal Classical Presentation

The neonates appear normal at birth and present within the first week, mostly within first 48–72 hours of life with progressive lethargy, and refusal to feed. This coincides with increase in oral

**Figure 1** The urea cycle with its links with the other pathways—nitrous oxide synthesis, malate-aspartate shuttle, glycolysis and Krebs cycle  
 Abbreviations: GS, glutamine synthase; NAGS, N-acetyl glutamate synthetase; CPS1, carbamoyl phosphate synthetase 1; ORNT1, ornithine transporter 1; AGT, aspartate glutamate transporter, also called citrin; MAT, malate  $\alpha$ -ketoglutarate transporter; ASS, argininosuccinate synthetase; ASL, argininosuccinate lyase; ARG1, arginase 1; NOS, nitrous oxide synthetase; NADH, nicotinamide adenine dinucleotide; Black arrows, urea cycle; Blue arrows, linked pathways; Dotted arrows, not showing complete pathways, only directing toward them.

intake of protein, as well as with ongoing catabolism and stress of birth. As stage advances, the babies may have irritability, vomiting, tachypnea (because of cerebral hyperventilation), and seizures in 50%, as a sign of neurotoxicity. There are no other metabolic derangements initially, apart from hyperammonemia. Later, there can be apnea owing to reduced respiratory drive, metabolic acidosis (especially in argininosuccinic aciduria or ASL deficiency), hypoglycemia (neurotoxicity), hypothermia and lactic acidemia as encephalopathy deepens. Progressive coma and death ensues, if untreated, accompanied by brain stem herniation.

### Delayed Onset

The affected individuals have a varied disease-free or crisis-free period, ranging from months to years, depending on the enzyme level and circumstances leading to hyperammonemia. The diagnosis is most often delayed as minor hyperammonemic episodes go unnoticed, and produce a cumulative effect on the neurological development of the child. Sometimes, children can be asymptomatic until a trigger sets in hyperammonemia, like drugs (Valproate), acute severe infections, starvation or any catabolic state. This can happen any time during the lifetime of the individual. Children may also present with physical failure to thrive with liver dysfunction, especially in citrullinemia type 1 or 2 and ASL

deficiency. Some children show self-restriction of protein in diet.

Particularly for ASL deficiency, manifestations that appear to be unrelated to the severity or duration of hyperammonemic episodes include: (1) neurocognitive deficiencies (attention deficit hyperactivity disorder, developmental disability, seizures, and learning disability); (2) liver disease (hepatitis, cirrhosis); (3) trichorrhexis nodosa (coarse brittle hair that breaks easily); and (4) systemic hypertension.

Deficiency of OTC in females results in clinical manifestations in about 15% girls. It has now been recognized that carrier females may have deficiencies in executive function, even when they may never have had symptoms of overt hyperammonemia.

## Clinical Presentation for Other Enzyme and Transporter Defects

### Arginase Deficiency

Clinical presentation in children with arginase deficiency is not typically because of hyperammonemia, although they can occur in severe episodes leading to death. In infancy, there may be irritability and failure to thrive. This is followed by development of spasticity, plateauing of cognitive development, and subsequent loss of developmental milestones. The age of onset and symptoms

vary with degree of enzyme deficiency. As the symptoms advance, the children have progressive spasticity leading to complete loss of ambulation, autonomic dysfunction with loss of bowel/bladder control and severe cognitive impairment.

### Citrin Deficiency (Aspartate Glutamate Transporter Defect)

Citrin deficiency is unique because of its varied clinical presentation at different ages. It leads to disruption of not only the urea cycle but also other energy producing pathways like glycolysis and Krebs cycle. Clinically, it can manifest in newborns as neonatal intrahepatic cholestasis caused by citrin deficiency (NICCD), in older children as failure to thrive and dyslipidemia caused by citrin deficiency (FTTDCD), and in adults as recurrent hyperammonemia with neuropsychiatric symptoms in citrullinemia type II. The neonatal form, NICCD manifests with neonatal intrahepatic cholestasis, characterized by metabolic derangements like hypoglycemia, hyperammonemia, hemolytic anemia and cataracts. The disease remits spontaneously by 12 months of age after which body starts to self-control the diet. Often citrin deficiency is characterized by fondness for protein-rich and/or lipid-rich foods and aversion to carbohydrate-rich foods. Although citrin deficiency is most often described in oriental population, but it has increasingly been reported from other parts of the world.

## DIAGNOSIS AND APPROACH

The diagnosis of UCD starts a high index of suspicion—in every sick baby or child! The family history is very important as it may provide vital clues, especially in X-linked pedigree pattern or presence of consanguinity and previous neonatal deaths. With this background and high index of suspicion, the only important investigation in a child presenting with clinical symptoms described above is a plasma ammonia level.

Precautions taken for sample collection for plasma ammonia: There are practical issues with collection of blood for plasma ammonia levels. Ideally, this should be taken as a free-flowing blood sample and transported to the laboratory within minutes (ideally < 15 minutes), and on ice so that the spontaneous production of ammonia from deamination of glutamine in red blood cells is reduced to a minimum. Thus, the facilities for testing ammonia should be present in every major hospital, and there should be a system of transporting the blood drawn immediately on ice to the concerned laboratory.

If child is sick, clinicians must start therapy on grounds of suspicion alone and not wait for ammonia levels to come. It must be emphasized here that neonates typically have higher ammonia levels normally, thus the normal range for ammonia in plasma for a term neonate is less than 110  $\mu\text{mol/L}$  (in preterms the normal level is < 150  $\mu\text{mol/L}$ ), and less than 80 for infant under 1 year, reaching the adult range of less than 35  $\mu\text{mol/L}$  only after infancy. In general, plasma ammonia level more than 150 in neonates and infants and more than 100  $\mu\text{mol/L}$  in older age is to be considered significant to warrant further action. Additionally, indirect evidence of hyperammonemia can be detected on neuroimaging with MRI scans showing features of cerebral edema.

Apart from ammonia, the other relevant tests to be done include arterial blood gas, anion gap, blood lactate, acylcarnitine (by tandem mass spectrometry), plasma and urine amino acids, and urine organic acid analysis (specifically for orotate).

An algorithm for approach to hyperammonemia is provided in **Flow chart 1**. Typical urea cycle defect children will have normal glucose, electrolytes and lactate. The pH and  $\text{CO}_2$  varies with stage of neurotoxicity and cerebral edema. Once the results of these tests are available, one can follow the algorithm described to come to a

diagnosis. Once clinically suspected and biochemically diagnosed, a definitive diagnosis of a urea cycle defect depends on either molecular genetic testing or measurement of enzyme activity. Molecular genetic testing is possible for all urea cycle defects (**Table 1**).

## DIFFERENTIAL DIAGNOSIS

The differential diagnosis for UCD is mainly conditions that give rise to hyperammonemia which are listed in the **Table 2**. A quick guide to bedside diagnosis is provided in **Table 3**, based on basic investigations. Other than hyperammonemia, disorders like citrullinemia type 1, citrin deficiency and argininosuccinic aciduria present with liver dysfunction, which need to be differentiated from other inherited or acquired causes of cholestasis and liver disease. Arginase deficiency and hyperornithinemia-hyperammonemia-homocitrullinuria (HHH) syndrome often present with spasticity, thus making it difficult to differentiate from other causes of spasticity like spastic diplegia as sequelae of perinatal asphyxia or hereditary spastic paraparesis.

## MANAGEMENT

Immediate treatment is to be initiated in hyperammonemia to prevent and minimize the drastic neurological consequences. Four principle aims of management are:

1. Immediate ammonia detoxification from body fluids
2. Inhibition of production of ammonia further in body
3. Providing hemodynamic stability, by correction of fluid or electrolyte and acid-base imbalance in the body
4. Treatment of underlying cause of acute deterioration—sepsis or trauma, etc. which triggered the metabolic decompensation.

### Immediate Treatment

Emergency management of acute presentation is summarized in **Box 1**. The most important and most urgent of all is a rapid correction of ammonia. The decision to start therapy is purely clinical, but generally, any ammonia more than 150  $\mu\text{mol/L}$ , especially in a sick neonate/child or adult should be taken seriously and treated immediately.

In view of the rarity of presentation, treatment must be coordinated by a metabolic center with experience in UCD, and whenever possible, shifted to a tertiary care center with intensive care unit (ICU) facilities. Immediate steps to be taken before shifting to higher center are:

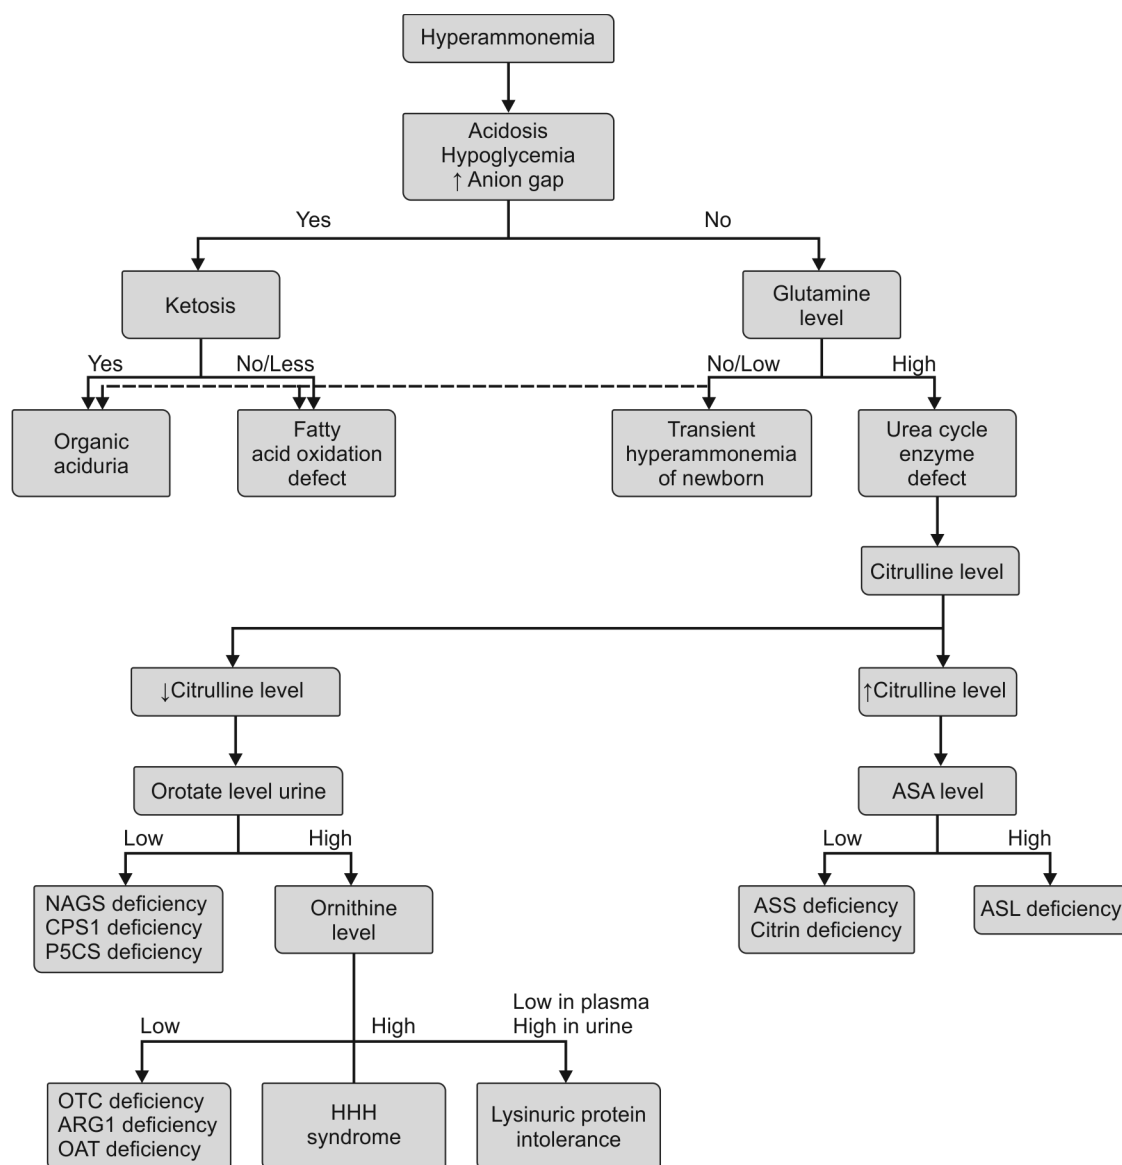

- Stop all oral intake of protein (but only for 24 hours, followed by gradual introduction of small amounts)
- Start intravenous (IV) 10% glucose infusion
- Initiation of first-line medications—ammonia scavengers like oral sodium benzoate powder
- Collection of blood and urine samples for diagnostic purposes and appropriately transporting to laboratory concerned.

Specific testing should go hand-in-hand with initiation of therapeutic measures so that a quick and accurate diagnosis is achieved in minimum possible time. Once at tertiary care center, the treatment of acute severe hyperammonemia should be as follows as per the principle aims listed above.

### Ammonia Detoxification

The child should be started on ammonia scavengers if not started by that time, and a decision for hemodiafiltration taken depending upon the ammonia level on arrival (indications: ammonia > 500  $\mu\text{mol/L}$  or rapidly rising).

**Sodium benzoate** It is the only medicine that is freely available as oral preparation/powder in India and this should be used as soon as hyperammonemia is detected. Dose of oral sodium benzoate

**Flow chart 1** The algorithm showing approach to diagnosis of urea cycle disorder based on biochemical tests

Abbreviations: NAGSD, N-acetyl glutamate synthetase deficiency; CPS1D, carbamoyl phosphate synthetase 1 deficiency; OTCD, ornithine transcarbamoylase deficiency; ARGD, arginase deficiency; OATD, ornithine aminotransferase deficiency; HHH, hyperammonemia-hyperornithinemia-homocitrullinemia; ASS1D, argininosuccinate synthetase 1 deficiency; ASLD, argininosuccinate lyase deficiency; LPI, lysinuric protein intolerance.

is 250 mg/kg/day, divided at 6–8 hourly intervals. This may be increased up to 500 mg/kg/day if required. Ideally, in a sick child, intravenous bolus infusions of sodium benzoate should be given at similar doses at 6-hourly intervals.

**Sodium phenylbutyrate/sodium phenylacetate** Phenylbutyrate is a precursor of phenylacetate and more palatable than phenylacetate. Available outside India as tablets, given in doses similar to sodium benzoate of 250–500 mg/kg/day divided in 3 or 4 doses. In developed countries, a combination of IV sodium benzoate and sodium phenylacetate (Ammonul®) or with sodium phenylbutyrate (Ammonaps®) is available.

**Arginine and citrulline** Arginine and citrulline are used to promote waster nitrogen excretion. Arginine helps in maximizing ammonia excretion through urea formation. It is also an amino acid that becomes essential especially when urea cycle is not functioning. Thus, it needs to be supplemented to avoid deficiency of arginine

affecting nitrous oxide and creatine synthesis. Dose for arginine in acute emergency (as intravenous) is 360 mg/kg in 2 hours followed by 180–360 mg/kg/day, depending on type of UCD, divided in intervals of 6–8 hours. Arginine is only available as sachets in India containing powdered form. Oral dose of arginine is the same as IV doses per day. Arginine should not be used in arginemia and is not effective in OTC deficiency. Citrulline is not easily available and, therefore, not given.

**N-carbamoylglutamate (Carbaglu®)** This product is extremely helpful in NAGS deficiency as it mimics N-acetylglutamate and helps activation of the CPS1 enzyme to start the urea cycle. Carbamoyl glutamate can also be used in hyperammonemia in organic aciduria, as there is secondary inhibition of NAGS by organic acids. Dose is 100 mg/kg orally/24 hours in three divided doses. The use of this drug is limited due to its high cost and nonavailability here in India.

**Table 1** Diagnostic features and genes related with urea cycle disorders

Disorder	Gene	Inheritance pattern	Plasma amino acid concentrations	Urinary orotic acid levels	Diagnostic modality
N-acetyl glutamate dehydrogenase deficiency (NAGS deficiency)	NAGS	AR	↑↕ Glutamine ↑ Alanine	Normal	Enzyme assay (liver) or gene study
Carbamoyl phosphate synthetase deficiency (CPS1 deficiency)	CPS1	AR	↑ Glutamine ↑ Alanine ↓ Citrulline ↓ Arginine	Normal	Enzyme assay (liver) or gene study
Ornithine transcarbamoylase deficiency (OTC deficiency)	OTC	X-linked	↑ Glutamine ↑ Alanine ↓ Citrulline ↓ Arginine	↑↑	Enzyme assay (liver) or gene study
Argininosuccinate synthetase deficiency (ASS deficiency or citrullinemia type 1)	ASS1	AR	↑ Glutamine ↑ Alanine ↑↑ Citrulline ↓ Arginine	↑	Enzyme assay (liver, skin fibroblasts) or gene study
Argininosuccinate lyase deficiency (ASL deficiency or argininosuccinic aciduria, ASA)	ASL	AR	↑ Glutamine ↑ Alanine ↑ Citrulline ↑↑ Arginino-succinate ↓ Arginine	↑	Enzyme assay (liver/skin fibroblasts/RBCs) or gene study
Arginase deficiency (hyperarginemia)	ARG1	AR	↑ Arginine	↑	Enzyme assay (liver/RBCs) or gene study
Aspartate-glutamate carrier deficiency (citrin deficiency, citrullinemia type 2, NICCD in neonates)	SLC25A13	AR	↑ Glutamine ↑ Alanine ↑/N Citrulline ↓ Arginine	↑	Gene study
Ornithine transporter deficiency (HHH syndrome)	SLC25A15	AR	↑ Ornithine ↑ Homocitrulline in urine	↑	Gene study

Abbreviations: AR, autosomal recessive; HHH, hyperornithinemia-hyperammonemia-homocitrullinuria; NICCD, neonatal intrahepatic cholestasis caused by citrin deficiency.

**Table 2** Causes of hyperammonemia

Inherited deficiency of enzymes of urea cycle	N-acetyl glutamate synthetase deficiency Carbamoyl phosphate synthetase deficiency Ornithine transcarbamoylase deficiency Argininosuccinate synthase deficiency (citrullinemia type 1) Argininosuccinate lyase deficiency (argininosuccinic aciduria) Arginase deficiency (argininemia)
Inherited defect of transporters affecting the urea cycle intermediates	Ornithine transporter (HHH syndrome) Dibasic amino acid transporter (lysinuric protein intolerance) Citrin or aspartate—glutamate transporter (citrullinemia type 2)
Inherited deficiency of enzymes of other metabolic pathways	Organic aciduria (propionic acidemia, MMA and others) Disorders of fatty acid oxidation (MCADD, primary carnitine deficiency, etc.) Hyperinsulinism/hyperammonemia syndrome Ornithine aminotransferase deficiency (neonatal form) Mitochondrial respiratory chain defects Pyruvate dehydrogenase deficiency Pyruvate carboxylase deficiency (neonatal form)
Acquired causes	Liver failure/impairment Any severe systemic illness in neonate Gastrointestinal bacterial overgrowth Urinary tract infections Drugs: e.g., valproate, chemotherapy Total parenteral nutrition Reye's syndrome
Other causes	Artificial preanalytical increase: Poor specimen quality/hemolysis Difficult venipuncture Skin contamination Contaminated tube Delayed analysis and inappropriate transport to lab without ice Transient hyperammonemia of the newborn Portosystemic shunt

Abbreviations: HHH, hyperornithinemia-hyperammonemia-homocitrullinuria; MCADD, Medium-chain acyl-CoA dehydrogenase deficiency; MMA, methylmalonic acidemia.

**Table 3** Differential diagnosis of urea cycle disorders using baseline investigations

Parameter	Urea cycle disorder	Organic aciduria	Carnitine/fatty acid oxidation disorder	Mitochondrial disorders (Pyruvate carboxylase/dehydrogenase/respiratory chain disorders)	Hyperinsulinism/hyperammonemia syndrome	Transient hyperammonemia of newborn
Ammonia	++/++++	++/+++	++	++	++	++++
Acidosis	+/-	+	+/-	+	-	-
Ketosis	-	++	-	N/++	-	-
Lactate	N	N/++	N/++	++/+++	N	N
Glucose	N	N/↓	↓	N/↓	↓	N
AST/ALT	N/D	N	N/D	N/D	N	N
WBC/RBC	N	N/↓	N	N	N	N

Ammonia: + (< 200 μmol/L), ++ (200–600), +++ (> 600), ++++ (> 1,500)

Abbreviations: N, normal; D, deranged; ↓, low.

### BOX 1 Emergency treatment of severe acute hyperammonemia

1. Basic life support and supportive treatment, e.g., ventilation (particularly prior to transfer) treatment of sepsis, seizures, etc.
2. Stop protein intake
3. Provide high-energy intake
  - Orally (if accepting): 10–25% sugar or juice, protein-free formula (special dietary formula)
  - Intravenous: 10% glucose by peripheral infusion, or 10–25% glucose by central venous line, IV intralipid infusion 2–4 g/kg/24 hours
4. Ammonia detoxification
  - Sodium benzoate up to 500 mg/kg/day—oral or IV
  - Sodium phenylbutyrate up to 600 mg/kg/day
  - L-arginine 50 up to 600 mg/kg/day depending upon disorder (contraindicated in arginase deficiency)
5. Dialysis (hemodialysis, hemodiafiltration or hemofiltration)
  - Start immediately if plasma ammonia more than 500 μmol/L or if ammonia does not fall with the above measures
  - Peritoneal dialysis in neonate.

**Dialysis** In acutely sick babies and children with rapidly increasing or very high levels (> 500 μmol/L) of ammonia, this invasive but very effective procedure of extracorporeal detoxification is employed. Hemodialysis is superior to all other forms of dialysis, resulting in more than 50% reduction in ammonia levels within hours. Continuous high-volume venovenous hemodiafiltration (CVVH) can be used very effectively due to its availability in most advanced ICUs in India.

### Inhibition of Ammonia Production

**Increase calorie supplementation to offset catabolism and protein breakdown** Provide 10–20% glucose infusion and add insulin if hyperglycemia occurs. IV lipids infusion @ 2–3 g/kg/24 hours is also helpful.

**Stop all natural protein intake (in diet) to reduce the ammonia production initially** The duration of *nil protein* intake should not exceed 24–36 hours as it causes tissue breakdown to meet protein demands. Thereafter little amount of protein is initiated either orally or parenterally, and titrated up to maintain anabolism as well as to keep the ammonia levels down.

### Correction of Fluid and Electrolyte/Acid-Base Disturbance

In the acute state, there is often dehydration because of vomiting and reduced oral acceptance, which needs immediate attention. Electrolytes need to be monitored as the drugs used for ammonia detoxification themselves have sodium (1 g of

sodium benzoate contains 7 mmol of Na<sup>+</sup>; thus, the sodium intake needs to be monitored). Respiratory alkalosis accompanying hyperammonemia does not need correction most of the time.

### Treatment of Underlying or Triggering Factors

A full diagnostic work-up and prompt and aggressive treatment should be initiated to combat the underlying cause, which in most cases is an infection especially in older infants and children.

### Long-term Management

#### Dietary Management

The basis of dietary management is to prevent production of ammonia. This is achieved by keeping the protein intake to the lowest required level, which is enough to sustain linear growth and carry out all the cellular functions appropriately. Thus, if the body is maintained in positive nitrogen balance (protein synthesis greater than protein breakdown), the ammonia will not be generated and urea cycle may not be initiated. The protein requirement can be ascertained on the basis of age, weight and physical health of an individual. The minimum dietary protein requirement can be met in a vegetarian diet, but this may be deficient in calories and vitamin/minerals and trace elements. Thus, extra carbohydrate or fats, vitamins and other trace element supplements need supplementation. Special diets, containing essential amino acids are available that take care of the requirement of quality protein and vitamin/trace elements.

#### Drug Therapy

The same ammonia scavenging medications (generally sodium benzoate and arginine) need to be continued, with regular monitoring of ammonia levels. The doses vary with every child's requirement and should be modified according to ammonia levels from time to time.

### Management of Acute Intercurrent Illnesses/Other Stressful Situations—Emergency Protocols for Home and Hospital

Any acute illness like viral fever or sore throat is an added stress on the body, with increased demand for energy leading to a catabolic state if oral intake is poor. In order to circumvent this stress, the body needs extra energy with no extra protein intake to reduce production of more ammonia. Thus, a careful balance of reduced protein intake coupled with extra calories in the diet is required for a few days. This can be managed safely at home, for minor illnesses. The family should be informed of danger signs when the child requires hospital management. Thus, protocols for both

home management (*sick day regime*) and hospital emergency department should be provided to the family.

### Monitoring for Growth and Development

Regular assessment of growth and development is required to assess appropriateness of dietary protein and energy intake of patient. In addition, few blood parameters, such as hemoglobin, albumin and pre-albumin levels, vitamins and amino acid levels, should be checked regularly to assess growth and efficacy and adequacy of maintenance therapy. Ammonia should be monitored more frequently both in normal state as well as during times of acute illness.

### Supportive Treatment

As most of the children are diagnosed with UCD after an acute illness, it is usual to find various degrees of neurological sequelae and developmental delay in these children. A multidisciplinary approach is recommended which would take care of the child's all round development. Anticonvulsants may be required for seizures, but valproate therapy should be avoided as valproate itself can cause hyperammonemia.

### Liver Transplantation as an Option for Long-term Cure

Over the last two decades, reasonable evidence has gathered that liver transplantation is the only modality that provides a definitive cure to patients of UCD. Long-term (5-year) survivals are now close to 90% with minimum morbidity, if offered at a time when the child has not had many neurological insults. The quality of life improves as child is allowed a limitless diet of choice, and reduction in hospital admissions. However, lifelong immunosuppressant therapy is required which may be a deterrent for few patients, along with the exorbitant cost of a liver transplant.

### OUTCOME

Irrespective of the treatment, the outcome of acute severe neonatal presentation of UCD remains poor. Only a few neonates who are picked up early before elevation of ammonia to toxic levels, and siblings of affected children do well with timely initiation of appropriate therapy. Outcome of children presenting later is better, provided the hyperammonemic episodes are briskly and effectively managed and continued in the long-term.

### PREVENTION

As all the UCDs are inherited, prenatal diagnosis is feasible and available in India, and is recommended to all couples that have had a child with UCD. Relatives at risk also can be screened for carrier status by gene studies followed by appropriate genetic counseling

regarding risk to their offsprings. Prenatal diagnosis is carried out using mutation analysis (only in cases where the causative mutation is known) after chorionic villus sampling at 11–13 weeks of pregnancy.

### IN A NUTSHELL

1. Urea cycle is the only metabolic pathway utilized for detoxification of ammonia and disposal of nitrogen waste.
2. Disruption of this cycle or urea genesis, either directly or indirectly, leads to progressive accumulation of toxic ammonia in the body.
3. Hyperammonemia is an absolute emergency condition as if not detected promptly; it can lead to progressive neuronal damage and death.
4. Very high index of suspicion should be kept and ammonia levels should be checked in any sick neonate or child who presents with neurological symptoms.
5. Treatment of UCD is based on low-protein diet as well as drugs to provide alternate pathway for waste nitrogen disposal (sodium benzoate, sodium phenylbutyrate).
6. Some new innovative therapies are available now, like carbamoyl glutamate for children with NAGS deficiency, and liver transplantation as a one-time treatment.
7. Urea cycle disorders are genetic in origin; each being inherited either in autosomal recessive or X-linked manner. More severe genetic defects lead to presentation as early as few days of life, and some may present even in adulthood.
8. Genetic testing and prenatal diagnosis is available for all the UCDs.

## Chapter 3.4

# Organic Acidemias

Neerja Gupta

Organic acidemias refer to an inborn error of metabolism (IEM) characterized by urinary excretion of the nonamino organic acids. The clinical presentation is often nonspecific, highly variable and requires high index of suspicion by pediatricians and neonatologists. Classically, patients with severe forms will present acutely in the neonatal period, as a sepsis like illness with encephalopathy, vomiting, poor feeding, seizures or lethargy after an initial asymptomatic period. Children with milder forms manifest over a long period of time but sometimes with acute episodes.

Exact prevalence of organic acidemia is not known due to lack of newborn screening program. In author's experience and based upon other Indian studies, organic acidemias appear to be one of the most common IEMs in India.

## PATHOGENESIS

Organic acidemia is a broad term where deficiency of specific enzyme in amino acid metabolism, mitochondrial disorders,  $\beta$ -oxidation of fatty acids or carbohydrate metabolism results in abnormal urinary excretion of organic acids. Most organic acids are carboxylic acids derivatives and are the byproducts of several metabolic pathways (**Fig. 1**). Organic acids are generated as a result of first transamination step and second dehydrogenation step of amino acid catabolism. Most organic acidemias are due to a downstream defect in the catabolism of branched-chain amino acids (BCAA). Any block in their breakdown leads to the accumulation of organic acids in the cell and its elevation in plasma and urine. These accumulated organic acids are either toxic themselves or metabolized to other toxic byproducts affecting function of various major organs. Organic acidemias are characterized by the presence of metabolic acidosis with increased anion gap in combination with hyperammonemia, hypoglycemia, hypocalcemia, ketosis or lactic acidosis.

Most of the affected babies are delivered as healthy term babies as during pregnancy placenta acts as a dialyzer for removing the accumulated toxic metabolites. After birth, the combination of initial catabolic state and initiation of feeds result in precipitation of clinical symptoms. These episodes of metabolic decompensation are precipitated by catabolic states, such as fasting, infections and fever. Diagnosis is possible by using gas chromatography-mass spectrometry (GCMS) as it can detect the typical urinary organic acids profile seen in various organic acidurias. Majority of these disorders have autosomal recessive inheritance. Based upon the deficiency of enzyme, the common organic acidemias are maple syrup urine disease (MSUD), propionic acidemia (PA) and methylmalonic acidemia (MMA), glutaric acidemia type 1 (GA-1) and isovaleric acidemia (IVA). Other rare disorders are biotin-unresponsive 3-methylcrotonyl-CoA carboxylase

deficiency, 3-hydroxy-3-methylglutaryl-CoA (HMG-CoA) lyase deficiency, mitochondrial acetoacetyl-CoA thiolase deficiency (3-ketothiolase deficiency) and 3-methylglutaconic acidurias. **Figure 2** shows the pathway of BCAA catabolism leading to various organic acidemia.

## CLINICAL FEATURES

Typical presentation includes neonates with vomiting, poor oral acceptance, lethargy, tone abnormalities or seizures rapidly progressing to encephalopathy at around 7–10 days of life. Presence of a positive family history, consanguinity, history of previous neonatal death with similar illness provides an important clue to the diagnosis. Although physical examination of babies with organic acidemia is unremarkable, yet there are certain clues (**Table 1**) that can point toward a specific diagnosis. Accumulation of organic acid can give rise to a peculiar odor of the urine or sweat.

Older children present with failure to thrive, developmental delay with or without convulsions, regression, static or progressive dystonia, or choreoathetoid movements. They may also present with acute decompensation precipitated by starvation or intercurrent illness.

## INVESTIGATIONS

### Basic Metabolic Screen

Measurement of blood glucose, electrolytes, pH for acidosis, lactate levels, ammonia levels and urinary ketones give a fair clue toward underlying organic acidemia. Salient features of most organic acidemias are discussed further:

- **Metabolic acidosis** Accumulation of organic anions, lactate or ketones result in metabolic acidosis with increased anion gap ( $>20$  mmol/L).
- **Lactic acidosis** Normal blood lactate levels 0.5–1 mmol/L; abnormal greater than 2 mmol/L.
- **Ketosis** Presence of ketones in a sick newborn is an alarming sign as neonates normally do not produce any ketones. A simple bedside positive urinary dipstick test for ketones (acetoacetic acid and acetone) in a sick baby presenting with acute encephalopathy gives a clue toward the diagnosis of organic acidemia and should be promptly followed by GCMS.
- **Hyperammonemia**

There may be associated abnormal liver function test, hypo- or hyperglycemia, hypocalcemia, thrombocytopenia or neutropenia. The basic approach to a child with organic acidemia is shown in **Flow chart 1**.

### Specific Diagnosis

This is possible through the combination of blood acylcarnitine by tandem mass spectrometry (TMS) or plasma amino acid profile and urine organic acid profile by GCMS. GCMS is helpful in identifying the unmeasured organic anions,  $\beta$ -hydroxybutyrate and acetoacetic acid. While ordering these special tests, it is mandatory to include full details about the diet, fluids and drugs provided to the patient. Sample should be rapidly transported to the laboratory. In case blood transfusion is anticipated, a pretransfusion sample should be obtained.

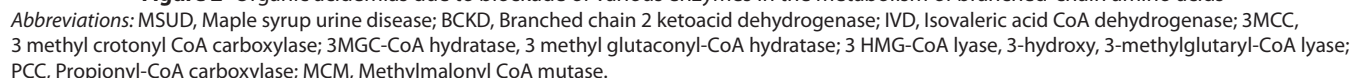

Specific enzyme assay or DNA testing provides further confirmation. These studies are basically helpful for the prenatal diagnosis in future pregnancies.

## MANAGEMENT

Management of a child presenting with organic acidemia is done in two phases: (i) initial acute management, (ii) ongoing long-term management.

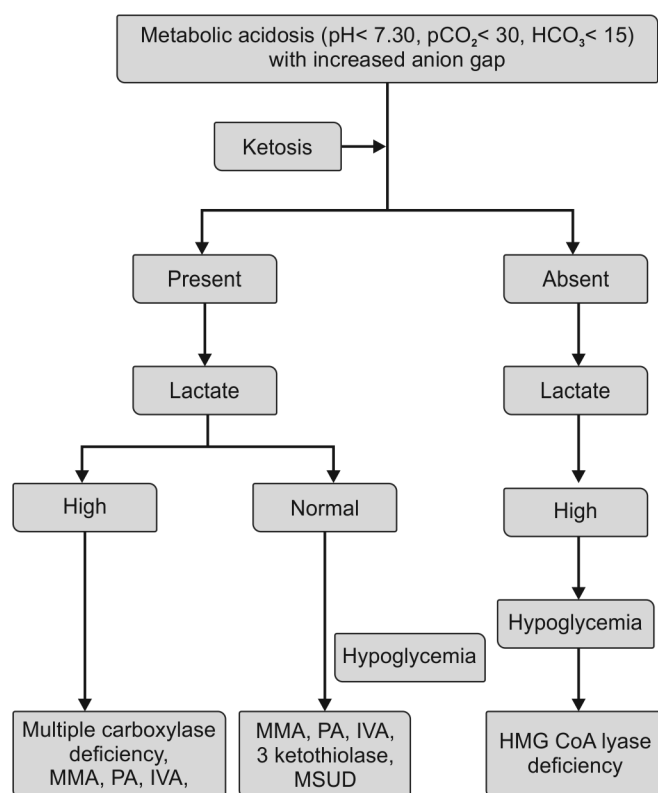

**Figure 1** Factors responsible for organic acid origin

**Abbreviations:** MMA, methylmalonic acidemia; PA, propionic acidemia; IVA; isovaleric acidemia; GA-1, glutaric acidemia type 1; MSUD, maple syrup urine disease.

Any child with acute presentation should be first stabilized and assessed for any circulatory and ventilatory support. Majority of these patients require maintenance of hydration, and correction of metabolic acidosis, hypoglycemia, dyselectrolytemia and hypocalcemia as guided by the initial screening investigations. Such patients frequently suffer from infections that can result in persistent catabolism and therapeutic failure. Major steps of initial management include maintenance of intravenous line and collection of various samples (**Table 2**). Hydration and anabolic state is maintained using 5–10% intravenous dextrose in 0.2% of NaCl at 1.25–1.5 times calculated maintenance. KCl is added once the adequate urinary output is established. The caloric intake of up to 100–120 kcal/kg/day can be given. Protein is eliminated from diet. Some experts recommend use of insulin to promote anabolic state. Within 1–2 days of initial management, low protein diet is introduced gradually over a period of 2–3 days to prevent catabolic state due to acute protein malnutrition and to promote adequate growth. Patients with severe metabolic acidosis and hyperammonemia usually require hemodialysis which is more efficient than peritoneal dialysis. Carnitine therapy is given to compensate for secondary carnitine deficiency which is often seen in such patients due to urinary excretion of carnitine-bound organic acids. *Supportive care* includes artificial ventilation for respiratory insufficiency, treatment of raised intracranial tension and cerebral edema, antibiotics for associated infections and anticonvulsants for seizures.

**Flow chart 1** Outline for the approach to different organic acidemia**Table 2** Basic metabolic investigations in an acutely sick baby

Test (normal range)	Remarks
Serum ammonia	
• Neonates	• Rapidly flowing fasting blood (uncuffed venous or arterial)
– Healthy: < 110 $\mu\text{mol/L}$	• Sample is transported on ice
– Sick: up to 180 $\mu\text{mol/L}$	• The test should be done within 1 hour, so prior notification to the laboratory is desirable
– Suspect IEM: > 200 $\mu\text{mol/L}$	• Artefactual elevations are common
• After the neonatal period	
– Normal: 50–80 $\mu\text{mol/L}$	
– Suspect IEM: > 100 $\mu\text{mol/L}$	
Lactate	
• Blood: < 2.4 mmol/L	• Should be sent immediately to the lab for analysis
• CSF: < 2.0 mmol/L	• Artefactual elevations are common
Blood gas for pH and anion gap (normal anion gap = 15–20 mmol/L)	Increased in organic acidemia
Blood glucose	
Urinary ketones	
Others	
• Blood count, liver function test, renal function test	

Abbreviations: IEM, Inborn errors of metabolism; CSF, cerebrospinal fluid.

### Long-term Treatment

Long-term management includes maintenance of adequate metabolic control with periodic biochemical monitoring. A metabolic dietician has a vital role in providing age-specific adequately protein-restricted diets. Calcium supplements and specific vitamin therapy are given depending upon the type of specific defect.

## SPECIFIC DISORDERS

### Maple Syrup Urine Disease

Maple syrup urine disease is classified both as organic acidemia and aminoacidopathy. It is caused by the deficiency of the branched-chain  $\alpha$ -keto acid dehydrogenase complex, a common enzyme involved in the second enzymatic step in the degradative pathway of the BCAAs—leucine, isoleucine and valine.

#### Genetics

Maple syrup urine disease is a rare autosomal recessive metabolic disorder with an incidence of approximately 1:200,000 livebirths. Three genes are responsible for MSUD—(i) *BCKDHA*, encoding branched-chain keto acid (BCKA) decarboxylase (E1)  $\alpha$ -subunit (MSUD type 1A); (ii) *BCKDHB*, encoding BCKA decarboxylase (E1)  $\beta$ -subunit (MSUD type 1B); and (iii) *DBT*, encoding dihydrolipoyl transacylase (E2) subunit (MSUD type 2).

#### Clinical Features

The clinical phenotype depends upon the residual enzyme activity with classical and severe phenotype being associated with deficient activity (< 2%) and milder or intermittent phenotypes with partial enzyme activity (3–40%). Classically such patients have neonatal presentation mostly after 3–5 days of life and present with poor feeding, irritability followed by progressive encephalopathy with lethargy, respiratory abnormalities, opisthotonus, stereotypic limb movements, such as *fencing and bicycling* and finally coma and central respiratory failure. Milder forms present with poor feeding and growth along with developmental delay. They may have encephalopathy like episodes during illness. Intermittent forms have mild to severe episodic illness precipitated by any catabolic state. The severity of the neurological involvement and encephalopathy is directly related to the leucine concentration and requires careful monitoring.

#### Diagnosis

Most babies present with typical clinical features and ketonuria is often precipitated by a catabolic event. Hypoglycemia and mild hyperammonemia may be seen uncommonly in such patients.

Diagnosis is made by detection of BCKAs and  $\alpha$ -hydroxyl acids in urine by following biochemical methods:

- **Dinitrophenylhydrazine (DNPH) test** Equal volumes of urine and DNPH reagent are mixed and color change is observed after 10 minutes. A positive test is indicated by the presence of yellow-white precipitate. It is a good bedside test.
- GCMS for BCKAs and hydroxyacids.
- Plasma amino acids show elevated levels of all BCAAs especially leucine.
- Enzyme activity measurement in different cells.
- DNA testing for three genes: (i) *BCKDHA*; (ii) *BCKDHB*; and (iii) *DBT*.

#### Treatment

Acute phase management for metabolic decompensation includes lowering down the toxic concentration of leucine and reversal of acute metabolic decompensation by exogenous removal of toxins with either hemodialysis or hemofiltration. This rapidly lowers the levels of leucine. Levels of valine, isoleucine also fall below the normal level. To stimulate the adequate protein synthesis, such patients require oral BCAAs free formula along with adequate calories and supplementation with isoleucine and valine during recovery. A careful monitoring of plasma BCAA, especially leucine is needed to ensure adequate metabolic control.

Long-term management requires strict and carefully monitored diet and includes combination of measured proportion of natural

protein (BCAA containing food) and BCAA-free special diet. The goal is to achieve postprandial plasma concentration of leucine (80–200  $\mu\text{mol/L}$ ), isoleucine (40–90  $\mu\text{mol/L}$ ) and valine (200–425  $\mu\text{mol/L}$ ), normal or near normal values. The dietary adjustment is usually based upon plasma leucine concentration (being most toxic) to maintain a plasma leucine-to-valine concentration ratio (mol:mol) of half (0.5) or less and a leucine-to-isoleucine ratio of about 2.0. This requires judicious supplementation with isoleucine and valine. Unlike other organic acidemias, carnitine supplementation is not required as no abnormal acylcarnitine is formed. Supplementation with thiamine (50–100 mg twice a day) may be helpful in thiamine responsive forms. Liver transplantation results in increased enzymatic activity, avoidance of BCAA-free special diet and metabolic decompensation during catabolic states.

### Propionic Acidemia and Methylmalonic Acidemia

Propionic and methylmalonic acids are formed from the catabolism of BCAAs, like isoleucine and valine, odd-chain fatty acids and cholesterol. They are ultimately converted to succinyl CoA which feeds into the Krebs cycle. Defects in any of the steps below result in the accumulation of toxic precursors.

#### Genetics

Propionic acidemia (PA) and methylmalonic acidemia (MMA) are autosomal recessive disorders. PA results from mutations in propionyl CoA carboxylase alpha (PCCA) or propionyl CoA carboxylase beta (PCCB) gene encoding  $\alpha$  and  $\beta$  units of propionyl CoA carboxylase (PCC) enzyme. Incidence of PA is less than 1 in 100,000.

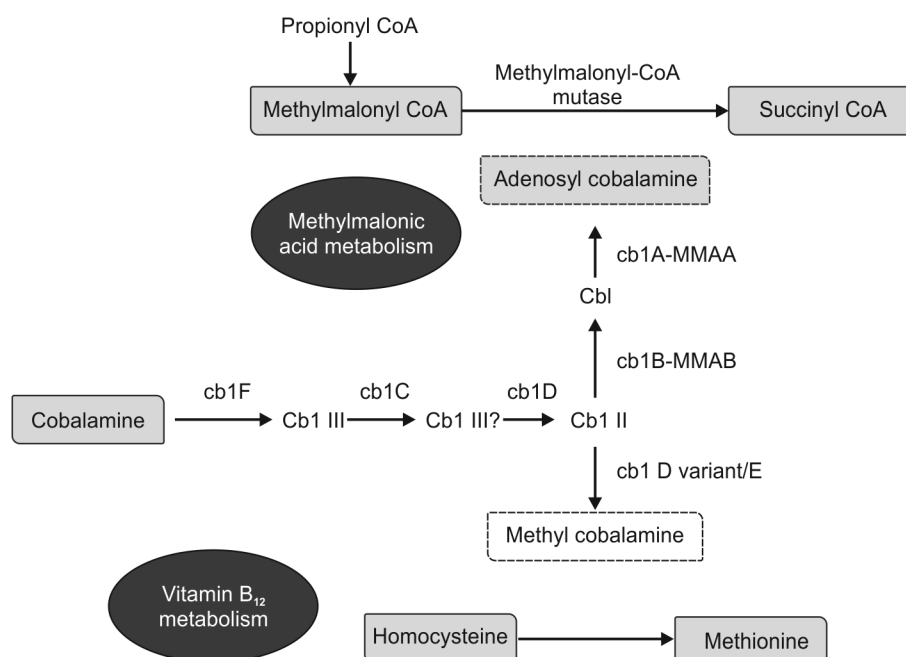

Methylmalonic acidemia is caused either by mutations in *MUT* gene encoding methylmalonyl-CoA mutase (MCM) enzyme or by genetic defects in the genes required for its cofactor. In approximately 50–65%, mutations in *MUT* gene cause MMA, the remaining patients have various cobalamin variants. MMA is relatively more common than PA with an incidence of 1 in 50,000.

### Pathophysiology

As shown in the **Figure 2**, PA is caused by a deficiency of the mitochondrial enzyme PCC, a biotin-dependent enzyme. In the absence of PCC activity, intermediary products such as propionylcarnitine, 3OH-propionate and methylcitrate accumulate.

Methylmalonic acidemia occurs either due to the deficiency of adenosylcobalamin-dependent MCM or due to deficiency of enzymes interfering with the transport and metabolism of its cofactor, adenosylcobalamin. Deficiency in either of these two enzymes results in greatly increased levels of methylmalonic acid in plasma and urine. As propionyl CoA carboxylation is reversible, propionate metabolites also accumulate and can be seen in plasma or urine of patients with MMA. Depending upon the level of enzyme activity, whether completely or partially absent, these are classified as *mut*<sup>0</sup> or *mut*<sup>-</sup>. Defect in MCM cofactor adenosylcobalamin synthesized from vitamin B<sub>12</sub> can occur due to mitochondrial cobalamin reductase deficiency (*cb1A*) and mitochondrial cobalamin adenosyltransferase deficiency (*cb1B*). Both MMA and homocystinuria can occur due to defects in adenosyl and methylcobalamin synthesis and are classified as cobalamin *cb1C*, *cb1D* and *cb1F*. In all these disorders, the levels of plasma vitamin B<sub>12</sub> are normal. The other cause of increased urine and plasma methylmalonic acid is vitamin B<sub>12</sub> deficiency secondary to dietary deficiency and seen exclusively in breastfed infants of vegan mothers. In vitamin B<sub>12</sub> deficiency, the deficient plasma levels of vitamin B<sub>12</sub> are seen in combination with MMA.

**Figure 3** depicts the linkage between various intracellular metabolic pathways involving vitamin B<sub>12</sub>, homocysteine, catabolism of isoleucine and Krebs cycle. Based upon the plasma concentration of MMA, homocysteine and vitamin B<sub>12</sub> levels, the type of defect can be characterized. Accumulation of secondary metabolites in both PA and MMA leads to inhibitory effect on various pathways causing hypoglycemia, elevated plasma lactate, hyperammonemia and hyperglycinemia.

**Figure 3** Close linkage between vitamin B<sub>12</sub> and methylmalonic acid metabolism

## Clinical Features

Most babies with severe forms of PA and MMA have similar clinical presentations and present with metabolic acidosis, ketosis, hypoglycemia, vomiting, hypotonia and lethargy during neonatal period. During late infancy, they present with failure to thrive, intermittent decompensation associated with illness or fasting, Reye syndrome like illness, seizures, and metabolic derangements like hypoglycemia. Milder forms can have developmental delay, chronic progressive neurological disease, ataxia, metabolic stroke, extrapyramidal signs. About 25–50% of patients with PA have dilated or hypertrophic cardiomyopathy and can also have conduction abnormalities. Patients with PA or MMA may have subtle facial dysmorphism like triangular mouth, broad nasal bridge, epicanthic folds and smooth philtrum.

## Diagnostic Tests

### Propionic acidemia

- Urine organic acid analysis by GCMS shows presence of 3OH-propionate, methylcitrate, propionylglycine and tiglyglycine.
- Blood acylcarnitine analysis shows increased propionylcarnitine (C3), low free carnitine due to secondary carnitine deficiency.
- Enzyme assay of 14C-propionate incorporation into cultured fibroblasts or PCC in cultured fibroblasts or leukocytes confirms the diagnosis.
- DNA analysis for PCCA and PCCB gene analysis.

### Methylmalonic acidemia

- Urine organic acid analysis shows presence of methylmalonate, 3OH-propionate and methylcitrate.
- Blood acylcarnitine analysis shows raised propionylcarnitine (C3) but low free carnitine levels as seen in PA.
- Complementation analysis, though not routinely available in India, is helpful in determining the affected gene.
- DNA analysis for various genetic defects can be done. Prenatal diagnosis is possible by analyzing the previously identified genetic defect in the fetus. In case mutation is not known, direct measurement of metabolites in amniotic fluid can also be performed.

## Treatment

**Acute management** Stop protein intake. Promote anabolism by providing glucose and insulin. Correct metabolic acidosis. Administer sodium benzoate to remove ammonia and/or L carnitine to remove propionic acid.

**Long-term treatment** Goal is to reduce the levels of toxic intermediary metabolites, i.e., methylmalonic acid and propionic acid. This can be achieved by natural protein restriction (1–1.5 g/kg/day) that provides at least minimum amount of protein and essential amino acids to ensure normal growth. The diet has to be individualized depending upon the patient's nutritional status, metabolic control and age. One should avoid fasting and restrict protein during intercurrent illness that promotes catabolism. In cases of isolated MMA, provide diet restricted in BCAAs, odd-chain fatty acids and polyunsaturated fatty acids. Patients with combined MMA and homocystinuria require a diet restricted both in BCAA and methionine and threonine. Biochemical monitoring to ascertain MMA levels is frequently required.

### Drugs

- L-Carnitine (100 mg/kg/day)
- Metronidazole for reduction of intestinal production of propionic acid. It is given at 10–20 mg/kg/day orally as a single dose for 10 consecutive days every month.
- Betaine may also be given in the presence of homocystinuria. It acts as a methyl donor and reduces the homocysteine concentration converting homocysteine to methionine. It is given at 100 mg/kg/day orally, divided into two doses given every 12 hours.

- **Injection hydroxycobalamin** Patients with partial defects in adenosylcobalamin synthesis sometimes respond to supraphysiological doses of injection hydroxycobalamin 1,000–2,000 µg/day for about 5–10 days. Repeat urine organic acid analysis shows decrease in the intermediary metabolites confirming the responsiveness to vitamin B<sub>12</sub>. Most vitamin B<sub>12</sub> responsive patients require mild protein restriction with either daily oral vitamin B<sub>12</sub> or weekly 1,000–2,000 µg parenteral and folate supplements (15 µg/kg).

## Prognosis

Patients who are vitamin B<sub>12</sub> responsive MMA have milder disease and relatively good prognosis. Otherwise overall prognosis of MMA and PA is poor. Most of the patients with acute presentation either die during neonatal period or during any episode of decompensation. Despite good metabolic control, survivors develop developmental delay, metabolic strokes and learning difficulties. Toxic effects of MMA cause renal tubular acidosis and tubule interstitial nephritis. Renal disease and optic atrophy are late complications of MMA.

Despite treatment, patients with PA develop developmental delay, neurocognitive decline, seizures, movement disorders, osteoporosis, cardiomyopathy and pancreatitis. Recurrent pancreatitis is a common complication. Liver or combined liver-renal transplantation may be an option in certain patients with severe and recurrent metabolic decompensation. It averts the metabolic decompensation and can reverse the cardiomyopathy in PA.

## Glutaric Acidemia Type 1

Glutaric aciduria type 1 is probably the second common organic acidemia in India, the most common being MMA. The estimated worldwide frequency of GA 1 varies from 1 in 30,000 to 1 in 100,000 newborns in different population.

## Genetics

Glutaric acidemia type 1 or glutaric aciduria type 1 occurs due to the deficiency of glutaryl-CoA dehydrogenase (GCDH) enzyme, a member of the acyl-CoA dehydrogenase family and a key enzyme in the catabolic pathways of the amino acids—tryptophan, lysine and hydroxylysine. Deficiency of GCDH causes increased urinary organic acid excretion of glutaric acid, 3-hydroxyglutaric acid, glutaconic acid and elevated glutaryl carnitine (C5) in plasma.

## Clinical Features

These children have a variable course of illness, majority of patients presenting with neuroregression precipitated by an acute febrile illness, macrocephaly and extrapyramidal symptoms (**Fig. 4**). About 90% of the affected children present classically between 2 months and 37 months of age with extrapyramidal symptoms, predominantly dystonia superimposed on axial hypotonia after an acute encephalopathic crisis precipitated by intercurrent febrile illness, infection, fasting or immunization. About 75% of the patients have macrocephaly with soft neurological signs, such as head lag, irritability and feeding difficulties. Extrapyramidal symptoms are due to bilateral striatal injury during the acute episode.

## Diagnosis

There may be fluctuating and inconsistent metabolic abnormalities. In acute episodes, there may be hypoglycemia, metabolic acidosis and hyperammonemia.

- TMS shows elevated glutaryl carnitine and/or low free carnitine levels.
- Urine organic acids show variable degree of elevation of glutaric acid and 3-hydroxyglutarate (**Fig. 5**).

**Figure 4** Three frequently observed features in patients with glutaric acidemia type 1

**Figure 5** Urinary organic acid profile in a patient with glutaric aciduria type 1

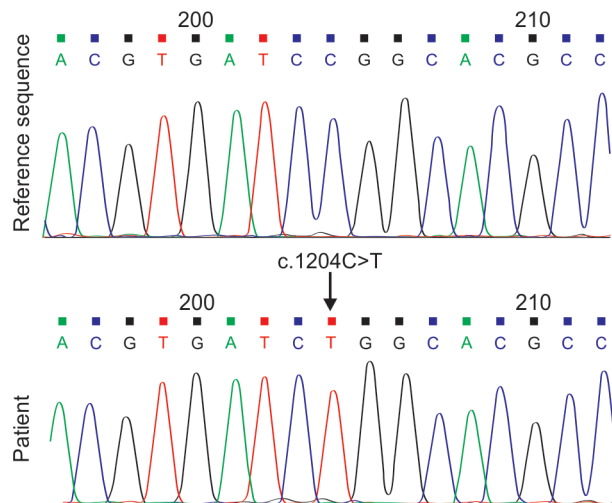

- Neuroimaging shows presence of both striatal (hyperintensities in basal ganglia) and extrastriatal (subdural hygroma, wide sylvian fissure, frontotemporal atrophy) abnormalities.
- Enzyme analysis or mutation analysis of GCDH gene provides a definitive diagnosis. **Figure 6** shows the presence of a common mutation c.1204C>T(p.Arg402Trp) in one of the patients.

### Management

Management of acute episodes for restoring the normal acid base and electrolyte balance is followed as per standard management.

**Long-term management** The aim of dietary treatment is to reduce the accumulation of the presumed toxic agent glutaric acid by reducing its rate of formation. Patients are kept on lysine and tryptophan restricted low protein diet along with riboflavin (100–300 mg/day). Baclofen is given for dystonia. Patients are also given carnitine supplementation (100 mg/kg/day) to avoid carnitine depletion secondary to the excretion of glutaryl carnitine.

As early diagnosis and prompt initiation of treatment can prevent the long-term complications and mortality, it is one of the potential disorders that can be included in newborn screening program.

**Figure 6** A homozygous mutation c.1204 C>T (p.Arg402Trp) in exon 11

### IN A NUTSHELL

1. Organic acidemias are a group of disorders characterized by increased urinary excretion of organic acids.
2. These usually present around 7–10 days after birth with sepsis like illness, metabolic acidosis and increased anion gap. Glutaric acidemia is an exception that usually presents during late infancy.
3. The basic metabolic screen includes measurement of blood glucose, electrolytes, acid-base status for metabolic acidosis, blood lactate levels, ammonia levels and urinary ketones.
4. Characterization of a particular organic acidemia needs measurement of urine organic acids and TMS. Definitive diagnosis is possible by specific enzyme estimation or DNA analysis for the defective genes.
5. Initial management of any child with acute presentation involves elimination of dietary protein, maintenance of hydration and correction of various metabolic and electrolyte imbalance. Patient should not be kept protein deprived for a long time after initial stabilization and is started on protein-restricted diet (excluding the offending amino acids) gradually.
6. Drugs such as sodium benzoate and/or carnitine may be given to reduce the formation or increase the excretion of toxic metabolites.
7. All organic acidemias are autosomal recessive in nature and hence carry a recurrence risk of one in four in future pregnancies.

## Chapter 3.5

# Fatty Acid Oxidation Defects

Manisha Goyal, Seema Kapoor

Fatty acids are largest source of energy in the body and play an essential role for exercising muscles and heart. It is clear from **Figure 1** that preferential utilization substrate for the brain is glucose followed by ketones. When glucose diminishes (during fasting) and the rehabilitative metabolic systems fail, ketones may not increase and the hypoglycemia is hypoketotic. In such an event, brain relies on the fatty acid oxidation (FAO) system for providing energy.

## LENGTH OF FATTY ACIDS AND THEIR NOMENCLATURE

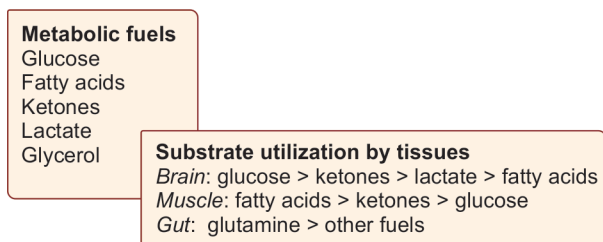

*Short-chain fatty acids* have carbon atoms which are less than 6 carbon atoms while *medium chain* varies from 6–12 carbon atoms, *long chain* between 14 and 21 carbon atoms and *very long chain* more than 21 fatty acids. The term saturated and unsaturated is the presence of double bonds between carbon atoms. Those unsaturated fatty acids with single double bond are monounsaturated and those with no double bonds are polyunsaturated fatty acids. Long-chain fatty acids (LCFAs) play a role in phospholipid synthesis, protein post-translational modifications, cell signaling, membrane permeability and transcription control. LCFA are also substrates in the situations of increased energy demands.

## FATTY ACID OXIDATION PATHWAY

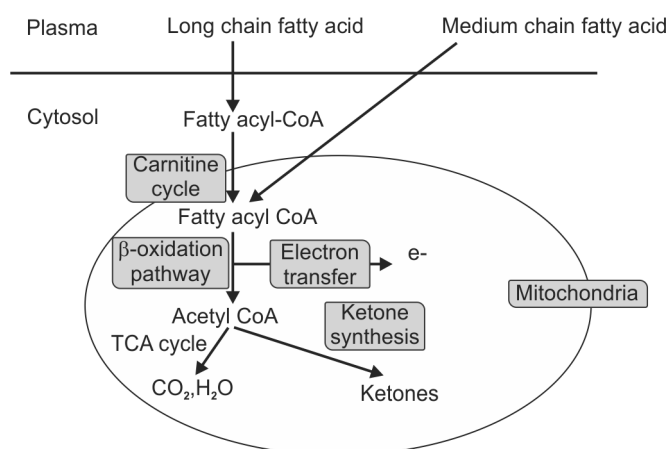

Fatty acid oxidation process takes place in the mitochondrion and plays an important role during periods of fasting and stress when glycogen stores of the tissue become depleted. FAO process becomes a major source of energy (nearly 80%) to organs like skeletal muscles, heart and liver especially during fasting. Fatty acids are completely utilized and converted to carbon dioxide and water in the skeletal muscles and heart. In the liver, ketone bodies (acetoacetate and  $\beta$ -hydroxybutyrate) are produced which are the substrate used by peripheral tissues and brain. Disorders of this pathway would result in fatty acid oxidation defects (FAOD) with symptoms including hepatic encephalopathy, myopathy, cardiomyopathy and peripheral neuropathy. Other conditions suggesting FAOD are sudden infant death syndrome (SIDS), Reye syndrome and maternal complications of pregnancy caused by fetal FAOD.

**Figure 2** represents a schematic diagrams of the mitochondrial FAO pathway from cellular uptake of fatty acids to generate acetyl-CoA in the  $\beta$ -oxidation spiral, its association with respiratory chain and ketogenesis. The short- and medium-chain fatty acids can diffuse directly across the plasma and mitochondrial membranes into the mitochondrial matrix. In contrast, LCFAs ( $C_{14}$ – $C_{21}$ ) and carnitine are transported by specific plasma membrane transporters. Fatty acids are converted to their respective acyl CoA esters by individual acyl CoA synthetases. Short-chain and medium-chain fatty acids are activated within the mitochondrial matrix, whereas LCFAs are esterified outside the mitochondria and then enter into the mitochondrial matrix.

In the carnitine cycle (**Fig. 3**), LCFAs are transported across the mitochondrial membrane involving the enzymes carnitine-I, carnitine palmitoyltransferase-II and carnitine acylcarnitine translocase with carnitine as a cofactor. Within the mitochondria, the fatty acyl CoA esters undergo repeat cycles of reactions catalyzed

**Figure 1** Metabolic fuels and their priority of utilization

**Figure 2** Fatty acid oxidation pathway

**Figure 3** Carnitine cycle

by enzymes and convert into acetyl CoA units through  $\beta$ -oxidation cycle (**Fig. 4**). The electrons generated in the  $\beta$ -oxidation step enter into the electron transfer pathway for ATP production and in the respiratory chain. Acetyl CoA generated in liver is transformed to ketone bodies ( $\beta$ -hydroxybutyrate and acetoacetate) through ketogenesis pathway (**Fig. 5**).

## FATTY ACID OXIDATION DEFECTS

Fatty acid oxidation defects are inherited as autosomal recessive disorders. Mutations have been identified for most of the disorders. Incidences of individual FAOD may vary from 1:8000 to 1:100,000. The clinical and biochemical features of major FAOD are

**Figure 4**  $\beta$ -Oxidation cycle

**Figure 5** Ketone synthesis

**Abbreviations:** CoA, coenzyme A; CPT, carnitine palmitoyltransferase; FAD, flavin adenine dinucleotide; FADH, reduced FAD; HMG-3, hydroxy-3-methylglutaryl; TCA, tricarboxylic acid; TFP, trifunctional protein; TRANS, carnitine/acylcarnitine translocase; NAD, nicotinamide adenine dinucleotide; NADH, reduced NAD; vLCAD, very long-chain acyl-CoA dehydrogenase; LCAD, long-chain acyl CoA dehydrogenase; MCAD, medium-chain acyl CoA dehydrogenase; SCAD, short-chain acyl CoA dehydrogenase; SCHAD, short-chain 3-hydroxyacyl-CoA dehydrogenase.

summarized in **Table 1**. FAODs become apparent during periods of increased energy demands, such as prolonged fasting, febrile illness or any other stressful situation during which the inability to use fatty acids causes metabolic decompensation. There are overlapping phenotypes between the various enzyme defects of FAO and the same defective enzyme may be associated with considerable clinical heterogeneity.

## CLINICAL PHENOTYPE

Affected patients may be asymptomatic or may show wide variety of symptoms, such as severe metabolic acidosis, hypoglycemia without ketosis, hyperammonemia, cardiomyopathy, liver failure, sudden death in the neonatal period, episodic myopathy, neuropathy or retinopathy in the later age. It can broadly be categorized into neonatal hypoketotic hypoglycemia, childhood hepatic form, adult onset myopathic form or the form with retinopathy. Clinical features become more apparent during periods of increased energy demands

such as prolonged fasting, febrile illness. This is an important clinical clue for ascertaining the diagnosis. The phenotype is severest with long-chain defects, milder with medium chain and none to minimal in short-chain defects.

## Association of Sudden and Unexpected Death with FAOD

Sudden death after a relatively short prodromal illness is the first manifestation of medium-chain acyl CoA dehydrogenase (MCAD) deficiency in 18% of patients and is also reported in adulthood. A protocol for postmortem investigation for FAOD is thus suggested for all cases of unexplained death to detect present and future siblings in the family of patients with SIDS.

## Association of Fetal FAOD with Severe Complications during Pregnancy

The association of severe complications such as preeclampsia, HELLP syndrome (hemolysis, elevated liver enzymes and low platelet counts), AFLP (acute fatty liver of pregnancy) with women carrying long-chain L3-hydroxyacyl CoA dehydrogenase (LCHAD) deficient fetus has been well documented. While the causes of maternal pregnancy complications with fetal FAOD are not clear, these cases suggest that derangement of mitochondrial fatty acid metabolism may play a role in the pathogenesis of maternal liver disease. Investigation for FAOD should be considered in all babies born of a pregnancy complicated by HELLP syndrome or AFLP.

## Association of Fatty Acid Oxidation Disorders with Endocrinopathy (Hormonal Imbalance)

Hypoparathyroidism has been detected in patients with LCHAD deficiency. One patient with hypopituitarism and the other with secondary hypothyroidism have been reported with short-chain acyl CoA dehydrogenase (SCAD) deficiency. Intermittent and unpredictable hyperinsulinism in an infant with short-chain L3-hydroxyacyl CoA dehydrogenase (SCHAD) deficiency has also been documented.

## DIAGNOSTIC TESTS

The biochemical manifestations of FAOD include accumulation of free fatty acids (FFAs) and toxic acyl CoA intermediates and deficient production of acetyl CoA and ketone bodies.

### Plasma Acylcarnitines

Fatty acid oxidation defects can be diagnosed by analyses of acylcarnitines on dried blood spot (DBS) on filter paper followed by confirmation on plasma. Most of the FAOD may be differentiated by levels of disease-associated acylcarnitine types. Some medications such as valproic acid, pivalic acid or propofol can produce increased concentrations of abnormal acylcarnitine.

### Plasma and Tissue Total Carnitine

Fatty acid oxidation defects are associated with either decreased or increased total carnitine in plasma and tissues. In carnitine transport defects, transport of carnitine across the plasma membrane is absent, leads to severe reduction of total carnitine (primary carnitine deficiency). Total carnitine levels are increased in carnitine palmitoyltransferase-I (CPT-I) deficiency. Total carnitine levels are reduced to 25–50% of normal in all other defects, except 3-hydroxy-3-methylglutaryl (HMG) CoA synthase deficiency known as secondary carnitine deficiency. It is recommended that samples should be taken in the well-fed state with normal carnitine intake because patients during prolonged fasting or illness may show abnormal increases in the plasma total carnitine with FAOD, thereby missing the diagnosis.

**Table 1** Fatty acid oxidation defects

Defects	Gene	Clinical features	Dried blood spot (carnitine and acylcarnitine)	Urine organic acid profile or acylglycine
<i>Plasma membrane cellular uptake and activation of long-chain fatty acids</i>				
Plasma membrane carnitine transporter (primary carnitine deficiency)	OCTN2	Liver disease, heart disease (cardiomyopathy, endocardial fibroelastosis), myopathy, sudden death	Total and free carnitine: ↓, acylcarnitines: N	N
Long-chain fatty acid transporter protein	FATP1–6	Rare, acute liver failure	Free carnitine: N/↑, acylcarnitine: N	N
<i>Defects in the carnitine cycle</i>				
Carnitine palmitoyltransferase-I (CPT-IA) deficiency	CPT-IA	Liver failure, tubulopathy of kidney, maternal preeclampsia or HELLP syndrome	Free carnitine: N/↑, acylcarnitine: N	N
Carnitine acylcarnitine translocase (CACT) deficiency	CACT	Hypertrophic cardiomyopathy, chronic progressive liver failure	Free carnitine: N/↓, acylcarnitine: abnormal	-/N
Carnitine palmitoyltransferase-II (CPT-II) deficiency	CPT-II	Liver disease, cardiomyopathy, skeletal myopathy, encephalopathy, renal cystic changes	Free carnitine: N/↓; acylcarnitine: ↑ C <sub>16</sub> , C <sub>16:1</sub> , C <sub>18</sub> , C <sub>18:1</sub>	-/N
<i>Defects in the β-oxidation cycle</i>				
Short-chain acyl CoA dehydrogenase (SCAD) deficiency	SCAD	Variable presentation, vary from normal to inconsistent sign and symptoms	Free carnitine: N/↓; acylcarnitine: abnormal C <sub>14:1</sub> , C <sub>14:0</sub>	Elevated urine ethylmalonic acid, butyryl acylglycines
Medium-chain acyl CoA dehydrogenase (MCAD) deficiency	MCAD	Sudden death, hypoglycemia, hepatic encephalopathy, maternal preeclampsia or HELLP syndrome	Free carnitine: N/↓, plasma acylglycine: ↑, plasma C <sub>6</sub> -C <sub>10</sub> Free fatty acids: ↑, C <sub>8</sub> -C <sub>10</sub> acylcarnitine: ↑	Elevated suberyl and phenylpropionyl acylglycines
Very long chain acyl CoA dehydrogenase (VLCAD) deficiency	VLCAD	Heart (dilated cardiomyopathy, arrhythmias), hypoglycemia, hepatic steatosis, episodic myopathy, rhabdomyolysis	Free carnitine: N/↓; C <sub>14:1</sub> , C <sub>14</sub> acylcarnitine: ↑; plasma C <sub>10</sub> -C <sub>16</sub> free fatty acids: ↑	+/-/N
Short-chain L-3-hydroxyacyl CoA dehydrogenase (SCHAD) deficiency	SCHAD	Hypoglycemia, cardiomyopathy, myopathy, hyperinsulinemia	Free carnitine: N/↓, free fatty acids: elevated, acylcarnitine: abnormal	Abnormal
Long-chain L-3-hydroxyacyl CoA dehydrogenase (LCHAD) deficiency	LCHAD	Maternal complications: Pre-eclampsia, HELLP syndrome, AFLP	Free carnitine: N/↓, acyl to free carnitine ratio: ↑, free fatty acids: ↑, C <sub>16</sub> -OH and C <sub>18</sub> -OH carnitines: ↑	+/-/N
Mitochondrial trifunctional protein (TFP) deficiency	MTP	Deranged LFT, hypoglycemia, myopathy, retinopathy	Free carnitine: N/↓, acyl to free carnitine ratio: ↑, free fatty acids: ↑, C <sub>16</sub> -OH and C <sub>18</sub> -OH carnitines: ↑	+/-/N
<i>Defects in electron transfer pathway</i>				
Electron transfer flavoprotein dehydrogenase deficiency/Glutaric aciduria type II or multiple acyl CoA dehydrogenase deficiency (MADD)	ETF-DH	Liver disease, nonketotic fasting, hypoglycemia, congenital anomalies, myopathy (cardiac and skeletal)	Free carnitine: N/↓, acyl to free carnitine ratio: ↑, acylcarnitine: ↑	↑ acylglycines (isovaleryl and hexanoyl) Elevated ethylmalonic organic acid
Electron transfer flavoprotein-α and β	α/β-ETF	Liver disease, hypoglycemia, congenital anomalies, myopathy (cardiac and skeletal)	Free carnitine: N/↓, acyl to free carnitine ratio: ↑, acyl-carnitine: ↑	↑ acylglycines
Long-chain 3-ketoacyl-CoA thiolase deficiency	LKAT	Hypoglycemia, cardiomyopathy, neuropathy, acidosis, ↑ CPK, sudden death	Free carnitine: N/↓, acyl to free carnitine ratio: ↑, acylcarnitine: ↑, 2-trans, 4-cis-decadienoylcarnitine: ↑	+/-/N
2,4-dienoyl-CoA reductase deficiency	DECR1	Hypotonia, myopathy, respiratory failure	Free carnitine: N/↓, acyl to free carnitine ratio: ↑, acylcarnitine: ↑	↑ acylglycines

Contd...

Contd...

Defects	Gene	Clinical features	Dried blood spot (carnitine and acylcarnitine)	Urine organic acid profile or acylglycine
<i>Defects in the ketone synthesis pathway</i>				
3-hydroxy-3-methylglutaryl CoA (HMG CoA) synthetase deficiency	HMGCS2	Hypoglycemia, hypoketosis	Total free fatty acids: ↑	
3-hydroxy-3-methylglutaryl CoA (HMG CoA) lyase deficiency	HMGCL	Hypoglycemia, hypoketosis	Free carnitine: N, C <sub>5</sub> -OH and methylglutaryl-carnitine: ↑	↑ 3-hydroxy-3-methyl glutaric acid

Abbreviations: N, normal; CPK, creatine kinase; HELLP, hemolysis, elevated liver enzymes, low platelets; AFLP, acute fatty liver of pregnancy.

### Urinary Organic Acids

Compounds produced by urinary analyses of organic acids are indicator of FAOD which include the saturated and unsaturated dicarboxylic acids, hydroxydicarboxylic acids, acylglycines and acylcarnitines. All of the disorders are associated with an inappropriate dicarboxylic aciduria during fasting or illness without ketonuria. It is usually normal in patients with FAOD when they are well. Thus, in the intermittent phase, the urinary metabolomic profile would be completely normal and, therefore, misleading.

### Urinary Acylglycines

Quantitative analysis of urinary acylglycines is diagnostic in MCAD and the severe form of multiple acyl CoA dehydrogenase (MAD) deficiency.

### Plasma Fatty Acids

Analysis of plasma total fatty acid (TFA) and FFA profiles can detect MCAD deficiency. Increased levels of free 3-hydroxyl fatty acids are found in LCHAD, SCHAD and MTP (mitochondrial trifunctional protein) deficiencies. Deficiencies of SCAD, CPT-1A, CPT-II and CT may not be identified as these defects did not show any specific alteration of the FFA profiles.

### Enzyme Assays

Measuring enzyme activity is necessary for confirmation of the diagnosis. Enzyme assays defective in the FAO pathway may be performed in cultured skin fibroblasts, tissue biopsies or lymphocytes.

### Molecular Studies

Mutation analysis can be performed on peripheral blood leukocytes, or obviating the need for cell culture or biopsies. This study provides specific confirmation; establish genotype-phenotype relationships in some disorders which have implications for prognosis and options of treatment and essential for prenatal diagnosis.

## TREATMENT

### Reduce Production of Circulating Free Fatty Acids

The mainstay of treatment is to modify diet to prevent fasting state in which fatty acids are used to produce energy. For long-chain fat disorders, dietary modifications include maintaining a very low intake of natural fats with supplementary medium-chain triglycerides (MCTs), high carbohydrate and adequate essential fatty acids. It is recommended that feeding should be done at regular intervals during day and night and can be given in the continuous nasogastric mode overnight. In states of significant anorexia, a gastrostomy may need to be performed.

### Increase Residual Enzyme Activity

Riboflavin is known to improve enzyme activity in MAD deficiency. It has been used for mild variants of electron transfer flavoprotein/electron transfer flavoprotein dehydrogenase (ETF/ETF-DH) and SCAD deficiency. Dose is 100 mg/kg. Benzaifibrate (agonist to peroxisome proliferator-activated receptors) plays an important role by up-regulating gene expression in lipid metabolism and  $\beta$ -oxidation pathway. It is used for very long chain acyl CoA dehydrogenase (VLCAD) and CPT-II deficiency.

### Replace the Missing Product

Since ketone production is defective in FAOD, it would be helpful to supply the missing ketones. Sodium 3-hydroxybutyrate has been found to be effective in MAD deficiency.

### Carnitine Therapy

Treatment with carnitine has been reported to improve skeletal and heart muscle function to nearly normal in primary carnitine deficiency. It also corrects hepatic ketogenesis. Dose of carnitine is 100 mg/kg/day, should be started with low dose. Role of carnitine in secondary carnitine deficiency disorders remains controversial.

### Other Therapy

Dietary MCT is helpful in patients with LCHAD deficiency. Triheptanoin is suggested to be beneficial in VLCAD.

### Monitoring

Clinical assessment, measurement of acylcarnitines and FFA including essential fatty acids are useful indicators.

### Management of Acute Illness (Emergency Treatment)

When patients with FAOD become ill or with fever and irritability, they should be admitted in hospital. Treatment with IV fluids 10% dextrose in N/4 saline at infusion rates of 10 mg/kg/min should be given immediately to maintain high to normal levels of plasma glucose. Stop all natural protein intakes. Carnitine dose should be increased.

### Long-term Therapy (Maintenance Treatment)

Mainstay of therapy is to prevent period of fasting which would require fatty acids as a fuel. This can be done by educating the patients or parents to take adequate carbohydrate feeding specially at bedtime and do not fast more than 12 hours overnight. Riboflavin and carnitine should be given. Some studies recommend fat restriction, although this remains controversial.

## PROGNOSIS

Although acute illness is associated with high risk, many patients can be easily managed by avoidance of prolonged fasting. These patients have good prognosis. Patients with chronic disease have a more guarded prognosis.

### IN A NUTSHELL

1. Fatty acid oxidation defects in the neonate could present with SIDS, encephalopathy, hypoketotic hypoglycemia, cardiomyopathy, myopathy and rarely with certain dysmorphic features.
2. In infancy and childhood, other presentation could be as Reyes syndrome or with hepatic decompensation.
3. Severity of the defect also depends on its chain length, i.e., more with long-chain, less with medium-chain and least with short-chain defects.
4. Fasting, exercise, intercurrent illness and treatment with intuitive drugs can uncover an underlying defect.
5. Diagnosis can usually be established by acylcarnitine profile on tandem mass spectrometry and by dicarboxylic acids in urine or the glycine conjugates in urine. Mutation analysis is confirmatory and enzyme analysis using fibroblast cultures is important.

## Chapter 3.6

# Mitochondrial Disorders

Sheffali Gulati, Biswaroop Chakrabarty

Mitochondrial diseases are one of the most diverse, dynamic and evolving group of disorders in modern medicine. The presence of independent DNA in mitochondria was discovered in 1963, which is derived from the ovum and, hence, the inheritance of diseases with mitochondrial DNA defects is known as maternal or cytoplasmic. The differences in mitochondrial and nuclear DNA are enumerated in **Table 1**. Of the 37 genes present in mitochondrial genome, 13 encode for structural proteins in the respiratory chain and the remaining 24 (2 ribosomal and 22 transfer RNAs) are involved in protein synthesis.

There are 3 attributes of mitochondrial genome central to the manifestations of its dysfunction, namely *plasmidy*, *threshold effect* and *replicative segregation*. *Plasmidy* refers to the distribution of mutated and wild type genome (homoplasmy and heteroplasmy), *threshold effect* is the proportion of the mutated genome beyond which disease manifests (varies from disease to disease) and *replicative segregation* is the random redistribution of mitochondrial DNA during replication.

## GENETIC AND BIOCHEMICAL CLASSIFICATION OF MITOCHONDRIAL DISORDERS

Of the 80 proteins overall present in mitochondria, only 13 are encoded by mitochondrial DNA, rest all are nuclear DNA encoded proteins. Thus, genetically mitochondrial disorders are either of nuclear or mitochondrial origin. Biochemically, they manifest primarily as impaired protein synthesis or deficient respiratory chain complexes. The biochemical and genetic basis of common mitochondrial disorders are enumerated in **Table 2**.

## EPIDEMIOLOGY

Prevalence data for this rare group of disorders are lacking from across the world. This is because mitochondrial disorders represent a very heterogeneous group of diseases, both phenotypically as well as genotypically. Moreover, facilities for molecular studies of mitochondrial disorders are sparingly available across the world and, hence, it is an underdiagnosed entity. Because of high childhood mortality, incidence figures are more reliable than prevalence data. Keeping these issues under consideration and allowing for incomplete ascertainment, the lifetime risk of developing mitochondrial disease is to the tune of 1 in 5,000 livebirths. The most common pediatric mitochondrial disorder is Leigh's disease.

## ETIOPATHOGENESIS

The function of mitochondria is to convert the chemical energy of food to adenosine triphosphate (ATP), a process known as oxidative phosphorylation. This is mediated through the Krebs cycle and fatty acid  $\beta$ -oxidation pathways which generates nicotinamide adenine dinucleotide (NADH) and flavin adenine dinucleotide (FADH<sub>2</sub>), (both acting as potential electron donors) and the electrons from these reducing agents pass through the electron transport chain complex (comprising of five multiprotein complexes I-V) located in the inner mitochondrial membrane, creating a proton gradient, which mediates ATP synthesis.

Mitochondrial DNA is susceptible to oxidative damage because of the close vicinity to the place where reactive oxygen species are produced, lack of protective histone proteins and the limited availability of proofreading machinery. Certain nuclear DNA encoded factors are also required for mitochondrial biogenesis,

**Table 1** Differences between nuclear and mitochondrial DNA

Characteristics	Nuclear DNA	Mitochondrial DNA
Location	Nucleus	Mitochondria
Genomic constitution	$3 \times 10^9$ base pair/haploid genome	$1.6 \times 10^4$ base pair/genome
Introns	Present	Absent
Ploidy	Diploid in somatic cells	Polyploid
Chromosomal organization	23 linear chromosomes	One circular chromosome
Genes	23,000	37
Messenger RNAs	Encode all cellular functions	Only respiratory chain functions
Genetic code	Universal	Modified
Replication	Many symmetric replication origins	One asymmetric origin
Transcription	Monocistronic	Polycistronic

**Table 2** Biochemical and genetic basis of common mitochondrial disorders

Disorder	Biochemistry	Genetics
Kearns-Sayre syndrome	Impaired protein synthesis	Mitochondrial DNA
MELAS	Impaired protein synthesis	Mitochondrial DNA
MERRF	Impaired protein synthesis	Mitochondrial DNA
NARP/MILS	Impaired ATP synthesis	Mitochondrial DNA
LHON	Decreased complex I	Mitochondrial DNA
Leigh's syndrome	Decreased complex I/II/IV	Nuclear DNA
GRACILE	Decreased complex III	Nuclear DNA
Fatal infantile multisystemic disease	Decreased complex V	Nuclear DNA
MNGIE	Impaired protein synthesis	Nuclear DNA
PEO	Impaired protein synthesis	Nuclear DNA

**Abbreviations:** MELAS, mitochondrial encephalomyopathy, lactic acidosis and stroke-like episodes; MERRF, myoclonic epilepsy with ragged red fibers, NARP, neuropathy, ataxia and retinitis pigmentosa; MILS, maternally inherited Leigh's syndrome; ATP, adenosine triphosphate; LHON, Leber's hereditary optic neuropathy; GRACILE, growth retardation, aminoaciduria, cholestasis, lactic acidosis, early death; MNGIE, mitochondrial neurogastrointestinal encephalomyopathy; PEO, progressive external ophthalmoplegia.

assembly, mitochondrial DNA replication, transcription and translation. Mitochondria also plays major role in apoptosis, autophagy and free-radical turnover in the body.

The mutation rates in mitochondrial DNA are 10–20 times higher than that in nuclear DNA. The defects in mitochondrial DNA secondary to impaired mitochondrial genome are of 2 types, namely, point mutation and depletion. The most common diseases are secondary to point mutations.

The common mitochondrial disorders, the genes involved and their inheritance are enumerated in **Table 3**. Some common acquired causes of mitochondrial dysfunction are Reye's syndrome, toxin (MPTP: mitochondrial permeability transition pore), drugs (zidovudine) and aging.

**Table 3** Common mitochondrial disorders, the genes involved and their pattern of inheritance

Disorders	Gene involved	Inheritance
<i>Primary defect in mitochondrial genome</i>		
MELAS	m.3243A > G mutation in tRNA <sup>leu(uur)</sup>	M
MERRF	m.8344A > G mutation the tRNA <sup>lys</sup>	M
LHON	m.11778G > A mutation in ND1	M
NARP/MILS	m.8993T > G mutation in ATP6	M
<i>Primary defect in nuclear gene</i>		
Alpers' syndrome	POLG	AR
MNGIE	TP	AR
Leigh's syndrome	SURF1	AR
PEO	POLG, TWINKLE	AR/AD

**Abbreviations:** MELAS, mitochondrial encephalomyopathy, lactic acidosis and stroke-like episodes; MERRF, myoclonic epilepsy with ragged red fibers, NARP, neuropathy, ataxia and retinitis pigmentosa; MILS, maternally inherited Leigh's syndrome; ATP, adenosine triphosphate; LHON, Leber's hereditary optic neuropathy; MNGIE, mitochondrial neurogastrointestinal encephalomyopathy; PEO, progressive external ophthalmoplegia; M, mitochondrial; AR, autosomal recessive; AD, autosomal dominant.

## CLINICAL FEATURES

Defects in any of the 1,500 genes targeted towards mitochondria ultimately effect the organs with high energy demand, viz., muscle (skeletal, cardiac and smooth), nerve, brain, auditory and visual pathway, pituitary, pancreas, thyroid, kidney, liver and the immune system. The rule of thumb is that in involvement of three or more organ systems without any unifying disease, an underlying mitochondrial disorder should be considered. Red flag signs and symptoms that should raise the suspicion of mitochondrial disorder are listed in **Box 1**. Clinical features of some of the common mitochondrial disorders relevant to a pediatrician are being discussed here.

### BOX 1 Red flag clinical features for mitochondrial disorder

1. **Neurological:** Cognitive decline, recurrent episodic encephalopathy, movement disorder, epilepsy partialis continua, myoclonus, ataxia, sensorineural hearing loss.
2. **Cardiovascular:** Cardiomyopathy, arrhythmia.
3. **Ophthalmological:** Pigmentary retinopathy, optic atrophy, ptosis, ophthalmoparesis, impaired vision.
4. **Gastrointestinal:** Unexplained liver failure, pseudo-obstruction, dysmotility, cyclical vomiting.
5. **Endocrine:** Growth hormone deficiency, features of hypothyroidism and hypoparathyroidism.
6. **Renal:** Renal tubular acidosis, nephrotic syndrome.
7. **Constitutional:** Short stature, microcephaly, failure to thrive.

## Leigh's Syndrome

Most patients present with varying degrees of cortical, brain stem and basal ganglia dysfunction like encephalopathy, somnolence, ataxia, nystagmus, respiratory dysfunction, ataxia, dyskinesia and dystonia. Age at onset can vary from neonatal period to later in life. The neonatal onset is associated with facial dysmorphism and the later ones usually have episodic deterioration.

## MELAS (Mitochondrial Encephalomyopathy, Lactic Acidosis and Stroke-like Episodes)

MELAS is the prototypical mitochondrial disease presenting with stroke in individuals younger than 45 years with predilection for involvement of parietal and occipital lobes. These lesions are

usually very epileptogenic and patients may present with epilepsy partialis continua (EPC). Other associated clinical features include migraine with aura, exercise intolerance, progressive external ophthalmoparesis and visual hallucinations.

## MERRF (Myoclonic Epilepsy with Ragged Red Fibers)

This disorder represents the prototype progressive myoclonic epilepsy phenotype amongst mitochondrial disorders. Clinically the salient features are progressive cerebellar symptoms, generalized seizures, myoclonus, cognitive decline, central hearing loss, optic atrophy and short stature.

## Alpers Syndrome

A triad of intractable seizures (usually EPC), psychomotor deterioration and liver failure (worsening with valproate) characterizes this disorder. Onset is usually at any time from 1 month of age to 25 years. Usually the onset is in early childhood with most patients dying by the age of 3 years. The late onset variant is also characterized by a peripheral sensory neuropathy.

## Kearns-Sayre Syndrome (KSS)

The criteria for labeling a patient with KSS include onset before the age of 20; progressive external ophthalmoparesis; and salt and pepper pigmentary retinopathy, plus any one of the following: complete heart block, cerebellar ataxia and cerebrospinal fluid more than 100 mg/dL. Other associated features include cognitive decline, sensorineural hearing loss, optic atrophy, multiple endocrine abnormalities, renal tubular acidosis and Lowe syndrome.

## LHON (Leber's Hereditary Optic Neuropathy)

This entity is characterized by sudden onset usually progressive unilateral or bilateral painless vision loss secondary to optic atrophy in adolescence or early adulthood. It affects males more than females.

## LABORATORY EVALUATION

There is no uniform standard set of guidelines for biochemical or metabolic studies in diagnosing mitochondrial disorders. Enzymatic assays are not standardized among diagnostic centers. Tissue diagnosis, although preferable, is limited by geographical constraints. Although molecular studies have better inter- and intralaboratory reproducibility, low levels of disease causing heteroplasmy may remain undetected in peripheral blood.

## Biochemical Investigations

Blood investigations include complete blood count, liver and kidney function tests, serum ammonia and electrolytes. Elevated fasting arterial and cerebrospinal fluid lactate (beyond 2.1 mmol/L) is a nonspecific marker of mitochondrial disease, at times only seen during an acute crisis. Certain disorders like LHON, KSS, mitochondrial DNA polymerase gamma (POLG1) associated diseases and Leigh's disease have normal lactate most of the time. Spurious elevations of lactate also happen if there is a lot of struggle in obtaining blood sample from a child or tourniquet is placed for a prolonged period while sampling. The ideal way to do it would be to collect the sample 30 minutes after placement of the intravenous catheter. It is more useful to estimate the lactate to pyruvate ratio. However, sample drawn for pyruvate has to be immediately (within 30 seconds) stored in 8% perchlorate ice and then analyzed. Lactate or pyruvate ratio of less than 25 in the setting of lactic acidemia points towards the diagnosis of pyruvate dehydrogenase deficiency or gluconeogenic defects, whereas a value of greater than 25 indicates respiratory chain defects or pyruvate carboxylase deficiency.

Although fasting serum amino acid estimation (tandem mass spectrometry, TMS), particularly alanine, is not a very sensitive tool to diagnose mitochondrial disorder, it can be useful in oxidative phosphorylation disorders as it is less prone to get changed by improper collection methods. Other amino acids which may be elevated are proline, glycine and sarcosine. TMS also yields acylcarnitine and carnitine values which may denote secondary carnitine deficiency and impaired fatty acid oxidation with underlying oxidative phosphorylation defects.

Urine gas chromatography and mass spectrophotometry may show tricarboxylic acid intermediates and dicarboxylic aciduria consequent to underlying secondary impaired fatty acid oxidation.

## Invasive Tissue Investigations

### Skeletal Muscle Analysis

Ragged red fibers (RRF) seen as subsarcolemmal red granular deposits against a background of atrophic muscle fibers on modified gomori trichrome staining indicate abnormal mitochondrial proliferation (**Fig. 1**). However, this is also seen at times in muscular dystrophies, metabolic, inflammatory and congenital myopathies. Other histochemical stains which increase the diagnostic yield are NADH dehydrogenase, cytochrome C oxidase [cytochrome C oxidase (COX), evaluates complex IV] and succinate dehydrogenase (SDH, evaluates complex II). RRF with low COX activity with strong SDH staining is

**Figure 1** Modified Gomori trichrome stain of muscle biopsy showing ragged red fiber (MGT x 400)

**Figures 3A to D** Electromicrophotographs of muscle biopsy showing (A) paracrystalline inclusion; (B) finger print like inclusions; (C) parking lot inclusions; and (D) zipper like inclusions in the mitochondria

Source: Dr MC Sharma, Professor, Pathology, AIIMS, New Delhi

seen in KSS, MERRF and progressive external ophthalmoplegia (PEO) (**Fig. 2**), whereas RRF with normal COX staining is seen in MELAS. Electron microscopy shows ultrastructural changes like increased mitochondrial number and size, distorted or decreased cristae, osmophilic, paracrystalline, fingerprint, parking lot and zipper like inclusions (**Figs 3A to D**). Skeletal muscle biopsy can also be used to estimate mitochondrial enzymes and coenzyme Q10 and extraction of DNA for molecular studies.

### Other Tissues

Liver and skin fibroblast can be used occasionally for enzyme analysis and DNA testing (POLG in liver biopsy).

### Neuroimaging

A wide spectrum of neuroimaging changes are seen in mitochondrial disorders. Diffuse cerebral (complex V defect) and cerebellar atrophy (Alpers syndrome) can be seen. Bilateral basal ganglia, brainstem including periaqueductal gray matter and substantia nigra, diencephalon and cerebellar lesions are seen in Leigh's syndrome (**Fig. 4**). MELAS usually shows multifocal gray matter involvement predominantly in the parieto-occipital region without conforming to any vascular territory. Leukodystrophy like picture is seen in electron transport chain defects and mitochondrial neurogastrointestinal encephalomyopathy (MNGIE). Patients with mitochondrial disorder may have cerebral lactic acidosis

without any peripheral blood lactic acidemia. Magnetic resonance spectroscopy of the brain with appropriate voxel placement offers a suitable alternative to cerebrospinal fluid lactate estimation as it produces a negative lactate peak (1.33 ppm) in mitochondrial cytopathies with cerebral lactic acidosis (**Fig. 4C**).

### Molecular Testing

For the recurrent common mitochondrial point mutations, the methodology usually employed is either polymerase chain reaction (PCR) or restriction fragment length polymorphism, PCR or allele-specific oligonucleotide dot-blot analysis, allele refractory mutation system or direct sequencing. As 75–90% of the mitochondrial disorders are mediated through nuclear genes, sequence analysis of a group of candidate genes is also helpful. Even with all these advance techniques, only around 10% of the candidate genes for mitochondrial disorders are currently identifiable. So, the current ongoing research effort for increasing the diagnostic yield is development of a high throughput sequencing technology which can identify and quantify majority of nuclear and mitochondrial genomic mutations.

### Ancillary Diagnostic Modalities

Echocardiography, electrocardiogram, detailed ophthalmological and audiological investigation should be tailored for each patient on an individual basis.

**Figures 4A to C** MRI brain (T2 weighted images) of a Leigh's disease patient showing (A) bilateral basal ganglia; (B) brain stem hyperintensities with; (C) MR spectroscopy from the basal ganglia lesion showing characteristic inverted lactate peak

## TREATMENT

Apart from symptomatic treatment of various organ system effects, there is no established, standard of care treatment protocol for mitochondrial disorders. Extensive research is underway both at the level of animal as well as human models. These novel therapeutic strategies are being developed targeting the following pathways:

- **Preventing transmission of defective mitochondrial DNA** This approach, also known as germline therapy, is aimed at preventing maternal transmission of disease mitochondrial DNA to the child.
- **Modifying heteroplasmy levels** The pathological threshold levels of mutated mitochondrial DNA can be reduced by degrading selectively the mutated DNA or enrichment of the wild type DNA.
- **Replacement of defective mitochondrial DNA, tRNA and proteins** This utilizes the technique of protein transduction, which is a novel strategy to transport target mitochondrial sequence across the membranes and localize within the mitochondria.
- **Utilization of vitamins and cofactors** Various agents like dichloroacetate (in conditions with lactic acidosis like MELAS), coenzyme Q and its congeners mitoQ and idebenone (for electron transport chain defects), L-arginine (MELAS), folinic acid (KSS), carnitine, creatine, thiamine, riboflavin, vitamins C and E, dihydrolipoate and glutathione have been tried as free radical scavengers or remover of toxic metabolites or electron acceptors or as vitamins and cofactors with encouraging reports; however, a recent Cochrane review has emphasized the need for further well designed, adequately numbered studies for definite conclusive role.
- **Optimizing ATP synthesis** The fact that mitochondrial disorders retain some residual minimal oxidative phosphorylation activity has been utilized by either modulation of mitochondrial calcium levels, increasing mitochondrial biogenesis or by allosteric activation of protein kinase A.
- **Bypassing oxidative phosphorylation defects** Animal models have explored alternate pathways for bypassing oxidative phosphorylation.

The summary of therapeutic approaches in mitochondrial disorders is enumerated in **Table 4**.

### IN A NUTSHELL

1. The lifetime risk of developing mitochondrial disease is around 1 in 5,000 livebirths.
2. Primary mutations in mitochondrial DNA are either due to point mutations or deletions, whereas in nuclear DNA mediated cases, it is secondary to multiple deletions or depletions.
3. The most common pediatric mitochondrial disorder is Leigh's disease. Other common mitochondrial disorders are MELAS (mitochondrial encephalomyopathy, lactic acidosis and stroke-like episodes), MERRF (myoclonic epilepsy with ragged red fibers), Alpers' syndrome, Kearns-Sayre syndrome, and Leber's hereditary optic neuropathy.
4. Red flag clinical features for mitochondrial disorders exist, whenever 3 or more organ systems are involved without any unifying pathology, mitochondrial disorder should be suspected.
5. Currently noninvasive and invasive baseline biochemical investigations and neuroimaging can direct to appropriate molecular testing, which can diagnose up to 10% of cases.
6. Apart from symptomatic treatment, as of now, there is no standard of care treatment protocol for mitochondrial disorders.

**Table 4** Summary of therapeutic approaches in mitochondrial disorders

Therapeutic strategy	Components
Preventing transmission of defective mitochondrial DNA	Cytoplasmic transfer Pronuclear transfer
Modifying heteroplasmy	Selective degradation of mitochondrial DNA (restriction endonucleases, zinc finger nucleases) Enrichment of wild type DNA (ketogenic diet, resistant exercise)
Replacement of defective mitochondrial DNA, tRNA and proteins	Protofection Recombinant virus-mediated gene transfer Targeted tRNA import Allotropic expression
Vitamins and cofactors	Dichloroacetate (in conditions with lactic acidosis like MELAS), coenzyme Q and its congeners mitoQ and idebenone (for electron transport chain defects), L arginine (MELAS), folinic acid (KSS), carnitine, creatine, thiamine, riboflavin, vitamins C and E, dihydrolipoate and glutathione
Optimizing ATP synthesis	Modulation of mitochondrial calcium levels Mitochondrial biogenesis Allosteric activation
Bypassing oxidative phosphorylation defects	Rotenone insensitive NADH dehydrogenase Cyanide insensitive alternative oxidase

**Abbreviations:** MELAS, mitochondrial encephalomyopathy; NADH, nicotinamide-adenine dinucleotide; KSS, Kearns-Sayre Syndrome.

## Chapter 3.7

# Peroxisomal Disorders

Madhulika Kabra, Neerja Gupta

Peroxisomal disorders, more appropriately addressed as peroxisomal biogenesis disorders (PBD) are a group of disorders with highly heterogeneous phenotype. Majority of the disorders are autosomal recessive except adrenoleukodystrophy (ALD) which is X-linked recessive. In peroxisomal disorders, the assembly of peroxisomes is impaired which results in complex enzyme abnormalities causing diverse phenotypes. Three broad phenotypic groups and many atypical phenotypes have been described.

Common disorders amongst these include X-linked ALD, Zellweger syndrome (ZS), neonatal ALD, infantile Refsum disease, and rhizomelic chondrodysplasia punctata (RCDP). Diagnosis is complicated and is based on biochemical studies and molecular tests. ALD is the most common of the peroxisomal disorders, affecting about one in 20,000 males. ZS is rare affecting one in 50,000–100,000 livebirths.

## PATHOPHYSIOLOGY

Peroxisomes are single membrane-bound organelles which are small and spherical or oval in shape. These are present in large numbers in each cell. A peroxisome must contain catalase enzyme which breaks down hydrogen peroxide. The pathophysiology is complex and involves many pathways. This is evident by the fact that as many as 50 different biochemical reactions take place in a peroxisome. These include both anabolic and catabolic reactions. During  $\beta$ -oxidation in the peroxisomes, very long-chain fatty acids (VLCFA) are utilized ( $> C22$ ) but the reaction is not completed and ends in shorter fatty acids that are then transported to mitochondria for complete oxidation.

There are 16 *PEX* genes involved in this complex system. Mutations in 14 of these genes cause various PBD. All *PEX* genes except *PEX 7* cause Zellweger spectrum disorder (ZSD). The protein product is peroxin and usually the severity of the disorder correlates well with the type and consequence of mutations, residual enzyme function and number of peroxisomes.

## CLASSIFICATION

These disorders can be broadly classified in two groups, namely assembly or biogenesis deficiencies and single enzyme deficiency. In assembly deficiency, there is loss of multiple enzyme activities leading to abnormal morphology of organelle. In most of these disorders, there is defect in importing the protein in the peroxisomes. In the single enzyme defect, only one enzyme is involved and the structure of the peroxisome is not disrupted. Classification of these disorders is listed in **Box 1**.

### BOX 1 Classification of peroxisomal disorders

1. Assembly deficiencies
  - Zellweger syndrome
  - Infantile Refsum disease
  - Hyperpipecolic acidemia
  - Rhizomelic chondrodysplasia punctata (classical type)
  - Neonatal adrenoleukodystrophy
  - Pseudo-infantile Refsum disease
  - Zellweger-like syndrome
2. Single enzyme deficiency
  - Single peroxisomal enzyme deficiency involving oxidation pathway
    - X-linked adrenoleukodystrophy (ALD protein)
    - Pseudoneonatal adrenoleukodystrophy (Acyl-CoA oxidase)
    - Pseudo-Zellweger (Thiolase)
    - Bifunctional enzyme deficiency (bifunctional protein)
  - Single peroxisomal enzyme deficiency without involving oxidation pathway
    - Refsum disease (phytanic acid oxidase)
    - Pseudo-rhizomelic chondrodysplasia (plasmalogen synthesis)
    - Di-(tri)-hydrocholestanic acidemia (bile acid synthesis)
    - Mevalonic aciduria (cholesterol synthesis)

Laboratory diagnosis is usually based on studying function of the peroxisome and molecular studies. **Table 1** summarizes the diagnostic strategy for PBD. Common disorders are discussed below. ALD is detailed in Section 42, chapter 42.26 on Neurodegenerative diseases.

## ZELLWEGER SYNDROME

This syndrome has a characteristic phenotype when presenting as a classical form. It is also called cerebrohepatorenal syndrome. The inheritance is autosomal recessive.

**Table 1** Laboratory work-up for peroxisomal disorders

Test	Metabolite/gene	Disorder	Comments
Plasma VLCFA	Increased C26:0, C26:1 and C24/C22, C26/C22 ratio	ZS, NALD, IRD	May be false positives in patients on ketogenic diet, and in hemolyzed samples; normal in RCDP1
Plasma phytanic and pristanic acid	Increased	ZS, NALD, IRD, RCDP1 (phytanic only)	Normal in neonatal period as accumulates after dietary intake
RBC plasmalogens	Decreased	ZS, NALD, IRD, RCDP1	Most significant reduction in RCDP1
Plasma pipecolic acid	Increased	ZS, NALD, IRD	Adjunct to other metabolites
Cultured fibroblasts	Enzyme assay, abnormal metabolites	ZS, NALD, IRD, RCDP1	Though confirmatory but not easily available
Molecular genetic testing	<i>PEX1</i> , 2, 3, 5, 6, 10, 11b, 12, 13, 14, 16, 19, 26	ZS, NALD, IRD	80% of cases with ZSD are due to defects in <i>PEX1</i> , 2, 6, 10, 12, 26
	<i>PEX 7</i>	RCDP1	Four common <i>PEX7</i> alleles in exons 7 and 9 account for 70% of cases of RCDP1

**Abbreviations:** VLCFA, very long-chain fatty acids; ZS, Zellweger syndrome; NALD, neonatal adrenoleukodystrophy; IRD, infantile Refsum disease; RCDP1, rhizomelic chondrodysplasia punctate; ZSD, Zellweger spectrum disorder.

**Source:** Adapted from Braverman, et al. Dev Disabilities Res Rev. 2013.

## Clinical Features

The usual presentation is in the neonatal period with a recognizable clinical phenotype of high forehead with widely open anterior fontanel, flat facial profile with hypertelorism and epicanthic folds (at times confused with Down's syndrome), small chin and high arched palate. Severe hypotonia is an important clinical sign. These babies often have seizures. Other manifestations include direct hyperbilirubinemia, liver dysfunction and hepatomegaly, cataract, glaucoma, pigmentary retinopathy, hearing loss, renal stones and poor weight gain. **Figure 1** shows typical phenotype of a baby with ZS. All patients with classical ZS die in the first few months of life.

## Investigations

Magnetic resonance imaging of brain may show neuronal migration defects like polymicrogyria (typically lateral), pachygyria (medial) and heterotopias. X-rays may show chondrodysplasia punctata. The diagnosis is confirmed by analysis of plasma VLCFA and plasmalogens in red blood cells. Plasma VLCFA shows increased C26:0, C26:1 and C24/C22, C26/C22 ratio, increased phytanic acid and pipelicolic acid, and reduced RBC plasmalogens. Increased urine and plasma bile acid intermediates are also reported. Cultured fibroblasts may be used for enzyme assays. Molecular genetic studies involve mutation analysis of *PEX1*, 2, 3, 5, 6, 10, 11b, 12, 13, 14, 16, 19, 26 as mutations have been reported in all these genes. However, defects in *PEX1*, 2, 6, 10, 12, 26 account for approximately 80% of cases with ZS.

## Treatment

Management is symptomatic and multidisciplinary. No curative therapy is available. Dietary interventions by restriction of accumulated metabolites and supplementation of deficient ones has been tried but with no conclusive results. Oral bile acid therapy has been reported to improve hepatobiliary function. Restriction of phytanic acid has also been tried.

Prenatal diagnosis is opted by most families in view of the nature of disease and high recurrence risk of 25%. Prenatal testing can be offered by analysis of amniotic fluid or chorionic villus sampling (CVS) using cultured cells for biochemical markers or by mutation testing of the fetal DNA sample.

**Figure 1** A neonate with Zellweger syndrome. Note flat facial profile, hypertelorism with epicanthic folds and high forehead

## RHIZOMELIC CHONDRODYSPLASIA PUNCTATA

### Clinical Features

This is another severe and easily recognizable disorder. The disorder presents in early life with shortening of the proximal part of the long bones affecting femur more than the humerus and typical facial features. These include frontal bossing, midface hypoplasia and small nose with depressed nasal bridge. Cataracts are either noticed at birth or develop early. Failure to thrive, seizures and developmental delay are also seen. **Figure 2A** shows clinical features of RCDP. Occasional patients are reported to have cleft palate, renal malformations and congenital heart defects. Some children die in the first year of life but individuals with milder forms may survive.

Three types of RCDP are described with similar phenotype but different pathogenesis. RCDP1 being caused by mutations in *PEX 7* genes while RCDP2 and RCDP3 are due to defects in peroxisomal enzymes.

### Investigations

Skeletal survey shows generalized calcific epiphyseal stippling referred to as chondrodysplasia punctata (**Fig. 2B**). This may disappear with time. MRI brain does not show characteristic abnormalities as reported in ZS but nonspecific changes may be seen including cerebellar degeneration. Confirmation of diagnosis is by biochemical analysis of plasma as in ZS. RBC plasmalogen levels are very significantly reduced particularly in RCDP1, plasma VLCFA is not increased and phytanic acid is reduced (**Box 1**). Mutations in *PEX7* gene commonly in exons 7 and 9 account for approximately 70% of cases of RCDP1.

Treatment is supportive and symptomatic. Prenatal diagnosis is possible by biochemical analysis of amniotic fluid or molecular testing.

## NEONATAL ADRENOLEUKODYSTROPHY

Neonatal ALD is a peroxisomal disorder with intermediate severity and is autosomal recessive in inheritance.

### Clinical Features

These patients present with hypotonia, seizures, encephalopathy, visual and hearing abnormalities with onset at birth or early infancy but may not be diagnosed due to nonspecific phenotype. Leukodystrophy may develop around 3–5 years and may

**Figures 2A and B** (A) Baby with characteristic features (flat facies, smooth long philtrum, thin upper lip, joint contractures at elbow and knee) rhizomelic chondrodysplasia punctata; (B) Arrow shows the epiphyseal stippling at knee

manifest as neuroregression. Other features include peripheral neuropathy, poor growth, developmental delay and facial dysmorphism which may be subtle with mid-face flattening and hypertelorism. Eye findings include cataract, optic nerve dysplasia and chorioretinopathy. Some patients may have hepatic dysfunction and even coagulopathy.

### Investigations

Magnetic resonance imaging scan may show leukodystrophy, neuronal migration defects or other malformations. Active demyelination is seen in the cerebrum, midbrain and cerebellum. Definitive diagnosis requires biochemical studies or molecular testing. Plasma VLCFA are elevated particularly C26:0 and C26:1 and elevated ratios of C24/C22 and C26/C22. RBC plasmalogens are reduced. Plasma pipecolic acid levels and bile acid intermediates are elevated. Sequence analysis of the 13 *PEX* genes can give confirmatory diagnosis.

### Management

Prenatal diagnosis can be offered by culturing the amniocytes and CVS for VLCFA and plasmalogen synthesis. If causative mutations are identified, prenatal diagnosis can be offered using molecular tests.

There is no cure and treatment is symptomatic. Hepatic coagulopathy can be treated with vitamin K supplementation and liver function may improve with primary bile acid therapy. Foods rich in phytanic acid may be restricted. Standard epileptic drugs are used for seizures.

Prognosis is poor with most patients dying in infancy and early childhood. Some have lived until their teenage years.

### REFSUM DISEASE

This disease has a variable onset of symptoms usually in late childhood or adolescence, but may present even in later life. Acute and subacute progression has been reported in few cases but it usually follows a chronic progressive course.

### Clinical Features

Important clinical features include a demyelinating neuropathy which may be associated with hypertrophy of nerves. Other manifestations include pes cavus, cerebellar ataxia, sensorineural deafness, anosmia and cranial nerve involvement. Visual problems in the form of night blindness are present due to retinitis pigmentosa. Cataracts and photophobia are also reported. Other manifestations like miosis may be due to generalized dysautonomia. Cardiac conduction abnormalities have also been reported which may be life-threatening. Skin may show rough, thick scaly lesions. Epiphyseal dysplasia may present as characteristic shortening of the fourth toe, which may be an important diagnostic clue.

Differential diagnosis includes Friedreich ataxia, mitochondrial cytopathies, other hereditary motor and sensory neuropathies, and vitamin E deficiency.

### Investigations

Nerve conduction studies demonstrate slowing of conduction velocities. Cerebrospinal fluid protein levels may be high. Due to retinal pigmentary changes, electroretinogram may be abnormal. Nerve biopsies, though usually not resorted to, may show *onion bulb* appearance and other inclusions. Confirmation of diagnosis is by measuring plasma levels of phytanic acid using gas chromatography-mass spectroscopy, which are significantly elevated as compared to other ZSD. Pristanic acid is low/normal in Refsum disease due to lack of production from phytanate (Table 1). Mutations in the *PEX* genes have been reported to cause RCDP.

### Treatment

Refsum disease is amenable to dietary therapy and may show partial improvement if started early. Restriction of phytanic acid has been reported to be useful. It is easily possible as phytanic acid is almost exclusively of exogenous origin. Important sources include fish, beef, lamb, dairy products and vegetables. The average daily intake of phytanic acid is about 50–100 mg/day, and the recommendation is to reduce it to 10–20 mg/day. This may affect palatability and, hence, compliance. The neurological, cardiac and dermatological sequelae can be reversed by reduction of phytanic acid levels, but the visual and hearing impairments are less responsive to treatment. In acutely presenting cases, plasma phytanic acid level may be reduced by plasma exchange with a significant clinical improvement. Dietary treatment has to be continued lifelong.

### ATYPICAL PHENOTYPES

Atypical presentations of ZSD are now being reported and patients may have preserved intellect. These include the following:

- Cerebellar ataxia, with or without peripheral neuropathy, and relative preservation of intellect. MRI brain may show cerebellar atrophy.
- Another group including patients have no cognitive defects but present with progressive spastic paraparesis and ataxia in early childhood. MRI shows cerebellar trophy and cerebral leukodystrophy. These patients may develop peripheral neuropathy later.
- A lethal phenotype with microcephaly, optic atrophy and lactic acidemia has also been reported. MRI brain showed dysmyelination and abnormal gyration.

### IN A NUTSHELL

1. In peroxisomal disorders, the assembly of peroxisomes is impaired which results in complex enzyme abnormalities causing diverse phenotypes.
2. Common disorders among these include X-linked ALD, ZS, neonatal ALD, infantile Refsum disease and RCDP.
3. Zellweger syndrome can be clinically confused with Down's syndrome.
4. Diagnosis can be made by plasma biochemical studies and DNA-based tests.
5. Most disorders are untreatable except Refsum disease and very early stages of ALD.

## Chapter 3.8

# Lysosomal Storage Disorders

IC Verma

Lysosomes, initially discovered by Christian de Duve in 1955, are organelles in the cytosolic compartment of the cell. They contain acid hydrolytic enzymes, which are synthesized in the rough endoplasmic reticulum (rER), fold in a specific way so that an N-terminal signal patch is formed, which allows for further modification by the addition of mannose-6-phosphate (M-6-P). The enzymes then move across the ER membrane to the lumen of the ER. From here, they proceed to the trans-Golgi network (TGN) where the lysosomal enzymes are sorted and packaged into vesicles, later transported to the early or late endosomes. Here dissociation occurs; the hydrolases translocate into the lysosome and the receptor is recycled either to the Golgi apparatus or to the plasma membrane. **Figure 1** illustrates the synthesis and cycling of lysosomes.

The lysosomal enzymes are involved in the breakdown and recycling of macromolecules, such as glycos-aminoglycans, glycoproteins, oligosaccharides and lipids. The micromolecules formed after breakdown are either reused by the cell or are eventually eliminated from the body. The lysosomes are thus the catabolic centers of the cell.

For degradation of cellular material, lysosomes use four distinct pathways: (A) Macroautophagy starts with the formation of isolation membranes that sequester regions of the cytosol containing denatured proteins, lipids, carbohydrates and old or damaged organelles into encapsulated vesicles known as autophagosomes. These are then cleared by the lysosomes; (B) The endosomes engulf the waste material, and fuse with lysosomes for final disposition; (C) Microautophagy involves the pinocytosis of cytosolic regions surrounding lysosomes that contain micromolecules; (D) Chaperone-mediated autophagy

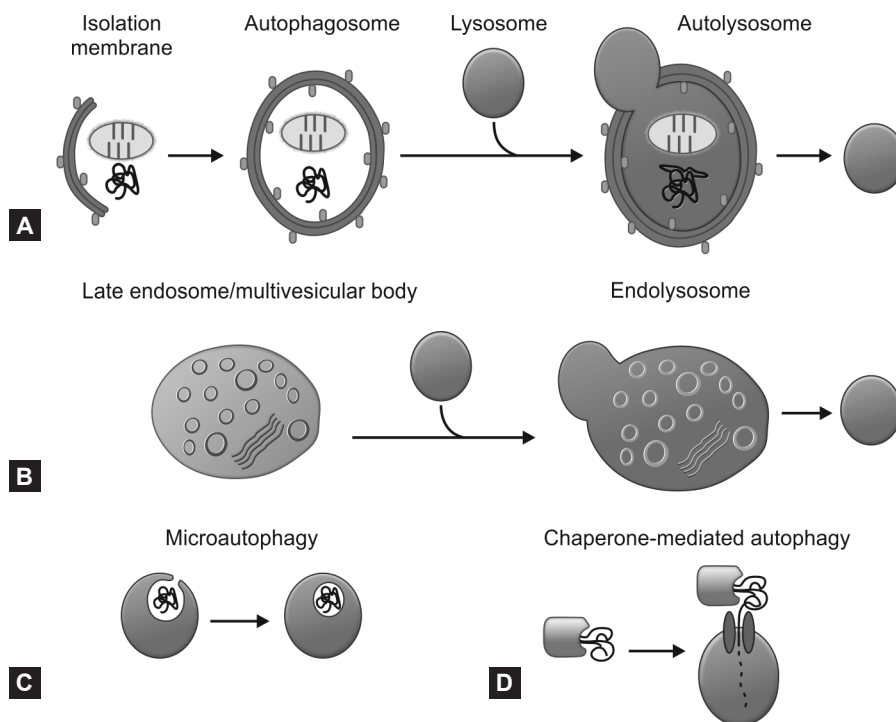

**Figure 1** Synthesis and movement of lysosomal enzymes  
Adapted from Ross, Michael H. *Histology: A Text and Atlas with Correlated Cell and Molecular Biology*, 5<sup>th</sup> ed. Lippincott Williams & Wilkins, 2005.

(CMA) selectively targets proteins with a KFERQ motif for delivery to lysosomes using Hsc-70 as its chaperone and LAMP-2A as its receptor. These pathways of degradation are depicted in **Figure 2**.

## EPIDEMIOLOGY

The lysosomal storage disorders (LSDs) are categorized according to the type of substrate that accumulates [e.g., mucopolysaccharidoses (MPSs), oligosaccharidoses, sphingolipidoses, gangliosidoses, etc.], or the type of enzyme defect. Over 70 lysosomal disorders

**Figure 2** Lysosomes as catalytic centers of the cell  
Adapted from Platt et al. *J Cell Biol.* 2012.

have been recognized. Individually, they are rare but collectively they have a prevalence of 1 in 5,000 population worldwide. The true figure is likely to be greater when undiagnosed or misdiagnosed cases are included. In India, the incidence is expected to be higher due to consanguinity and endogamous marriages in large sections of the population. This frequency makes LSD a disease category that a pediatrician is likely to come across in medical practice.

Two disorders of ganglioside biosynthesis have been genetically proven in the human population within the past decade—GM2-synthase deficiency which results in spastic paraplegia (progressive lower limb weakness and spasticity), and GM3-synthase deficiency, which was discovered in the Old Order Amish community in Ohio, and presents as a severe epilepsy syndrome.

All the LSDs are inherited in an autosomal recessive fashion, except four—Fabry, Hunter (MPS type II) and Danon disease, and a variant type of adult NCL (Kuf disease), which are X-linked. Some disorders are more prevalent among particular population groups (e.g., Gaucher and Tay-Sachs disease are more common in Ashkenazi Jews, due to ancestral founder mutations). For many diseases, such as Fabry, most families have private mutations. Founder mutations in some lysosomal disorders have been identified among Indian populations (e.g., Hexosamine A mutations in Gujarat), although more studies are required.

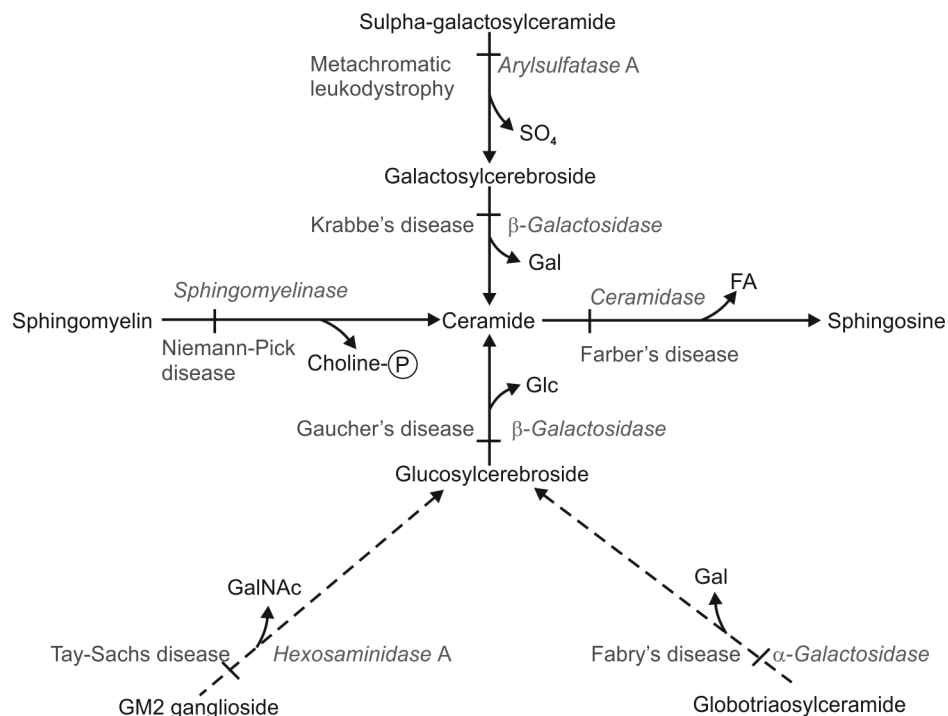

## ETIOPATHOGENESIS

Classical LSDs result from abnormalities in the gene coding for the specific acidic hydrolase enzyme, or its receptor, which leads to a deficient activity of the enzyme. As a result, the relevant substrate accumulates in a progressive manner within the lysosome. The physical enlargement of the lysosome, when it reaches a critical level, leads to dysfunction of multiple organelles in the cell, and eventually results in the enlargement of specific organ involved, leading to symptomatic disease. The dysfunction is due to the initiation of a complex downstream pathogenic cascade, the steps of which are only partially determined. Several studies in mouse models of LSDs involving ganglioside storage (for example,

Sandhoff disease and GM1 gangliosidosis) have provided evidence for a form of programmed cell death called caspase-dependent apoptosis. Other studies have uncovered an unusual cell-death mechanism in two sphingolipid storage diseases, type 2 Gaucher disease and Krabbe disease—necroptosis. This pathway is dependent on the kinases RIPK1 and RIPK3, and these mediate caspase-independent cell death.

Most LSDs result from deficiency of acidic hydrolase enzymes as mentioned above. However, some disorders result from defects in lysosomal membrane proteins (such as defective GM3-synthase in GM3-gangliosidosis), or by trafficking defects (Niemann-Pick disease, type C), or due to faulty lysosome-associated membrane protein 1 (LAMP-1), or LAMP-2, as in Danon disease and action myoclonus-renal failure syndrome, respectively. Under this categorization, neuronal ceroid-lipofuscinosis (NCLs) can also be included in the LSD spectrum.

The pathways in sphingolipidosis and the resultant disorders are depicted in **Figure 3**. In the glycol-sphingolipids, the central piece is the ceramide backbone (2-N-acylsphingosine), which is modified by the addition of a carbohydrate head group. The various sphingolipids are derived by substitution of hexoses, phosphorylcholine, or one or more sialic acid residues on the terminal hydroxyl group of the ceramide molecule. The simplest GSLs have a single monohexoside (glucose or galactose) moiety linked to ceramide. Over evolutionary time, the carbohydrate head group has increased in complexity—more than 300 structures have been described, with those derived from the core structure glucosylceramide (GlcCer) being the most common. Galactosylceramide (GalCer) and its sulfated derivative have a much more restricted distribution and are generally confined to myelin and the kidney. When the oligosaccharide head group of GlcCer-derived GSLs contains a sialic acid, the GSL is charged, and these GSLs are termed gangliosides and are the major glycoconjugates found in the nervous system. The complexity of sphingolipids is not just the result of the glycan head group, but also the ceramide chain-length heterogeneity that arises owing to the differential chain-length specificity of ceramide synthases.

**Figure 3** Sphingolipids showing ceramide and its derivatives and the enzymes involved

Progressive lysosomal accumulation of glycosphingolipids in the central nervous system (CNS) leads to neurodegeneration, whereas storage in visceral cells results in organomegaly, skeletal abnormalities, pulmonary infiltration, and other manifestations. Although the enzymes are expressed in many parts of the body, however, the accumulation occurs only in cells where the substrate is available. Therefore, only some organs are affected in certain types of LSDs. Liver, spleen and bone marrow are commonly involved organs, e.g., in Gaucher disease. The neurologic system is the most involved in diseases like Gm2 gangliosidosis or Krabbe disease.

## CLASSIFICATION

Lysosomal storage disorders can be grouped according to various classifications. In the past, they were classified on the basis of the

nature of the accumulated substrate(s), more recently they have tended to be classified by the molecular defect (**Table 1**).

## Clinical Phenotypes

The age of clinical onset and spectrum of symptoms exhibited by different LSDs vary, depending on the degree of cellular function affected by specific mutations, the biochemistry of the stored material, and the cell types where storage occurs. Apart from lysosomal diseases involving substrate storage in bone and cartilage (e.g., the MPSs), most babies born with these conditions appear normal at birth. LSDs present either with organomegaly or as a neurodegenerative disease of infancy/childhood, but adult-onset variants also occur.

The different types of substrate stored, the different cell types affected by storage, as well as the resultant differences in organ

**Table 1** Lysosomal storage disorders

Disease	Defective protein	Main storage materials	Gene involved
<i>Mucopolysaccharidoses (MPSs)</i>			
MPS I (Hurler, Scheie, Hurler/Schie)	$\alpha$ -Iduronidase	Dermatan sulfate, heparan sulfate	IDUA
MPS II (Hunter)	Iduronate sulfatase	Dermatan sulfate, heparan sulfate	IDS
MPS III A (Sanfilippo A)	Heparan sulfamidase	Heparan sulfate	SGSH
MPS III B (Sanfilippo B)	Acetyl $\alpha$ -glucosaminidase	Heparan sulfate	NAGLU
MPS III C (Sanfilippo C)	Acetyl CoA: $\alpha$ -glucosaminide N-acetyltransferase	Heparan sulfate	HGSNAT
MPS III D (Sanfilippo D)	N-acetyl glucosamine-6-sulfatase	Heparan sulfate	GNS
MPS IV A (Morquio A)	Acetyl galactosamine-6-sulfatase	Keratan sulfate, chondroitin 6-sulfate	GALNS
MPS IV B (Morquio B)	$\beta$ -Galactosidase	Keratan sulfate	GLB1
MPS VI (Maroteaux—Lamy)	Acetyl galactosamine 4-sulfatase (arylsulfatase B)	Dermatan sulfate	ARSB
MPS VII (Sly)	$\beta$ -Glucuronidase	Dermatan sulfate, heparan sulfate, chondroitin 6-sulfate	GUSB
MPS IX (Natowicz)	Hyaluronidase	Hyaluronan	HYAL1
<i>Sphingolipidoses</i>			
Fabry	$\alpha$ -Galactosidase A	Globotriasylceramide	GLA
Farber	Acid ceramidase	Ceramide	ASAH1
Gangliosidosis GM1 (Types I, II, III)	GM1- $\beta$ -galactosidase	GM1 ganglioside, Keratan sulfate, oligos, glycolipids	GLB1
Gangliosidosis GM2, Tay-Sachs	$\beta$ -Hexosaminidase A	GM2 ganglioside, Oligos, Glycolipids	HEXA
Gangliosidosis GM2, Sandhoff	$\beta$ -Hexosaminidase A + B	GM2 ganglioside, Oligos,	HEXAB
Gaucher (Types I, II, III)	Glucosylceramidase	Glucosylceramide	GBA
Krabbe	$\beta$ -Galactosylceramidase	Galactosylceramide	GALC
Metachromatic leucodystrophy	Arylsulfatase A	Sulfatides	ARSA
Niemann-Pick (Types A, B)	Sphingomyelinase	Sphingomyelin	SMPDI
<i>Oligosaccharidoses (glycoproteinoses)</i>			
Aspartylglucosaminuria	Glycosylasparaginase	Aspartylglucosamine	AGA
Fucosidosis	$\alpha$ -Fucosidase	Glycoproteins, glycolipids, Fucose-rich oligos	FUCA1
$\alpha$ -Mannosidosis	$\alpha$ -Mannosidase	Mannose-rich oligos	MAN2B1
$\beta$ -Mannosidosis	$\beta$ -Mannosidase	Man (b $\rightarrow$ 4) G1nNAc	MANBA
Schindler	N-acetylgalactosaminidase	Sialylated/asialoglycopeptides, glycolipids	NAGA
Sialidosis	Neuraminidase	Oligos, glycopeptides	NEUI

<i>Disease</i>	<i>Defective protein</i>	<i>Main storage materials</i>	<i>Gene involved</i>
<i>Glycogenoses</i>			
Glycogenosis II/Pompe	$\alpha$ 1, 4-glucosidase (acid maltase)	Glycogen	GAA
<i>Lipidoses</i>			
Wolman/CESD	Acid lipase	Cholesterol esters	LIPA
<i>Non-enzymatic lysosomal protein defect</i>			
Gangliosidosis GM2, activator defect	GM2 activator protein	GM2 ganglioside, oligos	GM2A
Metachromatic leucodystrophy	Saposin B	Sulfatides	PSAP
Krabbe	Saposin A	Galactosylceramide	PSAP
Gaucher	Saposin C	Glucosylceramide	PSAP
<i>Transmembrane protein defect</i>			
<i>Transporters</i>			
Sialic acid storage disease; infantile form (ISSD) and adult form (Salla)	Sialin	Sialic acid	SLC17A5
Cystinosis	Cystinosin	Cystine	CTNS
Niemann-Pick Type C1	Niemann-Pick type 1 (NPC1)	Cholesterol and sphingolipids	NPC1
Niemann-Pick, Type C2	Niemann-Pick type 2 (NPC2)	Cholesterol and sphingolipids	NPC2
<i>Structural Proteins</i>			
Danon	Lysosome-associated membrane protein 2	Cytoplasmatic debris and glycogen	LAMP2
Mucopolidosis IV	Mucolipin	Lipids	MCOLN1
<i>Lysosomal enzyme protection defect</i>			
Galactosialidosis	Protective protein cathepsin A (PPCA)	Sialyloligosaccharides	CTSA
<i>Post-translational processing defect</i>			
Multiple sulfatase deficiency	Multiple sulfatase	Sulfatides, glycolipids, GAGs	SUMF1
<i>Trafficking defect in lysosomal enzymes</i>			
Mucopolidosis IIa/b, III a/b	GlcNAc-1-P transferase	Oligos, GAGs, lipids	GNPTAB
Mucopolidosis IIIg	GlcNAc-1-P transferase	Oligos, GAGs, lipids	GNPTG
<i>Polypeptide degradation defect</i>			
Pycnodysostosis	Cathepsin K	Bone proteins	CTSK
<i>Neuronal ceroidlipofuscinoses (NCLs)</i>			
NCL 1	Palmitoyl protein thioesterase (PPT1)	Saposins A and D	PPT1
NCL 2	Tripeptidyl peptidase 1 (TPP1)	Subunit c of ATP synthase	TPP1
NCL 3	CLN3, lysosomal transmembrane protein	Subunit c of ATP synthase	CLN3
NCL 5	CLN5, soluble lysosomal protein	Subunit c of ATP synthase	CLN5
NCL 6	CLN6, transmembrane protein of ER	Subunit c of ATP synthase	CLN6
NCL 7	CLC7, lysosomal chloride channel	Subunit c of ATP synthase	MFSD8
NCL 8	CLN8, transmembrane protein of endoplasmic reticulum	Subunit c of ATP synthase	CLN8
NCL 10	Cathepsin D	Saposins A and D	CTSD

Modified from Filocamo and Marrone Human Genomics, 2011.

involvement lead to tremendous clinical variability, even within a single disease. The disease tends to be progressive, as more waste substrate accumulates over time and more secondary pathology evolves. Early recognition of presenting symptoms and timely diagnosis are essential and require good cooperation between medical specialists. If diagnosed late and/or left untreated, patients are at risk of developing significant, irreversible damage and loss of body functions, and life-threatening complications.

The CNS seems to be particularly vulnerable to LSDs: most of these disorders manifest with neurological signs, and in some LSDs, the brain and/or peripheral nervous system is the sole affected organ, such as in Tay-Sachs disease or metachromatic leukodystrophy, respectively. A single clinically defined disorder may be caused by more than one enzymatic defect, such as Sanfilippo disease (MPS III), which can be caused by a deficiency in any one of four hydrolases. Conversely, a disorder caused by a single enzyme deficiency usually gives rise to a spectrum of manifestations depending on the amount of residual enzyme activity and currently unknown modifiers.

Specific mutations can be associated with certain outcomes, such as in Gaucher or Pompe disease patients. In other disorders there is no clear-cut genotype-phenotype correlation. Patients with the same mutation may present in childhood or be asymptomatic throughout adult life. For women with X-linked LSDs, such as Fabry disease, the severity and extent of disease manifestations may be determined primarily by the degree of X-chromosomal inactivation, although evidence of random inactivation has been shown.

Our understanding of pathogenesis has progressed greatly due to the availability of a large number of animal models for these disorders. These mutants arise either spontaneously (as, for example, in domestic cats, dogs, sheep, cattle), or are engineered. These animal models have played an important role in the development of therapies for specific conditions.

## CLINICAL FEATURES

The signs and symptoms of LSDs vary depending on disease type and other factors such as age at onset. Some LSDs are evident at birth, such as  $\beta$ -glucuronidase deficiency, or are diagnosed at 2–6 months of age, such as in infantile GM1-gangliosidosis, Krabbe disease or Tay-Sachs disease. Other LSDs, such as metachromatic leukodystrophy (MLD), become symptomatic in late infancy or childhood, as with some of the MPSs. Although many LSDs present in childhood, some manifest during the second decade or adulthood, as exemplified by adult GM2-gangliosidosis.

Symptoms of LSDs include failure to reach developmental milestones, visual disturbances, organomegaly (most notable in Gaucher and Niemann-Pick disease), hypersplenism and anemia, dysmorphic features and bony disease (which typify MPSs), seizures and neuromotor regression. Some of the late-onset (adult) forms have psychiatric manifestations of depression or psychosis in addition to neurological deficits, as seen in adult forms of MLD and adult GM2-gangliosidosis. The neurological and other complications that ensue over time in LSDs cause substantial morbidity and diminished quality of life for patients and their families, with death occurring in early life in most cases.

## DIAGNOSIS

Although the first clinical descriptions of patients with LSDs were reported at the end of the 19th century by Warren Tay (1881) and Bernard Sachs (1887)—Tay-Sachs disease, and by Philippe Gaucher in 1882 (Gaucher disease), the biochemical nature of the accumulated products was only elucidated some 50 years later (1934). Considerably more time was then required for the

demonstration by Hers (1963) that there was a link between an enzyme deficiency and a storage disorder (Pompe disease). In the following years, the elucidation of several enzyme defects led to the initial classification of the various types of LSDs according to their clinical pictures, pathological manifestations and the biochemical nature of the undegraded substrates.

**Flow chart 1** presents an algorithm for diagnosis of LSDs with dysmorphic facies, organomegaly, or multiplex dysostosis. A thorough physical examination is essential. Presence of organomegaly or coarse facial features or corneal clouding should be carefully looked for, as they provide important clues for establishing the diagnosis. Fundus examination is very useful because the presence of retinal changes or cherry red spot narrows down the possibilities. A careful neurologic examination is indispensable. In the presence of neurologic abnormalities, obtaining an MRI study with MRS is quite helpful. The relevant changes are discussed in the appropriate sections.

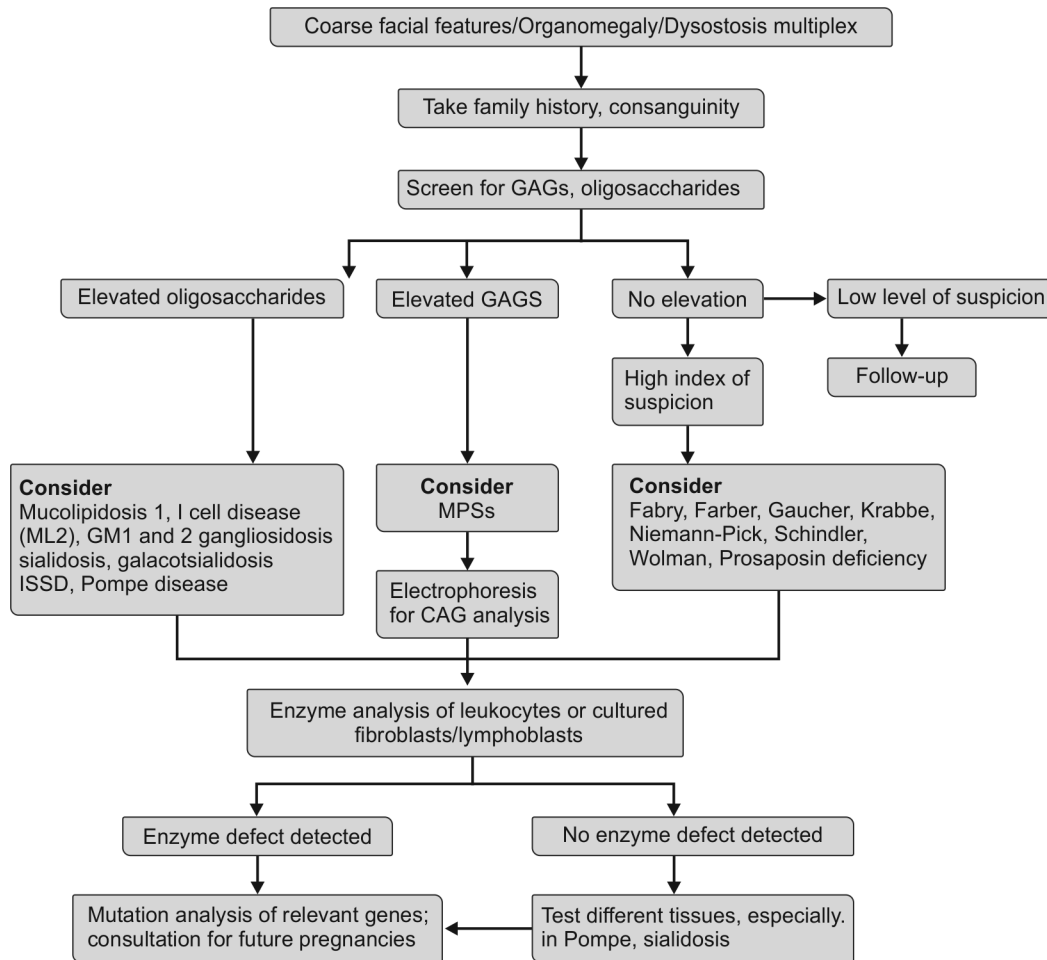

Neuronal ceroid lipofuscinosis (NCL) disorders have recently been added to group of LSDs. Most childhood subtypes of NCL are characterized by a combination of cognitive and motor decline, loss of vision, seizures and early death. In general, the NCLs are pathologically characterized by storage of autofluorescent material (including protein subunit C of mitochondrial ATP synthase or saposins) within neuronal lysosomes. The various NCLs are characterized by electron-dense ultrastructural features that are unique to each disorder, and the aberrant storage is accompanied by neuronal death and cerebral and/or cerebellar cortical atrophy.

## Laboratory Diagnosis

Once suspected from clinical features, it is useful to carry out some screening tests:

- i. Urine:
  - a. Toluidine blue spot test and excretion of glycosaminoglycans in urine (mg/creatinine) for MPS disorders.
  - b. Urine oligosaccharide excretion patterns for diagnosis of oligosaccharidoses.
  - c. Assessment of urinary sulfatide storage, increased in MLD (due to arylsulfatase A enzyme deficiency or saposin B activator defect);
  - d. Urinary excretion of free sialic acid is increased in sialic acid storage disorders [the severe infantile form (ISSD) or the slowly progressive adult form (Salla)].
- ii. Serum levels of metabolites/proteins:
  - a. Serum creatine kinase (CK) concentrations, elevated in Pompe disease;
  - b. Chitotriosidase is raised in Gaucher disease and, to a lesser extent, in other lipidoses.

These preliminary tests may be false positive or negative, and, therefore, specific enzymatic assay or molecular analyses should be performed if there is strong clinical suspicion.
- iii. Many LSDs are due to a *deficiency in lysosomal hydrolase activity*; therefore, the specific enzyme assay should be performed for reliable diagnosis. The enzyme can be measured in leukocytes, serum and fibroblasts. Measurement in the fibroblasts is the gold standard, although most often measuring in leukocytes suffices. Recently measuring the enzyme in blood collected on filter paper (DBS, dried blood spot), has gained importance, as the enzyme stays stable and the sample is easy to collect and transport.
- iv. In affected subjects, the enzyme activity is less than 5% of mean normal, while in Gaucher disease the cut off is often taken as 10%. In all cases if doubt molecular studies are carried out.
- v. Tandem mass spectrometry is increasingly being applied for the diagnosis of LSDs. The equipment is costly, but a single

**Flow chart 1** Algorithm for diagnosis of lysosomal storage disorders

Modified from Staretz-Chacham, et al. *Pediatrics*. 2009

blood spot can be used to diagnose many LSDs. It is indeed a useful technique, and is also being applied for diagnosis of LSDs in the newborn.

- vi. Molecular analysis and demonstration of the mutation in the specific gene is the definitive test. It also provides genotype-phenotype information, and is useful for genetic counseling, carrier screening and prenatal diagnosis.
- vii. Some individuals show greatly reduced enzyme activity but remain clinically healthy. This condition is called enzymatic *pseudodeficiency* (PD). It has been identified in at least nine lysosomal enzymes, including: arylsulphatase A (ARSA gene),  $\beta$ -hexosaminidase (HEXA gene),  $\alpha$ -iduronidase (IDUA gene),  $\alpha$ -glucosidase (GAA gene),  $\alpha$ -galactosidase (GLA gene),  $\beta$ -galactosidase (GLB1 gene),  $\alpha$ -fucosidase (FUCA1 gene) and  $\beta$ -glucuronidase (GUSB gene). The most common among these is the arylsulphatase A (ASA) pseudodeficiency which has a frequency of 7.3–15 %. Subjects with neurological symptoms and homozygous for arylsulphatase A Pd are likely to be misdiagnosed as MLD. It is, therefore, necessary to perform a combination of enzymatic and molecular analyses to determine the actual genetic make-up of MLD patients and their family members, in order to distinguish individuals carrying Pd alleles from those carrying MLD alleles.

#### Activator Proteins

Another complication that can potentially lead to missed diagnoses is represented by defects of cofactors required for the function

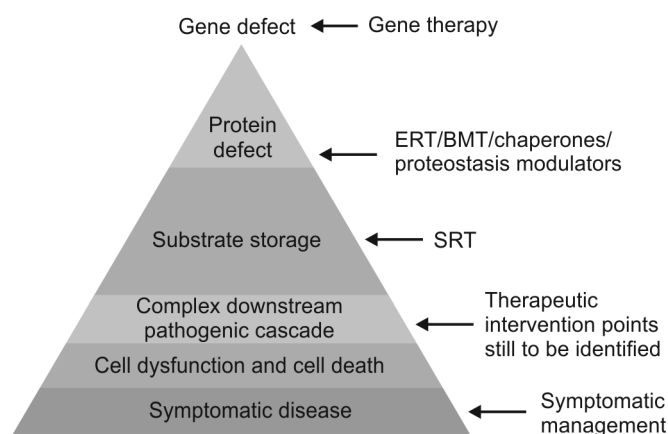

of certain lysosomal enzymes involved in glycosphingolipid breakdown. Variant forms of GM2 gangliosidosis, Krabbe disease, MLD and Gaucher disease can result not only from a deficiency of an enzymatic activity, but also from defects of sphingolipid activator proteins or saposins. In these cases, conclusive diagnosis requires a comprehensive evaluation based on neuroradiological, neurophysiological, biochemical/enzymatic and molecular tests. Conversely, if affected subjects with a clinical/paraclinical picture resembling some glycosphingolipidoses show normal activity of the relevant lysosomal enzyme, they should be evaluated for a defect of an activator protein.

#### TREATMENT

Lysosomal storage disorders require a multidisciplinary, team approach to treatment. Comprehensive management generally combines disease-specific therapy with symptom-specific measures. Apart from enzyme replacement therapy taking care of nutrition, and administering iron and vitamin D, and correcting other deficiencies improves the outlook. Orthopedic and neurologic advice should be available. There have been significant advances in therapy for LSDs in the past two decades. These are depicted in **Figure 4**. Details are provided in the section on respective disorders.

#### Enzyme Replacement Therapy (ERT)

This is the single most significant therapeutic advance. The critical element for success of ERT was the recognition that the

**Figure 4** The pyramid of therapy for LSDs  
Adapted from Platt, *Nature* 2014.

enzymes use a mannose-6-phosphate receptor to enter into the macrophages. ERT was first developed for type 1 Gaucher disease. Initially, the therapeutic enzyme was derived from placental tissue, but subsequently it has been manufactured by recombinant DNA technology. Later on, ERT was developed for Fabry disease, Pompe disease, MPS 1, MPS 2, and for MPS VI. Clinical trials are ongoing for enzyme therapies for  $\alpha$ -mannosidosis, Wolman cholesteryl storage disease, Morquio syndrome (MPS IV A) and Niemann-Pick disease B. ERT is usually given to the patients by intravenous route every week or every 2 weeks. ERT has changed the life of many individuals with LSDs, especially where there is no neurologic involvement.

Important challenges to ERT remain: (i) Production of antibodies to the administered enzyme. Many patients do not produce native enzyme (CRIM negative and cross-reacting immunologic material negative); or make native enzyme that differs significantly from administered enzyme, and consequently make antibodies to the exogenous enzyme, which may reduce efficacy and often causes adverse infusion reactions; (ii) ERT has to be given lifelong, and the cost is prohibitive. Thus, only a few patients have access to ERT. In most countries, the Government or the insurance companies cover the cost, but this is a great limitation for use of ERT in developing countries; (iii) The lysosomal enzymes do not cross the blood-brain barrier, so these cannot be used in the presence of significant brain disease.

### Bone Marrow Stem Cell Transplantation

Bone marrow transplantation (BMT) from healthy HLA-matched donors has been used for therapy in Gaucher disease, and other LSDs in the presence of neurologic involvement. In the latter instance, to be effective, it has to be carried out in early stage of the disease before severe neurologic disease has set it in. After BMT, some donor-derived monocytes enter the CNS and serve as local sites of normal enzyme production, which can be taken up by nearby host cells. BMT has been successful in cases of MPS1, provided it is performed before 2 years of age.

### Substrate Reduction Therapy

Substrate reduction therapy (SRT) with oral small molecule miglustat (imino sugar drug) has been used for treating LSDs. Miglustat inhibits the Golgi enzyme, glucosylceramide, and it reduces the synthesis of glycosphingolipids, thereby reducing

substrate requiring lysosomal catabolism and reducing storage. This drug is approved for type 1 Gaucher disease. Miglustat also crosses the blood-brain barrier, hence, it proved useful in treating Niemann-Pick type C disease. Its primary side effect is the development of gastrointestinal symptoms, due to the inhibition of disaccharidases. The more recent molecule to be approved in this category, eliglustat tartrate, has shown good effect in the treatment of type 1 Gaucher disease as an oral substrate reduction therapy. It has also proved beneficial in bone disease in Gaucher disease. However, it does not cross blood brain barrier. Preliminary studies have shown this to be as effective as ERT, and the future therapy with this drug will be watched with great interest. However, for SRT to reduce lysosomal storage, there must be residual enzyme activity, which is always the case in GD but not in other disorders.

### Gene Therapy

The only cure for any single gene disorder is gene therapy. LSDs are attractive candidates for gene therapy because lysosomal enzymes are secreted and recaptured by neighboring cells so that not every cell needs transducing. However, so far, this form of therapy has not yet reached routine clinical practice. Proof-of-concept studies have shown efficacy in animal disease models. Gene therapy would have to be given early before irreversible CNS pathology has occurred. It would have to be given intravenously to correct both peripheral tissues and the CNS, and the body organs. However, many hurdles must be overcome before gene therapy can be applied to the LSDs including delivery to the correct cells, random integration, sustained expression and immune reactions.

### Chaperon Therapy

Oral small molecule chaperones are compounds that improve the folding and trafficking of lysosomal proteins with specific missense mutations. Folding allows to bypass the endoplasmic reticulum (ER) quality-control system, and enhances their trafficking to Golgi and lysosomes, which ultimately raises residual enzyme activity. Clinical trials for Fabry disease are underway. Ataluren causes the ribosome to read through nonsense codons and yet allows the ribosome to end translation normally at the correct stop codon. This drug currently is being tested in other disorders and could be useful for some patients with LSDs caused by nonsense mutations.

## PREVENTION

### Genetic Counseling and Prenatal Diagnosis

In developing countries, counseling regarding mode of inheritance and risk of recurrence is important, so that the parents can opt for prenatal diagnosis in future pregnancies in order to avoid having another affected child, so as to reduce the burden of the disease.

### Newborn Screening

This is being done in LSDs as, for therapy to be effective, it has to be given early before irreversible changes have occurred. This is especially important for classical Pompe disease that manifests with cardiomegaly in infancy. Many patients with LSD remain undiagnosed till a later age, so that a second affected child is often born before the first is diagnosed. Newborn screening also provides information regarding the incidence of the disorder in the population, which is so critical for public health approach to the problem of LSDs.

### IN A NUTSHELL

1. Storage disorders are complex groups of disorders with heterogeneous clinical and biochemical features.
2. Most present chronically with multisystem involvement and pediatricians are likely to come across these cases in clinical practice.
3. In most disorders, diagnosis is made by enzyme assays but it is preferable to confirm the diagnosis by mutation testing.
4. Most are inherited in autosomal recessive manner and prenatal diagnosis is possible.
5. Promising and proven therapies are already in clinical use for some LSDs and more are likely to be available in the near future.

## Chapter 3.9

# GM1 and GM2 Gangliosidosis

Parag M Tamhankar

Gangliosidosis are a group of autosomal recessive genetic disorders caused by accumulation of substances known as ganglioside. These include Tay-Sachs disease, Sandhoff disease, GM2 activator deficiency and GM1 gangliosidosis caused by mutations in *HEXA*, *HEXB*, *GM2A* and *GLB1* genes, respectively. The first three genes are necessary for normal catabolism of GM2 ganglioside and the *GLB1* is important for catabolism of GM1 ganglioside. These disorders are characterized by progressive neurological deterioration with early childhood forms proving fatal. These diseases have been naturally found in animals.

## EPIDEMIOLOGY

Gangliosidoses are panethnic diseases. However, incidence varies in different population groups. Tay-Sachs disease is the most frequent disorder in this group with founder mutations accounting for high incidence in communities or geographic regions with high inbreeding. Before community-based screening programs, 1 per 2,500–3,500 newborns in the Ashkenazi Jews was affected. In the general population, the carrier rate is estimated to be 1/258. The incidence of Sandhoff disease is approximately 1 per 3,10,000 non-Jewish newborns and 1 per 1 million Jewish newborns. The incidence of GM1 gangliosidosis is estimated to be 1:100,000–1:200,000 livebirths. High prevalence has been found in Malta and Brazil, and in the Cypriot and Roma populations.

## ETIOPATHOGENESIS

A ganglioside is a molecule composed of glycosphingolipid (ceramide and oligosaccharide) with one or more sialic acids (e.g., N-acetyl neuraminic acid) linked on the sugar chain. They are predominantly found in the nervous system where they constitute 6% of the phospholipids. They are present on cell surface, with the oligosaccharide groups projecting into extracellular space. They are thought to be involved in neuritogenesis, synaptogenesis, neuronal differentiation and regeneration, cell-to-cell interactions and to act as receptors for certain hormones and bacterial toxins. The gangliosides are stepwise degraded in the lysosomes from GM1 to GM3 into ceramides by sequential removal of sugar units in the oligosaccharide group. Glycohydrolases such as  $\beta$ -galactosidase (GM1-GM2 breakdown) and hexosaminidase (Hex) A (GM2-GM3 breakdown) are needed. Deficiency of  $\beta$ -galactosidase which removes the terminal galactose leads to GM1 gangliosidosis. The hydrolysis of GM2-ganglioside requires three gene products. Whereas two of these are the  $\alpha$ -(*HEXA*) gene and  $\beta$ -(*HEXB*) subunits of  $\beta$ -hexosaminidase A, the third is a small glycolipid transport protein, the GM2 activator protein (GM2A), which acts as a substrate-specific cofactor for the enzyme. A deficiency of any one of these proteins leads to one of the three forms of GM2-gangliosidosis, Tay-Sachs disease, Sandhoff disease or the AB-variant form.

Neuropathological features observed include widespread neuronal degeneration characterized by varying degrees of swelling, cytoplasmic vacuolation, loss of Nissl bodies and margination of nuclei. The accumulated ganglioside stains Periodic acid-Schiff positive. The exact mechanisms that translate the accumulation of gangliosides in neuronal cells to cell death are yet to be determined. One hypothesis links the activation of inflammatory pathway by the accumulating lipids leading to microglial and astrocyte activation, neuronal cell death and reactive gliosis.

## CLINICAL FEATURES

Gangliosidoses can be clinically classified as per age of onset of symptoms; type I: classical acute forms (infantile), type II: subacute (late infantile and juvenile forms) and type III: chronic forms (adult onset).

Children with *acute form* are usually normal until 3–6 months of age, at which time motor weakness, hypotonia, poor head control and decreasing attentiveness begin to cause parental concern. One of the earliest universal signs noticed by parents in infantile Tay-Sachs disease includes an exaggerated startle reaction to sharp (not necessarily loud) sounds, characterized by blinking of eyes, sudden extension of head, with or without extension of arms and legs. This sign is less frequent in other gangliosidoses. *Cherry red spot* sign is seen on ophthalmoscopy usually by 6 months of age. The sign is produced due to macular pallor due to deposition of gangliosides in the ganglion cell layer, while the normal foveal pit which lacks ganglion cells, continues to retain its reddish appearance. By the end of first year, motor skills previously developed are completely lost. By 18 months, signs of lower and upper motor neuron involvement are evident. Progressive enlargement of head is a result of reactive gliosis. Seizures become more frequent. In the second year, further deterioration affects the swallowing and gag reflexes, necessitating tube feeding. Frequent bronchopneumonia may result and is usually antecedent to death.

Infantile GM1 gangliosidoses and Sandhoff disease may have hepatosplenomegaly, skeletal involvement in form of dysostosis multiplex and extensive and unusually persistent skin Mongolian spots as differentiating features from Tay-Sachs disease. GM1 gangliosidoses cases also have coarse facies, gum hypertrophy and corneal clouding. Angiokeratomas and cardiomyopathy (dilated or hypertrophic) can also occur in infantile GM1 gangliosidoses. **Figures 1A to G** show a 9-month-old child with GM1 gangliosidosis.

Subacute forms present around 2–6 years of age with motor ataxia. Neuroregression may lead to death at around 10–15 years of age. Adult forms can present from 3 years to 30 years of age with abnormalities of gait and posture. Symptoms of spinocerebellar ataxia and lower motor neuron dysfunction, such as weakness, wasting, cramps and fasciculations predominate. Movement disorders, such as dystonia and dyskinesia occur in 50% of all patients. Ocular findings include saccade abnormalities and gaze palsy. Schizophrenic symptoms with slow personality disintegration and episodic depression are present in one-third of patients. Patients usually survive into their third to fourth decade of life. As compared to the acute forms, cherry red spots are infrequent in juvenile forms and rare in adult forms of the disease. Clinical variability even within the same family is significant. They may be misdiagnosed as spinal muscular atrophy, or atypical Friedreich ataxia.

## Differential Diagnoses

Cherry red spots can occur in Niemann-Pick disease types A, B and C, sialidosis type I and II, mannosidosis, Farber lipogranulomatosis, central retinal artery occlusion and retinal edema secondary to trauma.

## INVESTIGATIONS

### Neuroimaging

Findings in gangliosidoses include thalamic lesions that are bilateral, diffuse hypointense on T2-weighted and fluid-attenuated inversion recovery (FLAIR) MRI images and hyperintense on T1-weighted images. Magnetic resonance spectroscopy may reveal decreased N-acetyl aspartate peak through deep gray matter structures suggestive of neuronal loss or dysfunction. White matter changes may occur late in disease as a result of secondary

**Figures 1A to G** (A) A 9-month-old child with GM1 gangliosidosis with mild coarsening of facial features, abdominal distension due to liver, spleen enlargement; (B and C) Extensive Mongolian spots; (D) Dysostosis multiplex including enlarged sella turcica; (E) Oar-shaped ribs; (F) Ovoid vertebral bodies; (G) Broad, proximally pointed bones of the hand. This child had absent  $\beta$ -galactosidase enzyme activity in leukocytes

demyelination following cortical neuronal death and axonal deterioration. They are demonstrated as homogenous or patchy T2 hyperintensity within frontal, temporal, occipital regions and periventricular white matter. Proton magnetic resonance spectroscopy may reveal progressive elevation in myoinositol : creatine ratios within white matter, gray matter and the thalamus. This signifies increased glial cell proliferation.

### Biochemical Diagnosis

This is based upon result of lysosomal enzyme assays, such as beta galactosidase assay for GM1 gangliosidosis and Hex assays for GM2 gangliosidoses. These assays are based on the hydrolysis of synthetic substrates releasing 4-methylumbelliferone producing fluorescence that can be measured. These assays can be performed on leukocytes, serum, plasma, cultured fibroblasts, amniocytes or chorion villus samples.

GM2 gangliosidoses are diagnosed using Hex assays. There are two major Hex isozymes in normal human tissue. Hex A is a heterodimer, alpha-beta, whereas Hex B is a homodimer, beta-beta. Tay-Sachs disease patients have decreased Hex A activity and normal or elevated Hex B activity. Sandhoff patients have decrease in both Hex A and Hex B activities, whereas GM2 activator deficiency patients will have normal Hex A and Hex B activities. Activities found for acute, subacute and chronic patients were  $\leq 0.1\%$ ,  $0.5\text{--}1\%$ , and  $1\text{--}4\%$  of normal controls, respectively.

Although reasonably accurate, the biochemical assays have limitations. As many as 10% of samples can lie in an indeterminate zone range in which carriers and noncarriers overlap. The calculated percentage of hex A is falsely reduced leading to being labeled as a carrier. This can be avoided using leukocyte (which does not contain HEX P) hex assay instead of serum/plasma. In about one-third of non-Jewish population, the enzyme levels may be falsely deficient in normal individuals. Pseudodeficiency is a phenomenon in which normal individuals may be detected as having enzyme deficiency due to failure to lyse artificial substrate but normal in vivo hex activity.

### DNA-based Tests

These can confirm the clinical and biochemical diagnosis. *GLB1* gene (3p22.3), *HEXA* gene (15q24.1), *HEXB* gene (5q13.3) and *GM2A* (5q33.1) are the only genes associated with GM1 gangliosidosis, Tay-Sachs disease, Sandhoff disease and GM2 activator deficiency, respectively. Polymerase chain reaction based techniques such as amplification refractory mutation screen, dot-blot hybridization, etc. for common mutations and Sanger sequencing covering all exons and exon-intron boundaries for identifying uncommon or novel mutations are employed. Southern blot or multiplex ligation-dependent probe amplification techniques are used to identify unknown large deletions or duplications that cannot be identified by Sanger sequencing. The frequency of mutations varies according to populations. In India, a founder mutation E462V was identified in infantile Tay-Sachs disease patients from Gujarat. Most SD mutant alleles are nonrecurrent. Exceptions include R284X, a panethnic mutation hotspot in *HEXB* gene and *c.445+1G>A*, a founder mutation in SD patients from Cordoba, Argentina.

### MANAGEMENT

At present, only symptomatic treatments are available for GM1 and GM2 gangliosidosis. Bone marrow replacement has been used in animal models and individual patients but has achieved mixed results. Enzyme replacement therapies are not applicable to gangliosidoses because of inability to penetrate the blood-brain barrier. Miglustat is a reversible inhibitor of glucosylceramide synthase, the enzyme that catalyzes the first committed step in the synthesis of lacto- and globo-series glycolipids. Miglustat [N-butyldeoxynojirimycin (NB-DNJ)] is licensed for the treatment of adult patients with mild-to-moderate type 1 Gaucher disease for whom enzyme replacement therapy is unsuitable or not a therapeutic option. It has specific physicochemical properties that facilitate wide tissue distribution, including the brain. In vivo studies have demonstrated the ability of miglustat to prevent storage of GM2 ganglioside in the peripheral tissues and central

nervous system of mouse models of TSD and Sandhoff disease. Miglustat has also been used for chronic GM2 gangliosidosis type Sandhoff.

A growing body of evidence suggests that misfolding of a mutant protein followed by its aggregation or premature degradation in the endoplasmic reticulum is one of the main mechanisms that underlie inherited neurodegenerative diseases, including lysosomal storage diseases. Chemical or pharmacological chaperones are substrate analog competitive inhibitors bind to and paradoxically stabilize mutant lysosomal enzyme proteins in the endoplasmic reticulum, enter the lysosome and restore catalytic activity of mutant enzyme after spontaneous dissociation under acidic conditions. A number of chaperone compounds for lysosomal hydrolases have been identified in the last decade. They have gained attention because they can be orally administered, and also because they can penetrate the blood-brain barrier. Several chemical chaperones investigated in vitro include galactose, fluorouracil, iminoalcohols and valienamine derivatives, N-octyl-4-epi- $\beta$ -valienamine and N-octyl- $\beta$ -valienamine in GM1 gangliosidosis, pyrimethamine in Sandhoff disease.

## PROGNOSIS

The infantile and juvenile cases are relentlessly progressive, leading to early death. Chronic or adult cases also have reduced life expectancy but may have improved survival with good supportive care.

## PREVENTION

Gangliosidoses are autosomal recessively inherited genetic disease. The recurrence risk in progeny of carrier couples is 25%. Prenatal diagnosis is possible by performing enzyme assays or DNA tests on fetus but prerequisites include biochemical and/or molecular confirmation in the carrier couple. Carrier diagnosis can be performed using leukocyte enzyme assays (70% sensitive) and molecular assays (99%). Primary prevention of Tay-Sachs disease has been demonstrated by community screening in high-risk populations.

## IN A NUTSHELL

1. Gangliosidoses are characterized by cherry red spot, progressive neurological regression, liver/spleen enlargement (GM1 and storage diseases), and skeletal dysostoses (GM1).
2. Lysosomal enzyme assays employing artificial substrates [4-methylumbelliferyl N-acetylglucosamine (MUG, MUGS)] can diagnose these disorders with more than 90% sensitivity. Sulfated substrate (MUGS) is needed to diagnose B1 variant.
3. Advantage of molecular tests over biochemical is the ability to diagnose pseudodeficiency and AB variant (GM1 activator deficiency).
4. Treatment is still in drug designing or preclinical stage.
5. Preventive strategies to reduce incidence are possible by carrier detection and prenatal diagnosis, which remains the focus of management.

## Chapter 3.10

# Gaucher Disease

Mamta Muranjan

Gaucher disease is the most common and one of the most extensively studied lysosomal storage disorder. It is a lifelong multisystemic disease demonstrating marked clinical heterogeneity. It is an autosomal recessive condition that results from mutations of the glucosidase, beta, acid (*GBA1*) gene located on chromosome 1q21. More than 400 mutations of the *GBA1* gene (MIM no. 606463) have been identified to date. The gene codes for the lysosomal membrane-bound protein, the enzyme acid  $\beta$ -glucocerebrosidase (EC 3.2.1.45). Sources of glucocerebroside differ among tissues. In the visceral organs, it is derived from cell membranes of senescent red and white blood cells and platelets that contain glycosphingolipids, whereas the source in the central nervous system (CNS) is gangliosides. Those with non-neuronopathic Gaucher disease have sufficient residual enzyme activity to degrade ganglioside-derived glucosylceramide and, hence, lack substrate accumulation in the brain.

### EPIDEMIOLOGY

Gaucher disease is panethnic with a global prevalence of 1 in 40,000 to 1 in 60,000. The highest frequency of Gaucher disease is amongst Ashkenazi Jews with an incidence of 1 in 855 and a carrier frequency of 1 in 18. In India, Gaucher disease is frequent among the tribal population of Mappila Muslims of Kerala.

The N370S allele accounts for almost 70% of disease alleles in Ashkenazi Jews. This along with four other alleles (L444P, 84insG and IVS2+1G>A and R463C) account for 90% of the mutations. The L444P allele is the most common worldwide. From the limited published data on genotype of Indian patients with Gaucher disease, the L444P mutation is the single most common mutation in 63% while the N370S mutation is rare. Molecular analysis of 58 patients with Gaucher disease, from three centers in India (Center for Human Genetics, Bangalore; KEM Hospital, Mumbai and Amrita Institute of Medical Sciences and Research, Kochi) revealed homozygous L444P genotype in 58%. In Japanese and East Asian patients, the frequency of L444P mutation is 50%, indicating higher proportion of neuronopathic disease.

Geographic and probably ethnic differences in manifestations are also observed. Jewish and European populations have onset of symptoms of type 1 disease in late childhood or adult life. The predominant symptoms are visceral, hematological and skeletal. In contrast, Asian, Chinese and Indian patients have early onset of severe visceral, hematological and neurological symptoms.

### PATHOPHYSIOLOGY

The pathophysiology of Gaucher disease is a complex interplay of several mechanisms which includes infiltration of viscera by storage cells, macrophage activation by glucosylceramide storage, production of deleterious complex glycolipids like glucosyl-sphingosine, perturbed microenvironment, focally compromised microvasculature, dysregulation of calcium homeostasis and misfolding and impaired intracellular trafficking of the mutant protein giving rise to the unfolded protein response which leads to activation of inflammation/apoptosis.

Glucosylceramide accumulates within the macrophages and transforms them into the pathognomonic storage cells—the Gaucher cell (**Fig. 1**). This is a large uninucleate or multinucleate cell measuring 20–100  $\mu$ m in diameter. The nucleus is small, round

**Figure 1** Gaucher cells (arrow) in the bone marrow

or oval and eccentric and the cytoplasm is abundant, staining pale pink with hematoxylin and eosin with delicate striations producing *crumpled silk* or *wrinkled tissue paper* appearance. The storage material stains positive with periodic acid-Schiff. The Gaucher cells infiltrate the bone marrow medullary cavity, liver, spleen, lungs, lymph nodes and rarely the kidney. In contrast, the pathology in the CNS is neuronal death.

### CLINICAL MANIFESTATIONS

Traditionally, the clinical phenotypes of Gaucher disease were classified into three major groups based on the presence and severity of neurological symptoms. Absence of neurological involvement was characteristic of type 1 disease. Type 2 disease (formerly acute neuronopathic variant) has an onset of severe neurological symptoms in early infancy and death by 2 years of age, whereas type 3 disease (formerly chronic neuronopathic variant also known as the Norrbottnian type after the description in the Norrbotten region in North Sweden) had a variable age of onset of neurological symptoms, rate of progression and life span. The incidence, distinguishing clinical features and life span of the three major phenotypes are presented in **Table 1**.

Recent insights have expanded the knowledge of clinical variants of Gaucher disease, which is now considered to have an overlapping clinical spectrum (**Fig. 2**) ranging from asymptomatic individuals or delayed onset of symptoms in the eighth or ninth decades of life to severe perinatal/lethal variant of type 2 disease with in utero manifestations. Presymptomatic children may be diagnosed through newborn screening or because of an affected sibling with Gaucher disease. Research has also revealed an increased frequency of late onset parkinsonism in homozygous individuals with type 1 Gaucher disease and in heterozygous carriers. Brain pathology has shown astrogliosis, abnormalities in the hippocampal regions and  $\alpha$ -synuclein reactive Lewy bodies in the brain of individuals with Gaucher disease and parkinsonism.

Study of mutations in Gaucher disease has revealed a phenotype-genotype correlation. The N370S mutation in homozygous or heterozygous state confers protection from neurological disease, whereas the L444P mutation predicts neurological disease. In type 2 disease, the L444P mutation occurs in heterozygous state with null or recombinant complex mutations, whereas L444P mutation in the homozygous state predicts type 3 disease. Those homozygous for the N370S mutation have significant skeletal disease while typical symptoms like splenomegaly, hepatomegaly, anemia and thrombocytopenia are mild. The compound

Source: Adapted from figure available at [http://www.physio-pedia.com/index.php?title=Gaucher\\_Disease&oldid=35158](http://www.physio-pedia.com/index.php?title=Gaucher_Disease&oldid=35158).

**Table 1** Distinguishing features of the three phenotypic variants of Gaucher disease

Phenotypic variant	Type 1	Type 2	Type 3
<i>Prevalence</i>			
Worldwide	1 in 50,000 to 1 in 100,000	1 in 500,000	<1 in 50,000 to <1 in 100,000
Ashkenazi Jews	1 in 850		
Frequency (%)*	94	1	5
Age at onset of symptoms	Any age	<2 years of age	<2 years of age
Life span	6 to >80 years	2–4 years of age	3rd–4th decade
Hepatosplenomegaly	Mild to severe	Moderate	Mild to severe
Hematologic abnormalities	Mild to severe	Severe	Mild to severe
Bone disease	Mild to severe	Very rare	Absent to severe
Neurological symptoms	Absent (exception: parkinsonism and secondary neurologic involvement)	Severe (bulbar and pyramidal signs, cognitive impairment)	Mild to severe (seizures, myoclonic epilepsy, oculomotor apraxia)

\*Data from the International Collaborative Gaucher Group

heterozygous genotype of N370S/L444P results in severe type 1 disease. A cardiac variant of type 3 Gaucher disease is associated with homozygous D409H mutation.

### NON-NEURONOPATHIC (TYPE 1) GAUCHER DISEASE

Type 1, formerly classified as adult-onset Gaucher disease, accounts for 94% of all individuals with Gaucher disease. However, 55–60% of these individuals are detected before 20 years of age and 30% before 10 years of age. The younger the age at presentation, the

more rapid the disease progression and greater is the severity in terms of hematological and visceral symptoms and bone disease.

### Visceral Involvement: Splenomegaly and Hepatomegaly

More than 80% of children have enlarged liver and spleen at the time of diagnosis. Moderate to severe splenomegaly is noted in 95% and 87% have moderate to severe hepatomegaly. Splenomegaly is an almost consistent feature. Absence of splenomegaly, though unusual, does not exclude the diagnosis of Gaucher disease. It can be seen in older adults with N370S/N370S genotype.

Symptoms of splenic enlargement are abdominal distension, early satiety and dragging pain in the left hypochondrium. The spleen can enlarge more than five times the normal and median spleen volumes exceeding 20 times the normal have been observed (**Fig. 3**). The resultant hypersplenism causes pancytopenia and

**Figure 3** Abdominal CT scan of a 39-month-old showing massive splenomegaly reaching up to the pelvis with heterogenous appearance suggestive of infiltration due to Gaucher disease. There are subcapsular hypodense areas (arrows) representing multiple infarcts. The liver also shows diffuse infiltration

**Figures 4A and B** Hepatopulmonary syndrome in a 10-year-old boy with type 1 Gaucher disease, who had undergone splenectomy at 3 years of age followed by bone crisis. (A) Massive abdominal distension with a horizontal surgical scar below the left costal margin; (B) Dilated and tortuous veins over the anterior abdomen wall indicating presence of portal hypertension. He died at 10 years of age following an acute intracranial hemorrhage

aggravates anemia and thrombocytopenia. Focal defects in the spleen are known to occur in 20% of cases and are attributed to focal infiltration by Gaucher cells or infarcts. Infarcts manifest with acute abdominal pain. Rupture of the spleen is rare.

Earlier, splenectomy was performed for massive symptomatic splenomegaly (**Fig. 4A**) but is now obsolete with availability of enzyme replacement therapy. Gaucher disease is sometimes first diagnosed by finding Gaucher cells on histopathological examination of the surgically removed spleens. Splenectomy invariably leads to severe accelerated disease in the liver, lungs and skeleton.

The magnitude of liver enlargement is less as compared to the spleen. Median liver size of more than 2 times the normal have been observed. Hepatic fibrosis, cirrhosis, portal hypertension (**Fig. 4B**) with ascites and esophageal varices and hepatic failure are rare. Manifestations of dyspnea, cyanosis and clubbing would suggest development of hepatopulmonary syndrome.

### Hematological Involvement

Anemia and thrombocytopenia are the hallmarks of Gaucher disease affecting 40% and 50% of children, respectively. Anemia presents with pallor, fatigue and congestive heart failure. Periodic blood transfusions are required, especially when hypersplenism coexists. Iron and vitamin B<sub>12</sub> deficiency are common in India and may contribute to the anemia. Thrombocytopenia would be symptomatic with petechiae, epistaxis, gum bleeds, bruising and bleeding associated with trauma, surgery or menorrhagia. Abnormal platelet aggregation and low-grade disseminated intravascular coagulopathy contribute to bleeding manifestations in Gaucher disease. Other hematological abnormalities include leukopenia and defective neutrophil function. A variety of acquired coagulation factor deficiencies have been described, namely fibrinogen, II, VII, VIII, X and XII.

### Skeletal Involvement

Recognition of bone involvement in Gaucher disease is suboptimal even though it is the most debilitating and disabling manifestation impairing quality of life. Radiologic bone disease is present in 81% of children with Gaucher disease, 27% had bone pain and bone crisis was observed in 9%. Significant bone disease can be asymptomatic

and does not correlate with severity of manifestations in other organs. Complex multifactorial mechanisms initiated by bone marrow infiltration, mediated by cytokines and perpetuated by interactions between osteoblasts/osteoclasts and immunological cells are implicated in the pathogenesis of bone disease. The various skeletal manifestations of Gaucher disease are described in **Table 2**.

Involvement of the skeleton by Gaucher disease is focal, local or generalized. Focal, irreversible pathology includes lytic or sclerotic bone lesions (**Fig. 5A**). Local, reversible disease includes lesions, such as cortical bone thinning, endosteal scalloping (**Fig. 5B**) and defective bone remodeling. Generalized bone involvement is in the form of osteopenia and osteoporosis (**Fig. 5B**). Plain radiographs may show osteopenia, cortical thinning and Erlenmeyer flask deformity of the distal femoral metaphysis in type 1 disease (**Fig. 6**). A manifestation of Gaucher disease unique in children is the impact on growth with suboptimal growth noted in 75% of children with 34–42% falling below the 5th percentile for height (**Fig. 7**). Pubertal delay has been observed in 60%.

Several unusual or atypical manifestations of Gaucher disease are being increasingly reported, contributing to the expanding spectrum. These are enumerated in **Table 3**.

**Figures 5A and B** Plain radiographs of the femur. (A) Osteopenia in the femur; (B) Osteopenia, cortical thinning and periosteal elevation (arrows) due to bone crisis

**Table 2** Skeletal abnormalities in Gaucher disease

<i>Nature of bone involvement</i>	<i>Description</i>	<i>Imaging modality of choice</i>
<i>Asymptomatic</i>		
Bone marrow infiltration	Begins in the lumbar spine, followed by metaphysis and diaphysis of the femur and humerus, epiphyses involved late	MRI
Osteopenia/reduction in BMD	Progressive, occurs at any age and in both genders, seen adjacent to areas of bone marrow infiltration but can be diffuse, contributes to risk of fractures and joint collapse	DEXA
Erlenmeyer flask deformity (Fig. 6)	Defect of remodeling, occurs in 59% of cases, distal femur and proximal tibia commonly affected, diaphyseal narrowing with widening of the metaphyseal end of long bones	Plain radiographs
<i>Symptomatic</i>		
Bone pain	Chronic, dull-aching nature	
Bone crisis/bone infarcts	Acute, prolonged episodes, initially dull aching and then excruciating; involved region is warm, swollen and tender, systemic signs of fever, leukocytosis and elevated erythrocyte sedimentation rate, sterile blood culture, often followed by osteonecrosis or fractures	MRI, plain radiographs may show periosteal elevation (Fig. 5B)
Osteomyelitis	Prone to osteomyelitis due to altered neutrophil chemotaxis or monocyte dysfunction, anaerobic organisms, often precipitated by surgical procedure	Bone scan
Osteonecrosis/avascular necrosis	Splenectomy and male gender are risk factors, medullary or subchondral (head of femur or humerus, proximal tibia and vertebral bodies are common sites, progresses to fracture and/or joint collapse, requires joint replacement surgery)	MRI Plain radiographs show increased bone density with medullary osteonecrosis
Pathologic fractures	Related to osteopenia, bone, infarcts, osteonecrosis and bone crisis	Plain radiographs

Abbreviations: MRI, magnetic resonance imaging; DEXA, dual-energy X-ray absorptiometry; BMD, bone mineral density.

**Figure 6** Plain radiographs showing osteopenia, cortical thinning and Erlenmeyer flask deformity of the distal femoral metaphysis and avascular necrosis of the right upper tibial epiphysis in a 10-year-old with type 1 Gaucher disease

## NEURONOPATHIC (TYPE 2) GAUCHER DISEASE

Typical type 2 disease manifests with hepatosplenomegaly, anemia, thrombocytopenia, oculomotor apraxia, seizures, bulbar signs (strabismus, stridor and dysphagia), and pyramidal signs (trismus, opisthotonus, neck retroflexion and spasticity);

(Figs 8A and B). The perinatal/lethal variant is rare. However, recognition and correct diagnosis are crucial for genetic counseling and prenatal diagnosis in subsequent pregnancies. The spectrum of manifestations includes nonimmune hydrops fetalis, lamellar ichthyosis, collodion membrane at birth, acute neonatal hepatic failure with hyperferritinemia, pulmonary hypoplasia, apnea, respiratory distress, hepatosplenomegaly, pancytopenia, arthrogryposis, facial dysmorphisms (low set ears, flat nasal bridge, anteverted nares and proptosis), microcephaly, poor sucking, stridor and opisthotonus. Death occurs in the first few weeks of life.

## TYPE 3 DISEASE

Type 3 disease progresses slowly. The clinical manifestations are hepatosplenomegaly, anemia, thrombocytopenia, bone and lung disease and variable severity of neurological symptoms. The mildest presentation is with failure of horizontal saccade initiation. Other characteristic neurological symptoms are vertical gaze palsy, slow tracking of objects and convergent squint. It is further classified into three subtypes: Type IIIa (mild visceral involvement but onset of neurodegeneration and severe myoclonic seizures in childhood); type IIIb (mild neurological involvement, horizontal gaze palsy and significant visceral and skeletal symptoms—chest deformity, kyphoscoliosis); (Figs 9A and B) and IIIc (cardiac variant), a distinct phenotype with ophthalmoplegia, calcification of the aortic valve and ascending aorta leading to congestive heart failure and arrhythmias, corneal opacities and hydrocephalus. The Norbottnian variant has mild cognitive impairment, oculomotor defects and progressive gibbus.

**Table 3** Atypical features of Gaucher disease

Pulmonary involvement	Interstitial lung disease, alveolar or lobar consolidation, pulmonary fibrosis, pulmonary hypertension
Kidney involvement	Infiltration of the interstitium and glomeruli, proteinuria, glomerulosclerosis, progressive renal insufficiency
Primary neurologic disease in Gaucher disease type 1	23-fold increased risk of Parkinson disease, positive family history for parkinsonism, typical and atypical parkinsonism, younger age at onset, respond inadequately to L-3,4-dihydroxyphenylalanine (L-DOPA)
Secondary neurologic disease in Gaucher disease type 1	Spinal cord or nerve root compression resulting from vertebral compression due to severe osteopenia, emboli following long bone fracture, or hematomyelia resulting from coagulopathy Peripheral neuropathy
Severe lymphadenopathy	Infiltration of lymph nodes by Gaucher cells mesenteric, retroperitoneal, inguinal and paraesophageal lymph nodes, trapping of intra-abdominal vasculature Persistently high chitotriosidase despite enzyme replacement therapy
Gaucheromas	Mass-like infiltration of Gaucher cells developing in the spleen, liver and bones
Protein-losing enteropathy	Diffuse leakage from intra-abdominal lymphatics due to obstruction
Cholelithiasis	Cholesterol gallstones
Immunologic abnormalities	Gammopathy (monoclonal or polyclonal) Monoclonal gammopathy of undetermined significance (MGUS) Decreased production of NK cells Reduction in number of normal dendritic cells Suboptimum T-cell function or proliferation Compromised IgM secretion
Malignancy	Multiple myeloma Hepatocellular carcinoma Non-Hodgkin's lymphoma Malignant melanoma Pancreatic cancer
Metabolic derangements	High resting energy expenditure Low circulating adiponectin and insulin
Heart	Thickening of aortic and mitral valve due to calcification Intramyocardial infiltration by Gaucher cells causing interstitial infiltrative fibrosis, dilated cardiomyopathy and low ejection fraction Recurrent pericarditis causing constriction Pericardial calcification
Amyloidosis	
Eye	Opacities over optic nerve head and retinal vessels, retinal thinning, macular atrophy, keratoconus

## DIFFERENTIAL DIAGNOSIS

Several diseases including other lysosomal storage disorders and hematological disorders have symptoms overlapping with Gaucher disease. The common differential diagnoses are tabulated in **Table 4**.

**Growth chart for Indian children**  
Weight-for-age and Height-for-age percentiles  
**Girls (5–17 years)**

**Figure 7** Growth trends in three girls with type 1 Gaucher disease before and after initiation of enzyme replacement therapy. Age at initiation of enzyme replacement therapy is marked by arrows. After initiation of enzyme replacement therapy, growth velocity has accelerated  
Source: Author's records.

**Figures 8A and B** Type 2 Gaucher disease. (A) Abdominal distension and umbilical hernia. Note the retroflexed posture of the neck; (B) Convergent squint and cachexia

**Table 4** Differential diagnosis of Gaucher disease

<i>Symptom complex mimicking Gaucher disease</i>	<i>Differential diagnosis</i>	<i>Distinguishing features in Gaucher disease</i>
Anemia Hepatosplenomegaly Horizontal gaze palsy Seizures including myoclonic seizures Pyramidal and cerebellar signs Gaucher cells in the bone marrow	Saposin C or prosaposin deficiency	Deficient $\beta$ -glucocerebrosidase activity ( $\beta$ -glucocerebrosidase activity is normal in Saposin C/prosaposin deficiency) Presence of pathogenic mutations in <i>GBA1</i> gene
Severe anemia Recurrent blood transfusions Hepatosplenomegaly Cells resembling Gaucher cells—pseudo-Gaucher cells in the bone marrow	Hemoglobinopathies	Disproportionately enlarged spleen in comparison to the liver, jaundice is uncommon Absence of characteristic red cell morphology on peripheral smear Manifestations of other organ involvement
Anemia Splenomegaly Hepatomegaly Abdominal pain Hypersplenism	Tropical splenomegaly	Presence of affected siblings Consanguinity Progressive splenomegaly not responding to antimalarial therapy Manifestations of other organ involvement Growth retardation Abdominal CT or MRI showing infiltration of the spleen and liver with or without infarcts or focal lesions
Severe anemia Thrombocytopenia Pancytopenia Bleeding manifestations Recurrent blood transfusions Hepatosplenomegaly Bone pains Cells resembling Gaucher cells—pseudo-Gaucher cells in bone marrow	Hematological malignancies <ul style="list-style-type: none"> <li>• Leukemia</li> <li>• Lymphoma</li> <li>• Myelodysplasia</li> </ul>	Leukopenia rather than very high white cell count Absence of blasts on peripheral smear Detection of characteristic Gaucher cell and absence of blast cells on bone marrow examination
Hepatosplenomegaly Psychomotor retardation Neurodegeneration Seizures Elevated chitotriosidase Chronic liver disease	Niemann-Pick disease type A/B GM1 gangliosidosis	Disproportionately enlarged spleen in comparison to the liver, absence of macular cherry red spot Detection of characteristic Gaucher cell and absence of histiocytes with foamy cells on bone marrow
Neonatal cholestasis Hepatosplenomegaly Psychomotor retardation Neurodegeneration Seizures Supranuclear ophthalmoplegia Mildly deficient $\beta$ -glucocerebrosidase activity Elevated chitotriosidase	Niemann-Pick disease type C	Disproportionately enlarged spleen in comparison to the liver, detection of characteristic Gaucher cell and absence of histiocytes with foamy cells on bone marrow
Hydrops fetalis	Several other lysosomal storage disorders like mucopolysaccharidosis, mucopolipidosis, sialidosis, GM1 gangliosidosis, Niemann-Pick disease type C, galactosialidosis, Farber disease and Wolman disease	Hepatosplenomegaly Absence of coarse facial features and dysostosis multiplex on radiographs Absence of vacuolated lymphocytes on peripheral blood smear Detection of characteristic Gaucher cell and absence of histiocytes with foamy cells on bone marrow
Osteonecrosis	Legg-Calve-Perthes disease	Multisystem involvement with hepatosplenomegaly and anemia, thrombocytopenia

## DIAGNOSTIC EVALUATION

Diagnosis is based on history to elicit typical symptoms. Family history for consanguinity and affected siblings should be obtained. Assessment on physical examination should include growth; skin for pallor, bruises and petechiae; abdomen for liver and spleen size; presence of clubbing and lymphadenopathy; heart, lungs, bones and neurological assessment. Undiagnosed splenomegaly and severe premature osteoporosis should be investigated for Gaucher disease.

## Bone Marrow Examination

This is not routinely required for diagnosis as reliable alternatives are available (enzyme activity and molecular diagnosis). Additionally, false-negative result is possible with bone marrow aspirate and false-positive result is obtained in the presence of pseudo-Gaucher cells. The latter can be found in a variety of disorders, such as multiple myeloma, Hodgkin's and non-Hodgkin's lymphoma, myelodysplasia, sickle cell anemia, thalassemia, chronic myeloid leukemia and tuberculosis and other mycobacterial diseases. However, an indication for examining the bone marrow is for the

**Figures 9A and B** (A) Type 3 Gaucher disease with significant pectus carinatum; (B) CT scan of the chest showing pectus carinatum

diagnosis of hematological malignancies associated with Gaucher disease.

### Definitive Diagnosis

This is based on demonstration of deficiency of  $\beta$ -glucocerebrosidase activity or by detection of pathogenic mutations in the *GBA1* gene. A fluorimetric assay estimates  $\beta$ -glucocerebrosidase activity in peripheral white blood cells, skin fibroblasts, chorionic villus and cultured amniotic fluid cells using the artificial substrate 4-methylumbelliferyl- $\beta$ -D-glucopyranoside. Recently, tandem mass spectrometry based assay for  $\beta$ -glucocerebrosidase activity is available from dried blood spot specimens collected on a filter paper. Those with Gaucher disease have  $\beta$ -glucocerebrosidase activity 0–30% of normal. Borderline low enzyme activity in peripheral blood leukocytes needs confirmation by estimation of enzyme activity in skin fibroblasts. There is no correlation between degree of enzyme deficiency and disease severity or phenotype.  $\beta$ -glucocerebrosidase activity estimation is not accurate for identification of carriers. Carrier detection requires molecular analysis.

Identification of the genotype by molecular analysis is recommended in every individual with Gaucher disease. One approach is to perform targeted mutation analysis for the four common mutations (N370S, L444P, 84insG and IVS2+1G>A) followed by sequence analysis of the coding region of the *GBA* gene if no mutation or a single common mutation is identified. This will identify 99% of disease causing alleles.

Molecular analysis aids in discriminating neuronopathic from non-neuronopathic disease. This is particularly useful to discriminate between type 1 and type 3 disease in early childhood as the signs in childhood are identical in both and the characteristic eye signs of type 3 disease may develop in later childhood. Genotype can guide the decision to initiate therapy and individualize the dose of enzyme replacement therapy if it predicts a severe phenotype. Molecular analysis is also useful for carrier detection, particularly for siblings or extended family members of the affected person and for prenatal diagnosis.

### Supportive Evidence of Gaucher Disease

Elevated biomarkers (chitotriosidase and PARC/CCL 18), hyperferritinemia, hyperimmunoglobulinemia and low total and high-density lipoprotein cholesterol. Chitotriosidase levels are 100–5,000 times the normal value.

### Baseline Assessments

After establishing diagnosis of Gaucher disease, assessments are performed to establish overall and organ-specific disease burden. These assessments also serve to monitor disease progression and response to therapy. The assessment protocol and modalities are enumerated in **Table 5**. Detailed description of the protocol for assessment is available in a review by Kaplan et al. Objective scores have been developed by Kallish and Kaplan to grade severity of the disease in children.

### TREATMENT

The various therapeutic modalities and supportive management for Gaucher disease are summarized in **Tables 6 and 7**. Enzyme replacement therapy is the current standard of care for Gaucher disease.

### Enzyme Replacement Therapy

Alglucerase [Ceredase®; Genzyme Corporation, Cambridge, MA, USA] was the first therapeutic product approved for use by the Food and Drug Administration (FDA) in 1991. It was derived from the human placenta. The naturally occurring enzyme was modified by removal of the sialic acid residues from terminal N-linked oligosaccharides to expose mannose residues. This step is critical for uptake of the enzyme into the lysosomes expressing the mannose-6-phosphate receptor. This ensured high rate of uptake of the exogenously administered enzyme by target cells. Subsequently, a human recombinant product, Imiglucerase [Cerezyme®; Genzyme Corporation, Cambridge, MA, USA] was approved by FDA in 1994. Imiglucerase is derived from expression of the human *GBA* gene in Chinese hamster ovary cells. Imiglucerase differs from the natural enzyme by a R495H amino acid substitution. It is modified to expose mannose residues to enhance uptake of the therapeutic molecule by macrophages. Two other products are now available: Velaglucerase [VPRIV®, Shire Plc], a recombinant product expressed in human fibroblast cell line, was approved in 2010 and Taliglucerase [Elelyso™, Pfizer/Protalix BioTherapeutics, Inc], a recombinant product expressed in carrot cell culture, was approved in 2012. Enzyme replacement therapy modifies the natural history of Gaucher disease by reversing the signs of the disease or preventing manifestation in the various organs. Therapy is indicated in all symptomatic individuals with type 1 and type 3 diseases (**Box 1**). It is not

**Table 5** Baseline evaluations after diagnosis of Gaucher disease is confirmed

S. No.	Assessment	Parameter
1.	Anthropometry	Height and weight
2.	Hematological	Hemoglobin concentration Platelet count White cell count Coagulation status (symptoms of bleeding, before surgical or dental procedures) Serum iron, ferritin, transferrin saturation Vitamin B <sub>12</sub> Immunoglobulin profile and immunoelectrophoresis
3.	Other blood tests	25-hydroxyvitamin D concentration Serum calcium/phosphorus/alkaline phosphatase Aspartate aminotransferase, alanine aminotransferase Serum total protein/albumin Serology: Hepatitis B and C, HIV Plasma chitotriosidase/PARC/CCL18/ACE/TRAP
4.	Spleen and liver volumes	Ultrasonography Abdominal MRI
5.	Cardiac	ECG, echocardiography with Doppler
6.	Skeletal	Plain radiographs of the femur (AP view) Thoracodorsal spine (lateral view) MRI of the entire femur and spine (sagittal scans) DEXA (lumbar spine and femoral neck)

**Abbreviations:** DEXA, dual-energy X-ray absorptiometry; MRI, magnetic resonance imaging; AP, anteroposterior; PARC, pulmonary and activation-regulating chemokine; TRAP, tartrate-resistant acid phosphatase; ACE, angiotensin-converting enzyme; CCL18, chemokine (C-C motif) ligand 18; HIV, human immunodeficiency virus.

indicated for type 2 disease. The recommended dose is 60 units/kg body weight administered as an infusion every 2 weeks. Response is dose-dependent. Doses should be individualized; lower doses of 30 units/kg have been used in children when the manifestations are not severe and titrated by the clinical response. In those having severe disease with hepatopulmonary syndrome or cirrhosis, the dose is increased to 120 units/kg body weight every 2 weeks.

**BOX 1** Indications for enzyme replacement therapy in symptomatic children with Gaucher disease

Any one or more of the following symptoms:

1. Symptomatic disease in the first two decades of life
2. Severe anemia; hemoglobin <8 mg/dL
3. Severe thrombocytopenia <60,000/mm<sup>3</sup>
4. Leukopenia, white cell count <3,000/mm<sup>3</sup>
5. Bone crisis and osteonecrosis in the past
6. Active bone disease, even if asymptomatic
7. Decreased growth velocity and/or growth retardation
8. Height <5th percentile or significantly decreased growth velocity
9. Delayed onset of puberty
10. Sibling with severe disease requiring enzyme replacement therapy
11. Genotype (L444P or D409H) associated with severe disease
12. A bone marrow density (BMD) Z score of – 2.0
13. Spleen and liver volumes >2.0 multiples of normal.

**Table 6** Therapeutic strategies and available modalities

S. No.	Strategy	Modality
1.	Enzyme enhancement therapy: Modification of mutated enzyme	Chaperones
2.	Supplement deficient enzyme • Direct	Enzyme replacement therapy Bone marrow transplant/ hematopoietic stem cell transplant
	• Indirect	Gene therapy
3.	Target substrate accumulation	Substrate reduction therapy

There is a variation in response of the various organs to enzyme replacement therapy. Anemia, thrombocytopenia and reduction of storage in the liver and spleen respond most dramatically (**Figs 10A to D**) whereas the response of the skeleton is slower. Organs such as lungs and lymph nodes are resistant to the effects of enzyme replacement therapy. The therapeutic enzyme does not cross the blood-brain barrier and, therefore, does not prevent or reverse neurological manifestations.

Therapeutic goals have been defined for monitoring response to enzyme replacement therapy to assess hematopoietic reconstitution, reduction in liver and spleen volumes and stabilization and improvement of bone disease. The goals are defined for each manifestation/organ system involved by the disease. A time frame to achieve each goal has also been defined (**Table 8**). After

**Figures 10A to D** Response to enzyme replacement therapy in type 3 Gaucher disease homozygous for L444P mutation. (A) Massive abdominal distension at initiation of enzyme replacement at 32 months of age; (B) Same child showing significant reduction in abdominal distension after 7 months of therapy; (C) After 1 year of therapy; (D) After 2 years of therapy

**Table 7** Supportive therapy of Gaucher disease

Blood transfusion
Splenectomy (total or partial; surgical or thromboembolism)
Treatment of bone crisis: <ul style="list-style-type: none"> <li>• Nonspecific pain: Nonsteroidal anti-inflammatory drugs</li> <li>• Excruciating pain: Prednisone 1 g/m<sup>2</sup> for 2 days, followed by lower doses</li> </ul>
Joint replacement surgery
Nutritional: <ul style="list-style-type: none"> <li>• Oral calcium and vitamin D supplements</li> <li>• Oral iron and/or vitamin B<sub>12</sub> supplements</li> </ul>
Bisphosphonates
Prevention of bleeding especially during surgical/dental procedures <ul style="list-style-type: none"> <li>• Desmopressin acetate (DDAVP)</li> <li>• Coagulation factor</li> <li>• Plasma transfusion</li> <li>• Platelet transfusion</li> </ul>

achieving therapeutic goals, the dose of enzyme replacement therapy may be reduced to maintain the goals.

## Alternative Modes of Treatment

### Substrate Reduction Therapy

N-butyldeoxynojirimycin available as Miglustat [Zavesca®; Actelion Pharmaceuticals, Allschwil, Switzerland] is an orally administered drug that inhibits production of the substrate glucosylceramide. It has been approved for use in adults with Gaucher disease in whom enzyme replacement therapy is not acceptable. It has not

been approved for treatment of children with Gaucher disease. A promising alternative oral substrate reduction drug is eliglustat tartrate, which is currently undergoing clinical trial in adults with type I disease.

### Enzyme Enhancement Therapy

Some mutations causing Gaucher disease like the N370S allele result in altered configuration of the protein. This misfolded protein may get destroyed before it reaches the lysosome or it can trigger a toxic cascade leading to cell apoptosis. Chaperones are small molecules that bind to misfolded proteins and result in correct refolding and/or maturation. Molecules such as iminosugars like isofagomine and the chemical chaperone N-nonyl-deoxynojirimycin have been shown to increase activity of mutant  $\beta$ -glucocerebrosidase. Ambroxol is being studied for its role as enzyme enhancement therapy in Gaucher disease, particularly in the neuronopathic type 3 variant.

### Bone Marrow and Hematopoietic Stem Cell Transplant

This therapy was previously advocated for Gaucher disease before the availability of enzyme replacement therapy. An advantage over enzyme replacement therapy is the effect on the CNS. Availability of a donor, need for immunosuppression and significant morbidity and mortality limit their use and enzyme replacement therapy currently continues to be the treatment of choice. Limited data indicate some benefit of hematopoietic stem cell transplant in type 3 disease.

## PREVENTION

As Gaucher disease is autosomal recessive, carrier parents have a 1 in 4 chance of having an affected offspring. The family should be

**Table 8** Therapeutic goals in children

Parameter	Goal	Time frame to achieve goal
Anemia	<ul style="list-style-type: none"> <li>• Increase hemoglobin levels to &gt;11 g/dL</li> <li>• Eliminate need for blood transfusions</li> <li>• Reduce fatigue and dyspnea</li> <li>• Maintain hemoglobin values achieved after the first 12–24 months</li> </ul>	1–2 years
Thrombocytopenia	<ul style="list-style-type: none"> <li>• Increase platelet count sufficient to prevent spontaneous and surgical bleeding</li> <li>• Avoid splenectomy</li> <li>• Moderate baseline thrombocytopenia <ul style="list-style-type: none"> <li>– Increase in platelet count by 1.5–2.0 fold</li> <li>– Approach low normal</li> </ul> </li> <li>• Severe baseline thrombocytopenia <ul style="list-style-type: none"> <li>– Increase in platelet count by 1.5 fold</li> <li>– Continue to increase</li> <li>– Normalization not expected</li> </ul> </li> <li>• Maintain stable platelet counts to eliminate risks of bleeding after a maximal response has been achieved</li> </ul>	First year  1 year 2 years  1 year 2nd to 5th year, doubling by second year
Hepatomegaly	<ul style="list-style-type: none"> <li>• Reduce and maintain liver volume to 1.0–1.5 times normal</li> <li>• Reduce liver volume by 20–30%</li> <li>• Reduce liver volume by 30–40%</li> </ul>	1–2 years 3rd to 5th year
Splenomegaly	<ul style="list-style-type: none"> <li>• Reduce and maintain spleen volume to 2–8 fold normal</li> <li>• Reduce spleen volume by 30–50%</li> <li>• Reduce spleen volume by 50–60%</li> <li>• Alleviate symptoms due to splenomegaly</li> <li>• Eliminate hypersplenism</li> </ul>	Within 1 year 2nd to 5th year
Bones	<ul style="list-style-type: none"> <li>• Lessen or eliminate bone pains</li> <li>• Prevent bone crisis</li> <li>• Prevent osteonecrosis and subchondral joint collapse</li> <li>• Improve bone mineral density (BMD); increase cortical and trabecular BMD</li> </ul>	1–2 years  2 years
Growth	<ul style="list-style-type: none"> <li>• Attain ideal or peak skeletal mass</li> <li>• Achieve normal height according to population standards</li> <li>• Achieve normal onset of puberty</li> </ul>	3 years

offered genetic counseling including information about the risk of recurrence. Prenatal diagnosis is possible in at-risk families by estimation of enzyme activity or genotyping in chorionic villi or cultured amniocytes.

### IN A NUTSHELL

1. Gaucher disease is an autosomal recessive single gene disorder caused by mutations of the *GBA1* gene leading to functional deficiency of the lysosomal enzyme  $\beta$ -glucocerebrosidase.
2. Spectrum of clinical manifestations is a continuum ranging from asymptomatic individuals to severe fetal manifestations. The major phenotypes, neuronopathic and non-neuronopathic disease are distinguished by the presence of primary neurological involvement.
3. Massive splenomegaly and hepatomegaly are the most consistent manifestations, often accompanied by anemia and thrombocytopenia.
4. Skeletal involvement is the most debilitating manifestation that is present in more than 80% of cases and may be suboptimally recognized.
5. Diagnosis requires demonstration of deficient  $\beta$ -glucocerebrosidase activity and/or molecular analysis to detect pathogenic mutations in the *GBA 1* gene. Bone marrow examination is not routinely recommended for diagnosis.
6. Carrier detection requires molecular analysis. Carrier couples must be offered genetic counseling and prenatal diagnosis.
7. The current standard of therapy is enzyme replacement therapy with macrophage targeted recombinant human glucocerebrosidase infusions administered intravenously. Enzyme replacement therapy reverses most manifestations of Gaucher disease but has no effect on CNS manifestations.

## Chapter 3.11

# Niemann-Pick Disease

Ashwin Dalal

Niemann-Pick disease (NPD) is a subgroup of lysosomal storage disorders characterized by accumulation of lipids in various organs of the body. Traditionally, NPD has been classified into four groups based on biochemical and clinical criteria, i.e., group A (NP-A) with classic patients having neurodegenerative disease leading to death in infancy; group B (NP-B) patients having organomegaly without nervous system involvement; group C (NP-C) patients with slowly progressive neurologic illness; and group D (NP-D) patients who closely resembled group C, but were limited to Nova Scotia region of Canada. Genetic studies have revealed that NPD type A/B (NP-A/B) are sphingolipidosis disorders caused due to deficiency of acid sphingomyelinase (ASM) enzyme resulting from mutations in *SMPD1* gene, whereas NPD type C/D (NP-C/D) are cholesterol trafficking defects resulting from mutations in *NPC1* and *NPC2* genes. Although the etiopathology of both disorders is completely different, the two diseases are discussed together for historical reasons.

## EPIDEMIOLOGY

The prevalence among Ashkenazi Jews is estimated to be approximately 1 in 40,000 for NP-A/B whereas overall prevalence

among other populations is estimated to be 1 in 250,000. The incidence of NPD type C is estimated to be 1 in 150,000. There are very few studies available from India and the exact prevalence is not known.

## PATHOLOGY

The histochemical hallmark of NPD is the foam cell, which is, in fact, lipid-laden macrophage. They are also called NPD cells and appear as sea blue histiocytes on bone marrow examination (**Fig. 1**). In NP-A, the brain is shrunken with reduced weight of cerebrum and cerebellum. Neurons are swollen and myelin is decreased. Similar changes are seen in spinal cord and peripheral nerves. Visceral involvement is seen as massively enlarged spleen along with involvement of lymph nodes, liver and kidneys. Lung involvement is more prominent in NP-B cases. The central defect in NP-C is defective intracellular trafficking of lipids which results in accumulation of cholesterol in the lysosomes and may lead to a deficiency in membrane cholesterol. Glycosphingolipid accumulation is seen as sea blue histiocytes in bone marrow with Giemsa Wright stains.

## Biochemistry

Acid sphingomyelinase (sphingomyelin phosphodiesterase) is the enzyme which degrades sphingomyelin into ceramide and phosphatidylcholine (**Fig. 2**). NP-A/B is characterized by deficiency of ASM, which results in accumulation of sphingomyelin in various tissues. The type of lipids stored in reticuloendothelial system in patients with both NP-A and NP-B is similar in all tissues

**Figure 1** Giemsa-stained bone marrow aspiration smears showing large foamy histiocytes (arrows)  
Source: Dr Ashwani Tandon, Department of Pathology, Nizam's Institute of Medical Sciences, Hyderabad.

**Figure 2** Chemical basis of acid sphingomyelinase action

with the exception of lysosphingolipids which are seen to be elevated in brains of patients with NP-A and not in NP-B. This may be the reason for non-neuronopathic presentation in patients with NP-B. In patients with NP-A/B, the enzyme activity ranges from undetectable to 5% of normal. ASM enzyme activity is measured in leukocytes or fibroblasts using artificial fluorogenic substrates. Enzyme activity is proportional to the fluorescence released. However, enzyme assay is not reliable to detect carriers of NP-A/B since there is great degree of overlap between carriers and normal individuals. The primary biochemical defect in NP-C is aberrant intracellular transport of endocytosed cholesterol. Deficiency of NPC1/NPC2 leads to accumulation of unesterified cholesterol in the late endosome/lysosomal compartments. Specific diagnosis of NP-C can be done by filipin staining of cultured fibroblasts grown in presence of low-density lipoproteins (LDL). Filipin binds to the excess unesterified cholesterol and is seen as dense birefringent granules in cytoplasm. ASM activity is normal in leukocytes. Chitotriosidase activity is a biomarker which is known to be moderately increased in NPD.

### Genetics

Niemann-Pick disease type A, type B and type C are inherited in autosomal recessive fashion. Homozygous or compound heterozygous mutations in SMPD1 result in NP-A/B whereas NP-C results from mutations in NPC1 and NPC2 genes. Risk of recurrence in next pregnancy is 25% for a couple with previous child with NPD.

The *SMPD1* gene is located at 11p15 and codes for ASM protein. Both NP-A and NP-B result from mutations in *SMPD1* gene. Hence, these diseases are called allelic disorders. More than 100 different mutations have been reported worldwide, which include missense, nonsense, frame shift and splice site mutations. The full spectrum of mutations in Indian patients is not yet known. Most of the mutations are private mutations limited to a family except in Ashkenazi Jews. NP-C is caused due to mutations in *NPC1* or *NPC2* genes, of which 95% of patients have mutations in *NPC1*. The *NPC1* gene has been mapped to 18q11 whereas *NPC2* gene has been mapped to 14q24, is about 13.5 kb in length and has 5 exons. More than 200 mutations have been reported in NP-C, mostly missense mutations scattered throughout the gene.

### CLINICAL FEATURES

Acid sphingomyelinase deficiency results in a spectrum of phenotypes ranging from classic NPD type A with early infantile

onset and neurologic involvement to the mild NPD type B with later onset and only visceral involvement. Patients with NPD type C present with manifestations ranging from visceral involvement to neuropsychiatric presentation.

### Classic Niemann-Pick Disease Type A

Patients commonly present with abdominal distension at 3–4 months age, due to hepatosplenomegaly. Other presenting complaints can be feeding problems, failure to thrive, gastrointestinal complaints (e.g., constipation, diarrhea and vomiting), recurrent respiratory infections and irritability. There is progressive increase in size of liver and spleen leading to massive hepatosplenomegaly (**Fig. 3A**). Neurological examination may be normal at the time of presentation except for hypotonia. However, as the disease progresses, there is progressive hypotonia and loss of deep tendon reflexes. Psychomotor development does not progress beyond the 1-year level for any domain and there may be loss of milestones attained. Fundus examination may reveal cherry red spot in most patients (**Fig. 3B**). Neurologic deterioration is relentless, and most children do not survive beyond 2–3 years of age.

### Niemann-Pick Disease Type B

The onset of symptoms is much later and many of the patients live into adulthood. Typically patients present with abdominal distension with mild to severe hepatosplenomegaly. Significant splenomegaly may result in hypersplenism with secondary thrombocytopenia. Pulmonary involvement is seen ranging from limitation of activity to oxygen dependence. Up to one-third of individuals with NPD-B have a cherry red spot in retina. Failure to gain height and delayed skeletal maturation may lead to significant short stature in adulthood.

### Niemann-Pick Disease Type C

Patients present with varied clinical features depending on age of onset and it may take a long time until diagnosis is established. Clinical features based on age at presentation are listed in **Table 1**. The typical finding associated with NP-C is impaired vertical gaze, which is an early manifestation. Vertical supranuclear gaze palsy first manifests as increased latency in initiation of vertical saccades, after which saccadic velocity gradually slows and is eventually lost. In late stages of the illness, horizontal saccades are also impaired. In addition, there may be

**Table 1** Clinical features of Niemann-Pick disease type C according to age of presentation

Age of presentation	Clinical features
Perinatal	Fetal ascites detected on antenatal sonography Severe neonatal liver disease with jaundice and persistent ascites
Infantile	Hypotonia, delayed psychomotor development Hepatosplenomegaly
Childhood	Clumsiness, frequent falls progressing to ataxia Vertical supranuclear gaze palsy (VSGP) Dystonia, dysarthria Partial and/or generalized seizures
Adolescent/adult	Slowly progressive neurologic deterioration Dementia, psychosis, psychiatric illness Ataxia, VSGP may be present

extrapyramidal and psychiatric symptoms. Hence, a high degree of suspicion is needed to diagnose the condition.

### APPROACH TO DIAGNOSIS

The approach to diagnosis of NPD is similar to any other storage disorder. Presence of hepatosplenomegaly with or without

neuronal involvement should raise the suspicion for NPD, especially once infective and hematological causes have been ruled out. Presence of cherry red spot on fundus examination is a very important clue. Estimation of ASM enzyme is helpful in making a confirmed diagnosis of NP-A/B. Mutation analysis of *SMPD1* gene helps to identify the mutation and confirms the diagnosis (**Fig. 3C**). In addition, mutation analysis helps in accurate carrier detection and prenatal diagnosis.

The diagnosis of NP-C is difficult due to varied clinical features and needs high degree of suspicion. The diagnosis can be confirmed by sequencing of *NPC1* and *NPC2* genes for identification of mutations. Differential diagnosis for various manifestations of the NPD is listed in **Table 2**.

### MANAGEMENT

The management of patients with NPD is multidisciplinary since various organs are involved. The extent of disease in NP-A needs to be established by complete neurological and ophthalmological evaluation followed by complete blood counts and liver function tests. In addition, NP-B patients have to be evaluated by chest X-ray, pulmonary function tests and liver biopsy when indicated. Although there is no curative treatment for NP-A, supportive treatment like treatment of seizures, dietary advice and occupational therapy can be helpful. NP-B patients will need treatment for hypersplenism,

**Figures 3A to C** (A) Affected patient showing coarse facies and hepatosplenomegaly; (B) Cherry red spot; (C) Sequence chromatogram depicting exon 2 of *SMPD1* showing homozygous c.1262T>G mutation (arrows)

**Table 2** Differential diagnosis for different presentations of Niemann-Pick disease

<i>Niemann-Pick disease type A/B</i>	
Hepatosplenomegaly	Gaucher disease, Sandhoff disease, Wolman disease, mucopolysaccharidoses and oligosaccharidoses
Interstitial lung disease	Environmental exposures, connective tissue diseases and infections
Cherry red spot	GM1 gangliosidosis, Sandhoff disease, Tay-Sachs disease, sialidosis, galactosialidosis, mucopolipidoses
<i>Niemann-Pick disease type C</i>	
Severe neonatal jaundice	Biliary atresia, congenital infections, $\alpha$ -1 antitrypsin deficiency, tyrosinemia
Splenomegaly	Storage diseases, infections, hematologic malignancies, histiocytosis
Vertical supranuclear gaze palsy	GM2 gangliosidosis, mitochondrial diseases, glycine encephalopathy, maple syrup urine disease, dorsal midbrain syndrome
Dystonia	Idiopathic torsion dystonia, dopa responsive dystonia, Wilson's disease, amino and organic acidopathies (e.g., glutaric aciduria type 1), GM2 gangliosidosis
Dementia	Pseudodementia (depressive disorder), neuronal ceroid lipofuscinoses, subacute sclerosing panencephalitis, HIV encephalopathy

use of supplemental oxygen or steroids for pulmonary involvement and surveillance for liver failure. Bone marrow transplantation (BMT) has shown variable results. It holds promise in NP-B patients since neurologic involvement is not corrected by BMT in NP-A patients. However, morbidity and mortality associated with BMT limit its use. Trials are underway for enzyme replacement therapy and gene therapy for NP-A/B.

Treatment of NP-C is primarily supportive and includes anticonvulsants for treatment of seizures, symptomatic treatment of dystonia, and cataplexy, physical therapy, speech therapy and dietary advice. Liver and bone marrow transplant have not been successful. Several new therapies under investigation include inhibition of glycosphingolipid synthesis by N-butyldeoxynojirimycin, use of miglustat for stabilization of NPC protein, and neurosteroid replacement therapy with allopregnanolone.

## PREVENTION

Niemann-Pick disease is not curable. Hence, the best strategy is to prevent birth of children with disease. Primary prevention to avoid the birth of first affected child in a family can be done if all the couples can be screened for mutations in *NPD* genes and offered prenatal diagnosis where both parents are carriers for disease causing mutations. This strategy is possible in genetic isolates like Ashkenazi Jews where a few mutations account for all cases of NPD. However, in other populations, secondary prevention can be done by prenatal diagnosis in families where a proband with NPD has been identified. Confirmed diagnosis in proband based on enzyme analysis and/or mutation analysis is a prerequisite for prenatal diagnosis. Prenatal diagnosis can be done by chorionic villus biopsy (11–13 weeks gestation) or amniocentesis (16–18 weeks gestation) followed by enzyme analysis and/or mutation analysis. Genetic testing is more accurate. The couple can opt for termination of pregnancy if the fetus is found to be affected. Expanded family screening can also be offered to these families to prevent birth of a child with NPD in siblings of parents.

## IN A NUTSHELL

1. Niemann-Pick disease is a lysosomal storage disorder characterized by accumulation of sphingolipids in various tissues.
2. Niemann-Pick disease type A is neuronopathic form caused due to deficiency of ASM resulting from mutations in *SMPD1* gene. NPD type B is an allelic disorder with only visceral involvement.
3. Niemann-Pick disease type C is a cholesterol trafficking defect resulting from mutations in *NPC1* and *NPC2* genes.
4. Patients with NPD commonly present as storage disorder with or without neurologic involvement.
5. The gold standard for diagnosis of NP-A/B is ASM enzyme assay whereas NP-C is diagnosed by filipin staining of fibroblasts grown with LDL.
6. Mutation analysis helps in confirmation of diagnosis, accurate carrier detection and prenatal diagnosis.
7. There is no cure for NPD and management is mainly supportive.
8. Prevention can be done by carrier screening in inbred populations or secondary prevention by prenatal diagnosis using enzyme assay/mutation analysis.

## Chapter 3.12

# Fabry Disease

Ratna Dua Puri

Anderson Fabry disease (OMIM No. 301500) is an X-linked lysosomal storage disorder with a frequency of about 1 in 40,000 males. The disease manifests due to deficiency of enzyme  $\alpha$ -galactosidase A ( $\alpha$ -gal A) as a result of mutations in the *GLA* gene. Heterozygous females have intermediate levels of enzyme activity and can manifest milder manifestations of the disease. The disease phenotype in patients is due to the accumulation of the glycosphingolipid substrate, globotriaosylceramide (Gb3) in the lysosomes as a consequence of  $\alpha$ -gal A deficiency.

### PATHOPHYSIOLOGY

The glycosphingolipid primarily deposits in the lysosomes of the walls of small arteries, epithelial cells of cornea, glomeruli and renal tubules, cardiac muscles, ganglion and perineural cells of the autonomic nervous system and small unmyelinated nerves. Heterogenous clinical manifestations of Fabry disease are as a result of this widespread, progressive Gb3 accumulation in various organ systems.

### CLINICAL MANIFESTATIONS

Clinical manifestations are varied and multiple organ systems are involved. Young patients present with the classical phenotype, whereas those with greater residual enzyme activity present later, with milder manifestations or an organ-specific variant phenotype. Manifestations are typically more severe in affected males than carrier females. However, a small number of carrier females can develop severe symptoms indistinguishable from males, though at a later age. Female phenotype is classically due to skewed X inactivation or rarely due to 45X or an X-autosome translocation with disruption of the  $\alpha$ -galactosidase (*GLA*) gene at the breakpoints.

Though the phenotypic presentations of Fabry disease are always thought of as those in childhood, adolescence and adulthood, they essentially represent a continuum of phenotype due to increasing Gb3 deposition with time. Patients present with two major phenotypic manifestations, the severe classic phenotype and the variant/atypical forms.

#### Severe Classic Phenotype

Typical onset is in childhood or adolescence with clinical manifestations related to the autonomic and peripheral nervous system as well as vascular cutaneous and eye lesions. This includes the pain crisis, angiokeratomas, temperature intolerance, hypohidrosis and eye lesions. Renal, cardiac and cerebrovascular presentations manifest late in the third to fifth decade of life.

#### Pain

With an onset in childhood or adolescence, the *episodic Fabry crisis* is a hallmark of onset of clinical symptoms. It is an agonizing, burning pain in the palms and soles that radiates to the extremities and other parts of the body. The pain can be triggered by fever, emotion, stress, exercise, rapid changes in temperature and humidity and is extremely debilitating. It lasts from minutes to days. Misdiagnosis as rheumatic fever, neuralgia or neurosis is due to the accompanying fever and elevated erythrocyte sedimentation rate. Abdominal and flank pain mimics appendicitis or renal colic. The crisis decreases in frequency and severity with increasing age. Though an important and constant phenotype, pain may be absent in 10–20% patients.

The *constant discomfort* in some patients is burning and tingling paresthesias of hands and feet. These acroparesthesias are an attenuated crisis and many patients modify lifestyle to cope with the discomfort.

#### Skin

The typical lesions are angiokeratomas that manifest between 9 years and 13 years of age and are one of the earliest manifestations of the disease. They are raised, purplish-red, non-blanching lesions present on the hips, back, thighs, buttocks, penis and scrotum, as well as the oral mucosa and conjunctiva (**Fig. 1**). One-third female carriers also manifest these lesions. Other dermatological manifestations include hypohidrosis and unexplained fever due to intolerance to rising temperature.

**Figure 1** Angiokeratomas in a child with Fabry disease  
Source: Dr Madhulika Kabra, AIIMS, New Delhi.

#### Eye Manifestations

Involvement of the cornea, lens, conjunctiva and retina are reported. The characteristic spiral streaks in the corneal epithelium, *cornea verticillata* are seen as a corneal opacity on slit-lamp examination. It is present in over 90% patients, including heterozygous women and is pathognomonic of Fabry disease. Lenticular involvement as *Fabry cataract* is present in 30% affected males. The corneal and lens changes do not interfere with vision. Dilatation and tortuosity of the retinal and conjunctival vessels may be present.

#### Renal Involvement

Proteinuria/microalbuminuria can be present in adolescence without significant renal disease. The impaired glomerular filtration rate and tubulopathy are seen in the third decade in the classical presentation of the disease. Chronic kidney disease is the main cause of premature death in untreated patients by the fifth decade of life. Females are typically less severely affected.

#### Cardiac Disease

In patients with classical presentation, this presents by middle age. The earliest changes include a short PR interval, bradycardia, valvular insufficiencies and diastolic dysfunction. Conduction system abnormalities include ST segment abnormalities, T wave inversion and dysrhythmias. Rhythm abnormalities may lead to fatal arrhythmias. Hypertrophic cardiomyopathy in the absence of long-standing hypertension and left outflow obstruction should alert the clinician to a diagnosis of Fabry disease. In different studies, 3–12% patients with unexplained cardiac left ventricular hypertrophy have Fabry disease. Angina, variant angina and

myocardial infarction can occur due to pathology in the coronary vascular bed. Raynaud's phenomenon is also commonly reported in Fabry patients. Cardiac events are the most common cause of premature death in patients undergoing dialysis or transplantation for end-stage renal disease.

### Cerebrovascular Manifestations

The phenotype is due to the vascular complications of the central nervous system and is seen in about 13% of Fabry patients. Central nervous system (CNS) symptoms occur in the third decade in males and fourth decade in females. The presentations are transient ischemic attack, seizures, hemiplegia, aphasia, labyrinthine disorders, cerebral hemorrhage and cryptogenic stroke.

### Gastrointestinal Lesions

These include abdominal pain, diarrhea and vomiting.

### Miscellaneous

Sensorineural hearing loss, dyslipidemia, depression, anxiety and other psychological manifestations are reported.

### Variant Phenotypes

These are the atypical presentations without the characteristic skin lesions, pain crisis and sweating abnormalities. They present between the third and fifth decades of life with cardiac, renal or cerebrovascular manifestations. **Table 1** summarizes the different phenotypic manifestations in Fabry disease patients.

### Time to Diagnosis

The natural history studies show a long period to diagnosis from onset of initial symptoms. In children with median age at onset of symptoms was 9 years and diagnosis was made at 23 years of age and 13 and 32 respectively in women. A high index of suspicion is essential for early diagnosis and timely intervention to prevent progression to end-stage organ damage.

### Survival Data

Survival data prior to availability of enzyme replacement therapy (ERT) is reported to be 57 years for males and 72 years for females in a study of 96 Dutch Fabry patients.

## DIAGNOSIS

### Clinical

The diagnosis can be clinically suspected in classical Fabry patients by the history of acroparesthesias and associated angiokeratomas

and corneal dystrophy. In childhood, recurrent unexplained fever with pain in hands and feet should alert the astute clinician to the diagnosis. In suspected heterozygous females, slit lamp and examination for angiokeratomas in the trunk, breasts, back and posterolateral thighs are important. Adult onset phenotypes include renal sufficiency of unknown etiology, cryptogenic stroke and unexplained left ventricular hypertrophy. There is extreme heterogeneity of presentation and a Fabry patient may present with a single symptom or a combination of different organ involvements.

### Estimation of Enzyme Activity

Classically affected males will have no detectable or less than 1%  $\alpha$ -gal A levels measured in plasma, leukocytes or dried blood spots. Males with atypical phenotypes have residual activity more than 1% measured in plasma or isolated leukocytes. If enzyme levels are markedly decreased in heterozygous females, it is diagnostic of their carrier status. Conversely, normal enzyme levels in carrier females are reported.

### Gb3Cer, Globotriaosylceramide/GL3

It is the main glycosphingolipid that accumulates. GL3 levels in blood or urine have been used for diagnosis and assessment of disease burden.

### Mutation Analysis

Patients with Fabry disease harbor mutations in the *GLA* gene. These are mostly point changes though deletions and insertions are also reported. Clear genotype-phenotype correlation is not present. However, mutations causing complete loss of function of the gene are associated with the classical phenotype, whereas amino acid substitutions with some resultant enzyme activity present with the variant phenotypes. Identification of the mutation is a useful, additional confirmation of the enzymatic and clinical diagnosis in the male and is also important to identify female carriers. Knowledge of the familial mutation is important for predictive testing for at-risk family members and also for prenatal diagnosis.

A scheme for baseline and follow-up evaluation is suggested in **Table 2**.

## MANAGEMENT

Management of patients with Fabry disease is multidisciplinary (**Fig. 2**).

### Enzyme Replacement Therapy

Definitive management with two recombinant, commercially available enzymes, agalsidase alpha (Replagal®, Shire Human

**Table 1** Clinical manifestations in Fabry disease

Manifestation	Classical Fabry	Cardiac variant	Renal variant	Cerebrovascular variant

LVH	+	++/cardiomyopathy	+	–

Abbreviations: GI, gastrointestinal; ESRD, end-stage renal disease; LVH, left ventricular hypertrophy; TIA, transient ischemic attack.

Genetic Therapies, Inc.) and agalsidase beta (Fabrazyme®, Genzyme Corp.) is available since 2001. The enzyme is administered as an intravenous infusion once every 2 weeks and is taken up by the vascular endothelial and the parenchymal cells into the lysosomes. The recommended dose for agalsidase alpha is 0.2 mg/kg/2 weeks and that for agalsidase beta is 1 mg/kg/2 weeks.

The drug is shown to decrease the accumulated cellular GL3. Clinical benefits in the classical phenotype include improvement in peripheral neuropathy and hypohidrosis. Renal disease benefits are better if treatment is initiated at less advanced renal dysfunction as lost renal function is not recovered and progression of disease cannot be halted. It is uncertain if ERT reduces the incidence of stroke in treated patients. In addition to delaying the progression of renal disease, therapy also reduces the risk of major cardiac, CNS and renal events by 60%.

### Supportive Management

Symptomatic management with angiotensin converting enzyme/angiotensin II receptor blocker (ACE/ARB) inhibitors is recommended to manage proteinuria and protect renal function. Hypertension, if present, is to be managed appropriately. Antiplatelet drugs, statins for dyslipidemia, stroke prophylaxis are other important supportive modalities. Cardiac pacing can be done if AV blocks are present. Drugs used for the management of the painful crisis, pain and constant discomfort include diphenylhydantoin, carbamazepine and gabapentin.

### Genetic Counseling and Prenatal Diagnosis

Fabry disease is an X-linked disorder with major manifestations in males. However, some female carriers can have clinical manifestations of the disease. Once a diagnosis is established in a male member, it is important to counsel the parents/family members

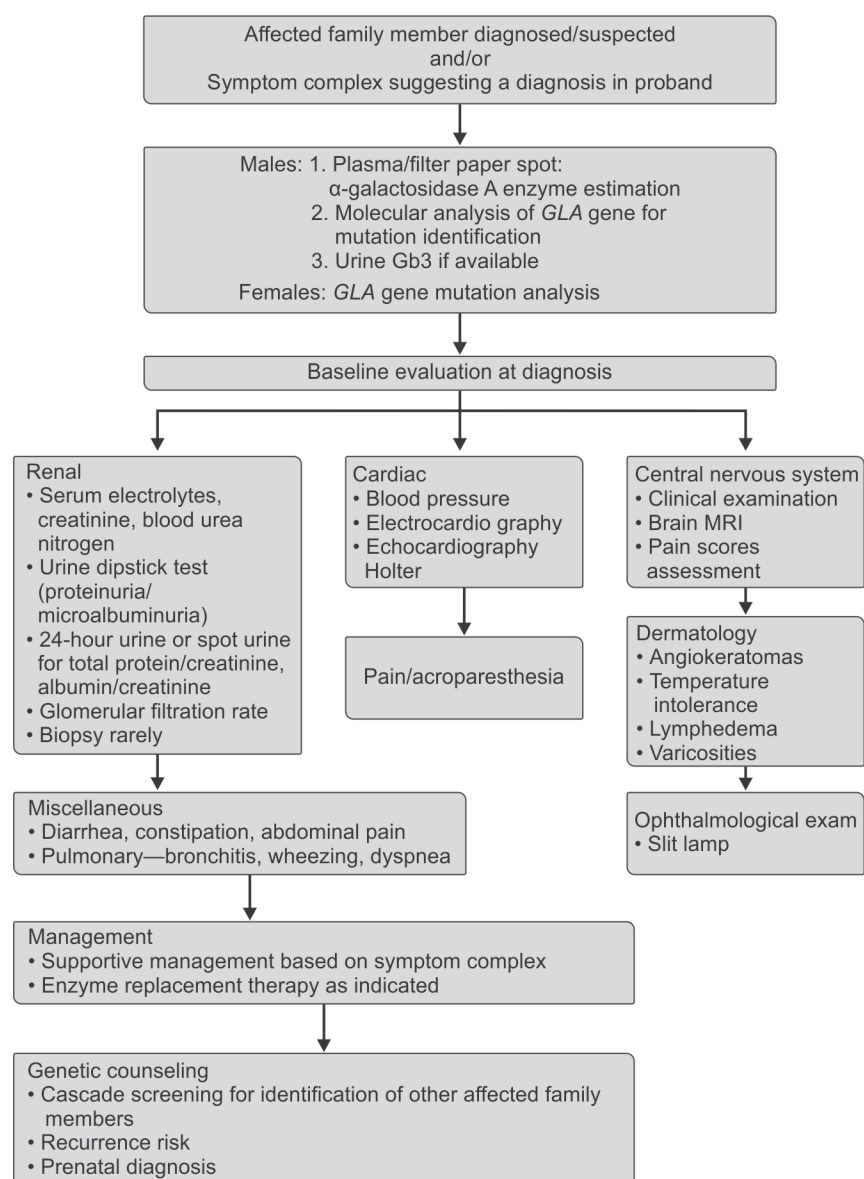

about the disease and its implication. Availability of ERT should be discussed. The limitation of cost of therapy and options available to the family are important concerns. Screening of at-risk family members to identify early any affected persons is extremely helpful. Prevention in subsequent pregnancies by chorionic villus sampling after 10 completed weeks of gestation is discussed with the families.

### IN A NUTSHELL

1. Fabry disease is an X-linked lysosomal storage disorder due to deficiency of enzyme  $\alpha$ -gal A as a result of mutations in the GLA gene.
2. Heterozygous females have intermediate levels of enzyme activity and can manifest milder manifestations of the disease.
3. The disease phenotype is due to the accumulation of the glycosphingolipid substrate, Gb3 in the lysosomes.
4. The glycosphingolipid primarily deposits in the lysosomes of the walls of small arteries, epithelial cells of cornea, glomeruli and renal tubules, cardiac muscles, ganglion and perineural cells of the autonomic nervous system and small unmyelinated nerves.
5. Clinical manifestations are varied and multiple organ systems are involved. Young patients present with the classical phenotype, whereas those with greater residual enzyme activity present later with milder manifestations or an organ specific variant phenotype.
6. The diagnosis can be clinically suspected in classical Fabry patients by the history of acroparesthesias and associated angiokeratomas and corneal dystrophy.
7. Classically affected males will have no detectable or less than 1%  $\alpha$ -gal A levels measured in plasma, leukocytes or dried blood spots.
8. Definitive management with two recombinant, commercially available enzymes, agalsidase alpha and agalsidase beta is available since 2001.

**Table 2** Baseline and follow-up evaluation in Fabry disease

Organ system		Features	Timeline
Neurological	History	Acroparesthesia, hypohidrosis, heat and cold intolerance, fatigue, stroke-related symptoms, transient ischemic attack, seizures	Baseline and every 6 months
	Examination	Stroke, hemianesthesia, hemiplegia, aphasia	Baseline and every 6 months
	Investigations	Brain MRI  Stroke risk factors: Serum lipids Factor V Leiden, serum homocysteine, protein C and S, antithrombin III, lupus anticoagulant, anticardiolipin antibody	Baseline and at onset of any central nervous system event Annually Once at baseline
Renal	Urine examination	Protein, casts, red cells and birefringent lipid globules 24-hour urine or spot urine for total protein/creatinine, albumin/creatinine, creatinine clearance	Baseline and thereafter: Three monthly if chronic kidney disease (CKD) 1 or 2 and >1 g/day proteinuria or CKD4 Six monthly if CKD3
	Blood	Serum electrolytes, creatinine, blood urea nitrogen	Every 12 months if CKD1 or 2 and <1 g/day proteinuria
Cardiac	History	Resting bradycardia, palpitations, exertional dyspnea, angina, myocardial infarction	Baseline and every 6 months
Miscellaneous			At baseline and then as clinically indicated
Audiometry			Every visit
Ophthalmological		Blood pressure	Baseline and then every other year till 35 years of age. Yearly thereafter
Pulmonary		ECG, echocardiography	
Gastrointestinal			
Skeletal

## Chapter 3.13

# Defects of Carbohydrate Metabolism

Kausik Mandal

Defects of carbohydrate metabolism can be classified in two broad categories: (1) diabetes: includes type 1 and type 2 diabetes; and (2) inborn errors of carbohydrate metabolism. Diabetes is a collection of disorders leading to high blood glucose. The etiology of diabetes ranges from environmental causes, genetic predispositions to pure single gene disorders like lipotrophic diabetes (BSCL2). It will be discussed along with other endocrine

disorders in Section 44. This chapter will deal with classification and clinical implications of inborn errors of carbohydrate metabolism.

### CLASSIFICATION

Classifying inborn errors of carbohydrate metabolism is difficult; an exhaustive list will overlap with disorders within and outside the pathways involved in metabolism of various carbohydrates and a precise list will miss out on many disorders related to various carbohydrates. The various important disorders are summarized in **Table 1**, and some of the relatively common disorders are discussed below.

### Glucose Transport Defects

Glucose transporter proteins are found in various target tissues. These proteins facilitate glucose diffusion across plasma membrane. To date more than 14 such proteins have been identified. Some of the important ones and their disorders are described below:

**Table 1** Classification of inborn errors of carbohydrate metabolism

Broad categories	Types of disorders under each category	Subtypes/features	Special features
Disorders of monosaccharide metabolism	Glucose-galactose malabsorption	This is a rare autosomal recessive disorder, single gene disorder ( <i>SLC5A1</i> gene)	Newborns present with profuse watery diarrhea; which stops on dietary restriction of glucose and galactose; later on might develop nephrocalcinosis
	Glucose transport defects	More than 14	GLUT10 defect is also called arterial tortuosity syndrome
	Disorders of galactose metabolism	Galactokinase deficiency	High galactose in blood, but no mental retardation
		Galactose-1-phosphate uridyl transferase deficiency	Also known as GALT deficiency/ galactosemia
		UDP galactose-4-epimerase deficiency	Also known as epimerase deficiency
	Disorders of fructose metabolism	Essential fructosuria	A benign autosomal recessive condition; increased intermittent excretion of fructose in urine
Hereditary fructose intolerance		In contrast to essential fructosuria, this condition needs prompt diagnosis	
Gluconeogenic disorders	Fructose 1,6-bisphosphatase deficiency	Autosomal recessive disorder due to mutation in the <i>FBP1</i> gene	Excellent prognosis if diagnosed within time
	Phosphoenolpyruvate carboxykinase deficiency	Two forms: PCK1 and PCK2	Hypoglycemia
	Pyruvate carboxylase deficiency	<i>PC</i> gene	Three clinical forms: Type A, B and C
	Deficiencies of pyruvate dehydrogenase complex	PDHC is an enzyme complex; encompasses various disorders	Extreme variability in clinical expression; these children do not present with hypoglycemia
Disaccharidase deficiencies	Lactase deficiency	Congenital lactase deficiency is due to mutation in the <i>LCT</i> gene	Acquired deficiency is also described
	Sucrase-isomaltase deficiency	Found in Eskimos	Management is sacrosidase (Sucraid) enzyme and a diet with limited sucrose
Disorders of pentose metabolism	Transaldolase deficiency	Autosomal recessive condition arising from mutation in the <i>TALDO1</i> gene located at 11p	Great phenotypic variability, ranging from hydrops fetalis to slowly progressing cirrhosis of liver
	Ribose-5-phosphate isomerase deficiency	Mutation in <i>RPIA</i> gene at 2p	Extremely rare; developmental delay and epilepsy are features
	Essential pentosuria	Autosomal recessive condition due to mutation in the <i>DCXR</i> gene at 17q	Benign disorder; requires no treatment
Congenital disorders of N-linked glycosylation	Many types	Briefly discussed in this chapter	
Glycogen storage disorders	Many types	Discussed in the subsequent chapter	

Abbreviations: UDP, uridine diphosphate; PCK, phosphoenolpyruvate carboxykinase; PDHC, pyruvate dehydrogenase complex.

### Glucose Transporter 1 Deficiency Syndrome

**Etiology** Glucose transporter 1 (GLUT1) deficiency syndrome is normally inherited in autosomal dominant fashion due to de novo mutation in the *SLC2A1* gene (located at 1p); autosomal recessive inheritance has also been described. GLUT1 protein is localized in the blood-brain barrier.

**Features** Children with GLUT1 defects present with severe seizure disorder, developmental delay, spasticity, ataxia and gradually developing microcephaly. Sometimes these children might have atypical childhood absence epilepsy and paroxysmal movement disorders.

**Diagnosis** Low cerebrospinal fluid (CSF) glucose relative to blood glucose and low CSF lactate is virtually diagnostic of this disorder.

**Management** A ketogenic diet partially or completely ameliorates the accompanying seizure disorder.

### GLUT2 Defect/Fanconi-Bickel Syndrome

**Etiology** Fanconi-Bickel syndrome is a rare but well-defined autosomal recessive clinical entity characterized by proximal renal tubular dysfunction and hepatorenal glycogen accumulation. Homozygous or compound heterozygous mutation in the *SLC2A2* gene (located on 3q) causes defect in GLUT2 transporter protein, resulting in defective monosaccharide transport across the membranes. Though also classified under glycogen storage disorder (GSD), use of the term GSD type XI is discouraged for this disorder.

**Features** These children might have a doll-like face and present with hypotonia, short stature, rickets and hepatomegaly (**Fig. 1**).

**Diagnosis** Laboratory features suggest renal rickets (low calcium and phosphorus, high alkaline phosphatase and normal vitamin D levels), proximal tubular defects (low urinary specific gravity, glycosuria, bicarbonaturia, phosphaturia and proteinuria), deranged liver function [abnormal prothrombin time (PT) and activated partial thromboplastin time (aPTT), hypercholesterolemia and hypogammaglobulinemia] and early morning hypoglycemia with postprandial hyperglycemia.

**Management** Management issues are guided toward prevention of early morning hypoglycemia and management of renal rickets.

### Disorders of Galactose Metabolism

Disorders of galactose metabolism give rise to increased galactose in blood. Galactosemia however refers to galactose-1-phosphate uridyl transferase deficiency. The major pathway for the metabolism of galactose is described as the Leloir pathway (**Fig. 2**). The three principal enzymes and the defects in the galactose metabolism pathway are designated as: galactokinase deficiency, galactose-1-phosphate uridyltransferase deficiency (GALT deficiency/galactosemia) and UDP-galactose-4-epimerase (GALE) deficiency (epimerase deficiency).

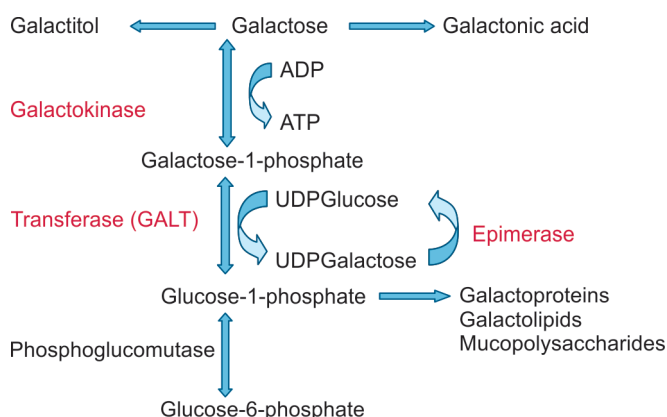

All the three enzyme deficiencies can be picked up during newborn screening by identifying increased amount of galactose or galactose-1-phosphate in dried blood spot (Guthrie card), provided the baby is on breastfeed or formula containing lactose. The specific enzyme defect is identified by enzyme assay in erythrocytes (blood needs to be drawn in heparin before the baby receives any blood transfusion). Multiplexing for detection of all the three enzymes can be done by methods using tandem mass spectrometry (MS/MS).

### Galactokinase Deficiency

**Etiology** This is an autosomal recessive disorder due to mutation in the *GALK1* gene (located on 17q). Due to galactokinase deficiency, galactitol and galactonic acid are produced following diversion of

**Figure 1** Child with Fanconi-Bickel syndrome with doll-like facies, short stature, hypotonia, rickets and hepatomegaly

**Figure 2** Metabolism of galactose/the Leloir pathway

galactose into secondary pathways. Accumulation of galactitol is the likely cause of cataract and sometimes cerebral edema.

**Features** Children suffering from galactokinase deficiency present with cataract; they might also develop pseudotumor cerebri. They however do not have mental retardation, jaundice or hepatomegaly as found in GALT deficiency.

**Diagnosis** Diagnosis is aided by a very high galactose in blood (may be as high as 100 mg/dL) after a lactose containing diet. Confirmation is by galactokinase enzyme activity in erythrocytes; this enzyme is very unstable at room temperature and special precautions need to be taken before ordering such tests.

**Management** Early treatment with lactose free diet and removal of galactose from diet prevents progression of cataract.

### Galactosemia (Galactose-1-phosphate Uridyltransferase Deficiency)

**Etiology** Galactosemia is an autosomal recessive condition caused by homozygous or compound heterozygous mutation in the *GALT* gene (located at 9p). As per the underlying mutation, residual erythrocyte GALT enzyme activity, levels of galactose metabolites (e.g., erythrocyte galactose-1-phosphate and urine galactitol), clinical manifestations and outcome, galactosemia can be described under three subcategories: classic galactosemia, clinical variant galactosemia and biochemical variant galactosemia.

**Features** Babies with classic galactosemia develop life-threatening events including feeding problems, hypoglycemia, hepatocellular damage, bleeding diathesis, jaundice and failure to thrive soon after starting breastfeeding or formula containing lactose. Sepsis with gram-negative organisms (notably *Escherichia coli*) may culminate in septic shock and death if these babies remain untreated. Infants, who survive the neonatal period, may develop severe brain damage if not started on lactose-free diet. If lactose-free diet is started in the first 3–10 days of life, the symptoms resolve rapidly and prognosis remains favorable for liver failure.

Even with early and adequate management, the long-term outcome in case of classic galactosemia can be unsatisfactory; there may be speech defects, poor intellectual function, neurologic deficits (tremor, dystonia and ataxia), growth failure, premature ovarian insufficiency and cataracts.

Clinical variant galactosemia has near identical manifestations as the classical variety and probably a favorable long-term outcome with early and adequate treatment.

**Diagnosis** In classic galactosemia, erythrocyte GALT enzyme activity is absent or barely detectable. Erythrocyte galactose-1-phosphate may be very high and usually is more than 10 mg/dL in the newborn period. When the patient is on a lactose-free diet, the level is more than and equal to 1 mg/dL (normal level of erythrocyte galactose-1-phosphate is <1 mg/dL). Plasma-free galactose is also very high and is usually more than 10 mg/dL.

**Management** Prevention of primary manifestations: Any newborn who is *screen-positive* during newborn screening or have clinical symptoms and biochemical parameters positive for galactosemia should be put on immediate dietary intervention while sample is sent for definitive diagnosis. If a baby is found to have classic galactosemia restriction of galactose intake should be continued and all milk products need to be replaced with lactose-free formulas. While growing up, they should be cautious to avoid casein or whey-containing foods and medicines containing lactose and galactose.

**Treatment of manifestations** Childhood speech problems including dysarthria require expert speech therapy. Developmental assessment and continued care is needed for developmental delay. Special education is required for school going children. Hormone replacement therapy may be required for delayed puberty and/or primary or secondary amenorrhea in females. Sometimes cataract surgery may be required.

**Prevention of secondary complications** Calcium and vitamin supplements help to prevent osteoporosis.

**Family evaluation** Evaluation of at-risk siblings at the earliest is required to prevent complications. Mutation testing in the affected baby and prenatal testing should be offered to the family.

### UDP Galactose-4-Epimerase Deficiency (Epimerase Deficiency)

**Etiology** This is an autosomal recessive condition due to mutation in the *GALE* gene (at 1p).

**Features and diagnosis** UDP-galactose 4-epimerase deficiency is categorized into severe and benign forms. Severe form is very rare (only few cases reported), and should be considered in individuals with liver disease, failure to thrive, who have elevated erythrocyte galactose-1-phosphate concentrations but normal erythrocyte GALT enzyme activity. The benign form is more common and is mostly identified during newborn screening.

**Management** The severe form requires dietary restriction like classic galactosemia. The outcome is uncertain. The benign form probably does not require much intervention.

### Disorders of Fructose Metabolism

Fructose is found abundantly in fruits, honey and various vegetables. Fructose in combination with glucose forms sucrose, which is a disaccharide. Liver is the major organ for fructose metabolism (**Fig. 3**). Here fructose is phosphorylated to fructose-1-phosphate (F-1-P) in presence of the enzyme fructokinase. Fructokinase is not present in muscle and adipose tissue; in these tissues, enzyme hexokinase converts fructose to fructose-6-phosphate.

Figure 3 Fructose metabolism

### Hereditary Fructose Intolerance

Hereditary fructose intolerance (HFI) is a condition with devastating outcome if it remains undiagnosed. This condition is also referred to as fructosemia.

**Etiology** The underlying defect is deficiency of liver F-1-P aldolase (aldolase B). This condition is inherited in autosomal recessive fashion due to mutation in the *ALDOB* gene (at 9q).

**Features** HFI becomes apparent during infancy when sucrose and fructose-containing food are introduced while weaning. Children may present with recurrent vomiting, abdominal pain and hypoglycemia, which might be fatal at times. Continued exposure to fructose will result in growth failure, liver damage and renal tubulopathy. Some children might develop aversion to sweets and fruits as a compensatory mechanism to avoid symptoms; they might get diagnosed late during the course. Rarely, some might have a milder course and get diagnosed in adolescent or adulthood.

**Diagnosis** Peripheral blood cannot be used for enzyme assay since the enzyme is not present in leukocytes or red blood cells. Enzyme assay needs to be done in liver biopsy specimen or in intestinal mucosa. Enzyme activity is usually less than 10% of normal when F-1-P is used as the substrate, and is between 10% and 50% of normal when fructose 1,6-bisphosphate is used as the substrate. Diagnosis is aided by clinical symptoms and large amounts of fructose in urine. Most such children might also show a gross generalized aminoaciduria.

A fructose tolerance test can be done with caution for diagnosis. Administration of fructose, orally or parenterally, causes fall in the blood glucose (due to inhibition of glycogenolysis by F-1-P), fall in serum inorganic phosphate (due to its increased utilization during formation of F-1-P), rise in serum uric acid (arising from rapid degradation of purine) and lactic acidosis.

**Differential diagnosis** HFI may biochemically resemble tyrosinemia since there may be elevation of blood tyrosine and methionine in view of liver damage. The generalized aminoaciduria and hypoglycemia may resemble that found in galactosemia patients.

**Management** Prompt recognition and avoidance of fructose and sorbitol from diet has been shown to reverse liver and renal damage. Overall outcome including neurological function is found to be good in children, who are adequately managed.

## Gluconeogenic Disorders

There are various metabolic processes which interplay for the maintenance of glucose homeostasis in our body. During fasting, glucose is derived from breakdown of glycogen (glycogenolysis) or conversion of lactate and certain amino acids like glutamate, aspartate and alanine to glucose (gluconeogenesis). Gluconeogenesis primarily takes place in the liver and kidneys (**Fig. 4**). The overall process is partly controlled by the endocrine system. In cases of key enzyme deficiencies, there is hypoglycemia and lactic acidosis.

### Fructose 1,6-Bisphosphatase Deficiency

**Etiology** This is an autosomal recessive gluconeogenic disorder arising from mutation in the *FBP1* gene (located on 9q).

**Features** Children suffering from this disorder, present during infancy with hypoglycemia, lactic acidosis and ketosis following a trivial infection and/or fasting (**Fig. 5**). They may have periods of hyperventilation. Sometimes, manifestations are delayed and present action may resemble ketotic hypoglycemia. There may be hepatomegaly; but liver and kidney functions are normal.

**Diagnosis** The clinical picture along with detection of metabolites in urine by gas chromatography-mass spectrometry (GCMS), helps in diagnosis of the disorder. The enzyme assay needs to be done in liver tissue; so mutation analysis is a preferred method for confirmation of diagnosis. In view of hypoglycemia and hepatomegaly, this disorder is often confused with GSD type I; however, these children do not have the typical doll-like facies associated with GSD I.

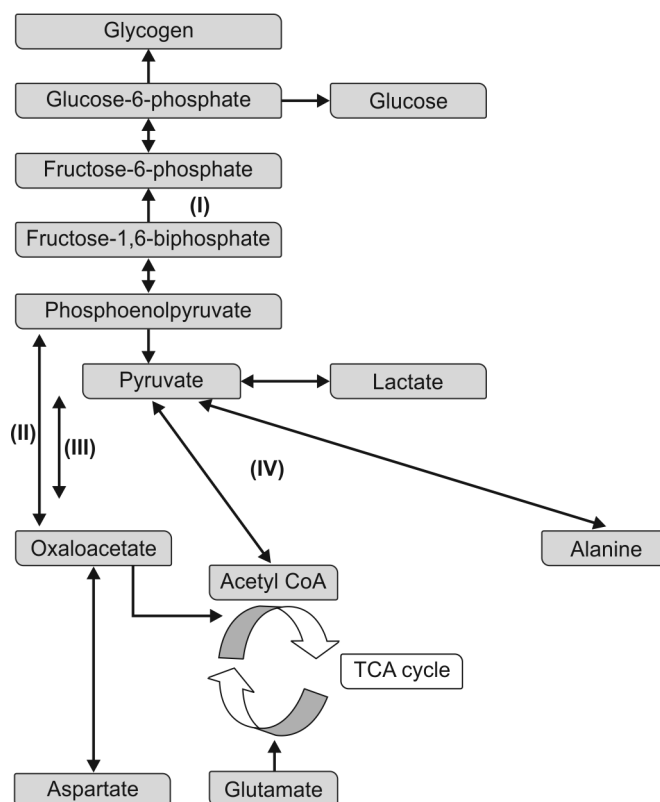

**Management** At times, undiagnosed, children may die in the neonatal period or early infancy; however, once recognized in time, most will have excellent outcome. Management consists of frequent feeding and avoidance of long periods of fasting. Avoidance of fructose and sorbitol in food and use of folic acid has been suggested.

### Pyruvate Carboxylase Deficiency

**Etiology** Pyruvate carboxylase deficiency is inherited in autosomal recessive fashion. The putative gene is located on 11q.

**Features** Affected children generally present in the neonatal period with metabolic acidosis due to increased lactic acid, hypotonia, hyporeflexia, refusal to feed and failure to thrive. Death might occur within first few months. Children surviving the neonatal period may present with seizures, hypotonia, metabolic acidosis and growth failure. Three clinical forms have been described: type A (infantile or North American form), type B (neonatal or French form) and type C (benign form). Genotype-phenotype correlation has been established.

**Diagnosis** Laboratory findings include metabolic acidosis with lactic acidosis, ketonemia and a near normal lactate/pyruvate ratio (exception is type B). There may be concomitant hypoglycemia,

**Figure 4** Gluconeogenesis. The positions of various enzymes/enzyme complex shown in Roman numerals are (I) fructose 1,6-bisphosphatase, (II) phosphoenolpyruvate carboxykinase, (III) pyruvate carboxylase, (IV) pyruvate dehydrogenase complex

**Figure 5** A normal looking 1-year-old child with fructose 1,6-bisphosphatase deficiency. He presented with episodic hypoglycemia, lactic acidosis and ketonuria, following trivial infections. He had hepatomegaly. Diagnosis is confirmed after mutation testing of the *FBP1* gene

Source: Dr Shubha R Phadke, SGPGIMS, Lucknow.

hyperammonemia, citrullinemia and hyperlysinemia. Such disorders are suspected when a baby with metabolic acidosis is being evaluated using arterial blood gas, serum lactate, ammonia, blood sugar and metabolic screen by tandem mass spectrometry and/or GCMS.

Low enzyme activity has been demonstrated in liver, leukocytes and skin fibroblasts. Enzyme activity in cultured amniocytes

has been used for prenatal testing in at-risk families. Definitive diagnosis is by mutation testing.

**Management** Supportive treatment is required to correct metabolic acidosis, dehydration and hypoglycemia. Peritoneal dialysis to reverse metabolic derangement has been tried. Biotin and thiamine have also been used in some patients. Ketogenic diet as a treatment for epilepsy should be avoided. Overall outcome remains poor even with all supportive measures.

### Deficiencies of Pyruvate Dehydrogenase Complex (PDHC)

As the name suggests, PDHC is an enzyme complex with three major enzymes (E1, pyruvate dehydrogenase or pyruvate decarboxylase; E2, dihydrolipoyl transacetylase; and E3, dihydrolipoyl dehydrogenase), and five coenzymes. Pyruvate dehydrogenase is composed of four subunits, two E1 alpha and two E1 beta. The alpha subunit is X-linked encoded by *PDHA1* gene located on Xp.

There is extreme variability in clinical expression in view of underlying biochemical and genetic heterogeneity. These children might have lactic acidosis, but they do not have hypoglycemia, unlike other disorders of gluconeogenesis. Patients with neonatal PDHC deficiency generally die within first few months of life. Most other children have neurological manifestations ranging from developmental delay, seizures, microcephaly and ataxia. In view of complexity and variability of this enzyme system, diagnosis and pinpointing the basic defect by enzyme assay remains difficult.

Treatment with ketogenic diet low is recommended; however, overall outcome remains unfavorable. Somewhat favorable outcome has been reported in patients with dihydrolipoyl dehydrogenase deficiency, who are treated with lipoic acid treatment and diet low in branched chain amino acids.

### Disaccharidase Deficiencies

The major carbohydrates in our diet are starch (which is broken down to maltose, maltotriose, isomaltose and alpha-limit dextrins), lactose and sucrose. Deficiency of disaccharidases causes accumulation of undigested disaccharides leading to bacterial overgrowth.

#### Etiology

Acquired deficiencies are common due to following acute intestinal infections, which causes damage to the brush border of the small intestine. They are mostly transient and resolve with time. There can be inherited deficiencies due to mutation in certain genes.

#### Lactase Deficiency

Lactase deficiency is found to happen in two different clinical settings with mutation in two different genes which lie near one another. *Congenital lactase deficiency* presenting in early infancy is found commonly in Finnish population. It is inherited in autosomal recessive pattern due to mutation in the *LCT* gene (lactase gene) located at 2q. The *adult onset form* called lactase non-persistence is probably inherited in autosomal dominant fashion, found commonly in Mediterranean, African-American and Asian population. With time it has been perceived that the disease is due to noncoding sequence variations in *MCM6* gene; located upstream of the lactase gene (at 2q).

#### Sucrase-Isomaltase Deficiency

This disorder is inherited in autosomal recessive pattern due to mutation in the *SF* gene located on 3q.

#### Features of Disaccharidase Deficiency

The symptoms of disaccharidase deficiency are abdominal pain, flatulence, diarrhea and perianal redness. Stools are acidic, foamy and watery. Following milk feeds, babies with congenital lactase deficiency present with diarrhea, dehydration, acidosis and weight loss.

### Diagnosis

Disaccharidase deficiencies are diagnosed using a challenge test, where there is a flat blood glucose curve with increased breath hydrogen concentration, after ingestion of the suspected disaccharide.  $^{13}\text{C}$ -sucrose labeled breath test is useful for sucrase-isomaltase deficiency.

Definitive diagnosis can be done by enzyme assay in small bowel biopsy specimen or by mutation testing of the putative gene.

### Management

Management of lactase deficiency is avoidance of lactose in diet. Lactose-free infant formulas are readily available these days. It is, however, important to differentiate the acquired causes, where lactose-free formula need not be continued for long.

### Disorders of Pentose Metabolism

Hexose monophosphate pathway is an alternative pathway of glucose metabolism, which caters to around 10% of the total glucose metabolized in our body. This shunt leads to formation of pentoses and provides nicotinamide adenine dinucleotide phosphate (NADPH). The important disorder, glucose-6-phosphate dehydrogenase (G6PD) deficiency, is linked to this pathway. It, however, is not generally described under carbohydrate metabolism; and more commonly described under hemolytic anemia. The abnormalities related to pentose metabolism are very rare and only described as few case reports.

### Congenital Disorders of N-Linked Glycosylation

#### Etiology

Many proteins undergo post-translational modification. Glycosylation is addition of oligosaccharides or glycans on these proteins. These glycans are of two types designated as per their linkage to the protein, O-linked and N-linked. N-linked refers to those bound to the amide group of asparagine.

Congenital disorders of N-linked glycosylation, also called the CGDs are a group of disorders caused by deficiency of various enzymes (around 42 different enzymes) in the N-linked synthetic pathway. They are genetically heterogenous, most inherited as autosomal recessive fashion; some are X-linked. These days nomenclature includes the word CDG linked to the gene involved; this makes description easier than the old nomenclature with numerical and alphabetical system.

#### Features

As glycosylated proteins have widespread distribution, most such disorders have multisystem manifestations. Most disorders begin in infancy, manifesting as severe developmental delay and hypotonia with multiple organ system involvement. In the other end of the spectrum, there are children presenting with protein-losing enteropathy with normal development. Only few individuals are described in each type; making understanding of each phenotype difficult.

PMM2-CDG (*CDG-Ia*) is the most common type reported; it has a highly variable presentation and clinical course. The clinical progression is divided into infantile multisystem stage, late-infantile and childhood ataxia-intellectual disability stage, and adult stable disability stage. The classical diagnostic clue of *inverted nipples* and *abnormal fat distribution* (**Figs 6A and B**) may not be present in many children. The typical neurological features are slow-rolling vertical and horizontal eye movements with slow head movement in neonatal period along with hyporeflexia and hypotonia. There can be alternating internal strabismus, seizures, stroke-like episodes, stupor and coma. Some might present with intracranial hemorrhage. Various changes are described in neuroimaging ranging from myelination defects to atrophic changes.

## Diagnosis

The diagnostic test for most types of CDGs is transferrin isoform analysis, mostly done by isoelectric focusing of serum transferrin to determine the defect in sialylated N-linked oligosaccharides linked with serum transferrin. Other methods including capillary electrophoresis have also been used. Exact enzymatic defect is difficult to be determined; molecular testing by gene panels has been more readily used for definitive diagnosis and prenatal testing.

## Management

Most infants and children with all types of CDG require nutritional supplements [except MPI-CDG (*CDG-Ib*)]. Many may require nasogastric tube or gastrostomy tube feedings. Supportive therapies for gastroesophageal reflux, developmental delays, ocular findings, stroke-like episodes, orthopedic issues, etc. are required. For MPI-CDG (*CDG-Ib*), mannose is given as 1 g/kg/day in five divided oral doses. It is found to normalize hypoproteinemia and coagulation defects; it also improves the protein-losing enteropathy and hypoglycemia associated with MPI-CDG.

Acetaminophen and other agents metabolized by the liver need to be avoided.

Care should be taken about coagulation status before surgery in view of increased risk of bleeding and deep venous thrombosis.

## Glycogen Storage Disorders

Glycogen is the principle storage form of carbohydrate in our body. GSDs are a group of disorders that affect glycogen metabolism. The glycogen is of abnormal quality, quantity or both. These disorders are described in the subsequent chapter.

### IN A NUTSHELL

1. Though disorders of carbohydrate metabolism are rare, they need to be suspected in certain clinical settings with hypoglycemia and lactic acidosis.
2. Galactosemia is being incorporated in newborn screening program. A timely intervention might minimize neurological disabilities in the affected babies.
3. Some of the disorders like fructose 1,6-bisphosphatase deficiency and HFI have very good prognosis, if recognized and treated in time. Most of them require avoiding certain foods and refraining from fasting states.
4. Some disorders like essential fructosuria are benign disorders; they only require reassurance.
5. Most disorders are autosomal recessive conditions. They are prone to recur in the family. The recurrence risk is 25% for autosomal recessive and X-linked recessive disorders.
6. A definitive diagnosis by enzyme assay and/or mutation testing in the affected child is a priority.
7. Various metabolites in blood and urine can be tested by tandem mass spectrometry (MS/MS) and GCMS; these methods can be used as screening tests for difficult to recognize metabolic disorders.
8. When there is diagnostic dilemma, testing for gene panels for specific group of disorders or exome sequencing might help in finding the putative gene.

## Chapter 3.14

# Glycogen Storage Diseases

Priya S Kishnani, Stephanie Austin

Glycogen storage diseases (GSDs) are caused by the inability to synthesize or metabolize stored glycogen. In some GSDs, there is an accumulation of normally structured glycogen while in others the structure of glycogen is abnormal. GSDs are categorized either chronologically by discovery or by the type of tissue involved, which primarily includes liver, muscle and cardiac tissue. To date, over twelve glycogen metabolism disorders have been catalogued. Hepatic GSDs include types I, III, IV, VI, IX and XI. Muscle GSDs include types II, III, V, VII and IX. Hepatic glycogenoses cause hepatomegaly and fasting hypoglycemia, whereas the muscle glycogenoses can cause muscle weakness and cramps during exercise. Progressive limb-girdle muscle weakness occurs in some patients, especially those with Pompe disease (GSD II).

The phenotypic expression of the gene defects involved in GSDs greatly varies and both the age of onset of symptoms and the rate of progression can be different for the same enzymatic defect. Symptoms can either be correlated with the degree of residual enzyme activity or with different mutations in the genes. With the exception of hepatic phosphorylase kinase deficiency and lysosomal-associated membrane protein 2 (LAMP2) deficiency, which are inherited as X-linked recessive traits, all of these disorders are inherited as autosomal recessive traits.

Glycogen storage diseases are most often diagnosed at a young age due to the early onset of symptoms. Treatment for GSDs affecting the liver often involves maintaining glucose levels by regulating the release of glucose into the bloodstream. Treatment for GSDs that affect muscles often involves avoiding muscle weakness by limiting exercise or increasing protein intake. Early treatment is imperative to reducing the severity of the symptoms of GSDs.

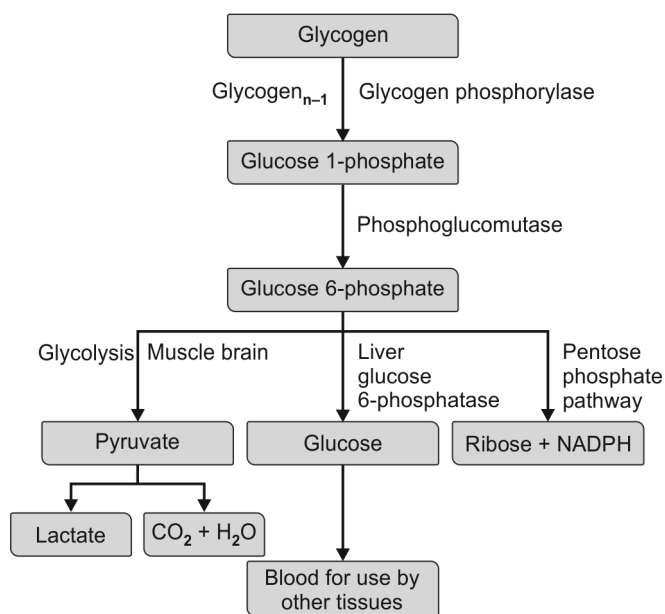

## ETIOLOGY

Glycogen storage diseases are genetic disorders. The majority of GSDs are due to autosomal recessive inheritance, with the exception of a few forms that are due to X-linked inheritance (hepatic phosphorylase kinase deficiency and LAMP2 deficiency). The genetic mutations that result in each GSD cause a defect in a particular enzyme that affects glycogen metabolism.

## PATHOGENESIS

Normal glycogen metabolism is shown in **Figure 1**. A schematic diagram showing different GSDs and their pathways is shown in **Figure 2**. GSD type I has two biochemical subtypes: GSD Ia and GSD Ib, each derived from deficiencies in particular components of the glucose-6-phosphatase complex. The defects in both type Ia and type Ib lead to inadequate hepatic conversion of glucose-6-phosphate to glucose through normal glycogenolysis and gluconeogenesis and make affected individuals susceptible to fasting hypoglycemia. GSD II will be discussed in Chapter 3.15 on Pompe disease.

Glycogen storage disease type III is due to a deficiency of the debrancher enzyme, necessary to cleave the 1,6 linkages in the outer branches of the glycogen molecule, resulting in the accumulation of glycogen with short branch points (limit dextrin) because of incomplete glycogenolysis. In type IIIa, many patients develop a progressive myopathy due to the deficiency of both liver and muscle debrancher enzyme. Type IIIb, in which

**Figure 1** Normal glycogen metabolism

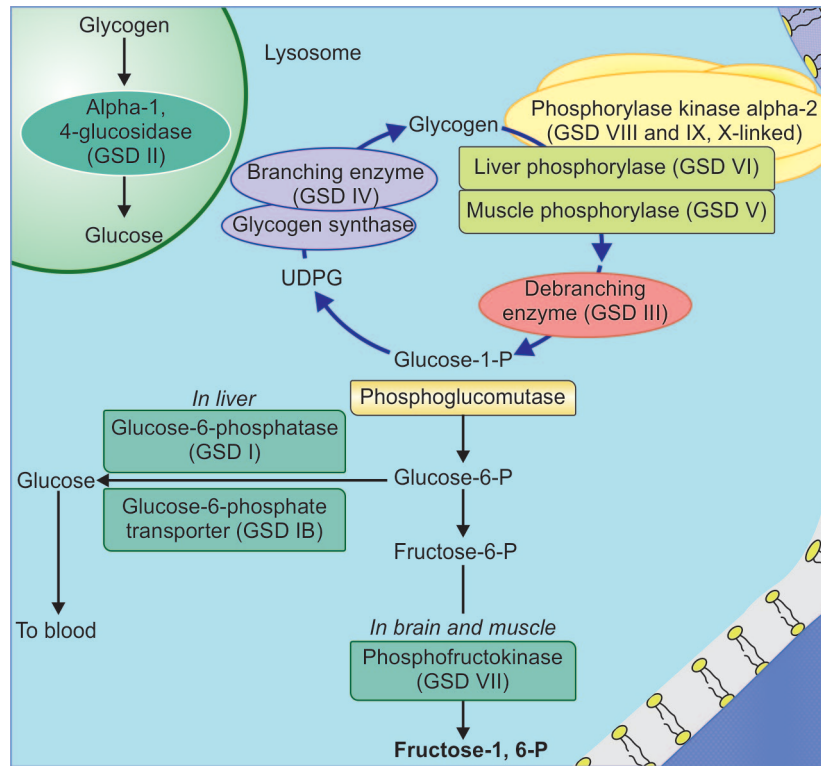

the deficiency is only in the liver, is less common. Patients have fasting hypoglycemia, but unlike patients with GSD I, infants with debrancher deficiency can tolerate longer fasts due to active phosphorylase and intact gluconeogenesis. When the feeding times are spaced many hours apart or when the child is unable to feed because of illness, hypoglycemia can occur.

Glycogen storage disease type IV, Andersen's disease, is the most variable of the GSDs. The deficiency of the brancher enzyme produces amylopectin, an abnormal glycogen with few branch points. GSD type V, McArdle's disease, is one of the most common GSDs. It is caused by a deficiency of myophosphorylase. This enzyme is necessary for the cleavage of glucose-1-phosphate from glycogen. Lack of production of glucose-1-phosphate impairs energy production through the glycolysis pathway, leading to muscle weakness and cramping. GSD type VI is caused by a deficiency of hepatic phosphorylase, which is regulated by a complex system of activators. Phosphorylase kinase activates this enzyme and is, in turn, activated by other enzymes such as hepatic cAMP-dependent protein kinase.

Glycogen storage diseases type VII, Tauri's disease, is caused by a deficiency of the muscle isozyme of phosphofructokinase. GSD IX, which is also one of the most common GSDs, is caused by deficiency of phosphorylase b kinase (PhK). PhK activates liver and muscle glycogen phosphorylase and is composed of four copies each of four subunits and the most common subtype of liver PhK deficiency, which affects about 75% of patients, is inherited in an X-linked manner.

## CLINICAL FEATURES

Patients with GSD I type Ia may present in the first few months of life with hypoglycemia, lactic acidosis, and hepatomegaly. There may be typical *doll-like facies* (**Fig. 3**). Because none of the glycogens can be converted directly to glucose, hypoglycemia occurs soon after the last meal and can cause hypoglycemic seizures. The resulting excess glucose-6-phosphate is shunted through the Embden-Meyerhof pathway, causing excessive production of lactic acid, lipid synthesis and hyperuricemia. The pathways for gluconeogenesis also become activated, adding to the production of these intermediary metabolites. Other manifestations include

**Figure 2** Different glycogen storage diseases and their pathways

**Figure 3** A child with glycogen storage disease type I. Note hepatomegaly and chubby appearance

impaired platelet function, recurrent renal disease, pancreatitis, and hepatic adenomas. Type 1b disease also causes impaired neutrophil function with risk for recurrent infections and inflammatory bowel disease.

The clinical spectrum for patients with GSD type III is broad, with some infants resembling type I disease and some patients presenting later in life. Hepatomegaly, elevated liver enzymes (Aspartate transaminase, Alanine transaminase) and hyperlipidemia are seen in patients with GSD IIIa and IIIb. Patients with GSD IIIa usually do not experience clinical symptoms of myopathy until the third or fourth decade of life. Cirrhosis, portal hypertension, hepatocellular carcinoma, and liver failure may occur and be progressive. Patients can also develop

widespread myopathy including weakness of the proximal and distal small muscles of the hand. In addition, some patients have abnormal nerve conduction studies. Patients with GSD IIIa may develop cardiac hypertrophy, and are at risk for life-threatening arrhythmias. Cardiac manifestations are extremely variable; there is no correlation between extent of involvement of liver, heart and skeletal muscle.

The classic presentation of GSD type IV includes failure to thrive, hepatosplenomegaly, progressive cirrhosis of the liver, and death in childhood. Other presentations include an infantile form sharing characteristics of infantile Pompe disease, such as childhood progressive myopathy and cardiomyopathy, and an adult-onset form involving polyglucosan body disease, which affects both the central and peripheral nervous system. In patients with progressive liver presentation, liver enzymes are elevated. Additionally, in late stages, synthetic function decreases to 1–10% of normal function. Hypoglycemia can be a feature in cases with progressive liver cirrhosis. Biopsy material from involved tissue shows Periodic Acid-Schiff (PAS)-positive inclusions and characteristic fibrillar aggregates of amylopectin.

Most patients with GSD type V present in childhood with muscle fatigue, cramps on routine exercise, and myoglobinuria with strenuous exercise. Patients with myophosphorylase deficiency often demonstrate a *second-wind phenomenon*. Attributed to increased oxidative capacity, this anomaly is caused by increased glucose infusion during exercise. The blood creatine kinase (CK) is usually elevated, especially when the patient is symptomatic.

Clinical presentation in GSD type VI is variable, ranging from mild to severe. Hepatomegaly and growth retardation mark the childhood clinical course. Hypoglycemia, hyperlipidemia, mild to moderate elevations of serum transaminase values, and hyperketosis are typical laboratory findings. Hepatomegaly usually improves as the patient ages, although those with a more severe presentation have presented with significant hepatomegaly, recurrent severe hypoglycemia and postprandial lactic acidosis.

In patients with GSD type VII, glycolysis is impaired, causing fatigue, cramps from exercise and myoglobinuria. Patients rarely present with infantile hypotonia or progressive myopathy.

A common symptom of patients with GSD type IX is liver PhK deficiency which is more often seen in males, although some female carriers may exhibit symptoms. Children with liver PhK deficiency usually present in the first 2 years of life with short stature and abdominal distention from moderate to marked hepatomegaly, all of which usually improve by adolescence. The clinical severity varies considerably and some patients can be very involved with significant liver disease. This is usually seen in patients with the gamma variant form of the disease. Symptoms include hyperketotic hypoglycemia, hypotonia, mild gross motor delays, and liver fibrosis. Some patients can have progressive liver cirrhosis and liver failure. In rare cases, presentation includes liver adenoma and renal tubular acidosis.

Muscle-specific PhK deficiency is a rarely reported X-linked condition with a clinical presentation ranging from exercise intolerance, with myoglobinuria and muscle cramping, and progressive muscle weakness presenting from childhood to adulthood, to a virtually asymptomatic condition. Serum CK may be normal.

## DIFFERENTIAL DIAGNOSES

Due to the broad spectrum of GSDs, when diagnosing patients with GSDs, it is often difficult to differentiate between certain types of GSDs. The clinical features of GSD I and GSD III are often similar. Hypoglycemia, which can be present in both types; however, it is often more severe in GSD type I. GSD III can also be distinguished from GSD I early in childhood by measuring liver enzyme, plasma CK concentrations, and plasma ketones (these are increased in GSD III as compared to GSD I). Patients with GSD I have a lactic acidosis, hyperuricemia and much higher levels of serum triglycerides and cholesterol as compared to GSD III. Patients with GSD VI and GSD IX have several similar clinical features as well, that makes it difficult to distinguish between both types. Checking for activity of phosphorylase and phosphorylase kinase can be used to diagnose either GSD VI or IX.

Another gluconeogenesis disorder that has several clinical features similar to GSD I, Fructose 1-6-bisphosphatase deficiency, has biochemical abnormalities that are similar to those in GSD I. Unlike GSD I, however, when glucagon administration is performed in the fed state, it elicits a brisk glycemic response. In patients with GSDs that affect muscle, there are other muscular disorders that must be considered as well, such as Duchenne muscular dystrophy, and secondary muscular disorders such as polymyositis.

## Approach to Diagnosis

Glycogen storage disease type Ia usually has an earlier presentation with hepatomegaly, hypoglycemia, lactic acidosis, hyperuricemia and deranged lipid profile with hypertriglyceridemia. GSD Ib additionally has neutropenia and frequent infections. Diagnosis can be confirmed by enzyme assay in liver biopsy (not available in India) or mutation analysis. Diagnosis of GSD type III is suspected in infants and children with fasting hypoglycemia and hepatomegaly and in older patients with progressive myopathy. Glucagon increases blood glucose after a carbohydrate meal but not after fasting. The liver biopsy shows typical glycogen storage and liver tissue can be assayed for the debrancher enzyme. Confirmation of a GSD IIIa diagnosis requires demonstration of enzyme deficiency in liver and muscle. Mutation analysis is available. Mutations in exon 3 at amino acid codon 6, [c.18\_19delGA (p.Gln6HisfsX20) and c.16C > T (p.Gln6X)], in combination with another mutation, are indicative of IIIb. The gene is located on chromosome 1p21.

Diagnosis of GSD type IV can be made by assaying the enzyme in a variety of tissues, including leukocytes, fibroblasts and amniocytes. Mutations in the gene *GBE1*, located on chromosome 3p14, are known to cause GSD type IV.

The ischemic exercise test can be useful for identifying patients with GSD type V; however, it is not specific to McArdle disease. Muscle biopsy shows subsarcolemmal lakes of PAS-positive material that is diastase positive. Myophosphorylase enzyme activity can be assayed in muscle tissue and demonstrated by histochemical stains on frozen sections from muscle biopsy. Genetic testing is available and is best to confirm diagnosis. The gene is located on chromosome 11q13.

The diagnostic approach for GSD type VII is similar to that used in McArdle disease. Muscle biopsy shows glycogen storage and the ischemic exercise test is positive. An enzyme analysis is necessary for a definitive diagnosis. The gene is located on chromosome 1q32.

Patients with GSD type IX can be diagnosed by deficient PhK activity in liver, erythrocytes or leukocytes. Genetic testing is also available. At diagnosis, individuals with liver PhK deficiency usually have elevated liver transaminases, and mildly elevated triglycerides and cholesterol. Liver glycogen content is markedly elevated in this GSD, similar to GSD III. The structure of glycogen is, however, abnormal in GSD III with an altered ratio of glucose-1-phosphate to glucose.

The relationship between the cognitive impairment and PhK deficiency is unclear. Electromyography and plasma lactate levels on forearm ischemic exercise tests are usually normal in these patients. Muscle biopsies show subsarcolemmal glycogen accumulation and marked reduction of PhK activity. Mutations causing muscle-specific PhK deficiency have been found in the gene encoding the alpha-subunit of PhK in muscle (PHKA1). Mutations causing liver-specific PhK deficiency are found in genes encoding both the alpha-subunit (PHKA2) and the gamma-subunit (PHKG2). Autosomal recessive PhK deficiency in both muscle and liver is linked to mutations in the gene encoding the beta-subunit (PhKB).

## MANAGEMENT

Treatment for GSD type I involves continuous nocturnal nasogastric feedings or uncooked cornstarch and should begin as soon as the diagnosis is suspected to maintain normal blood glucose levels and to prevent long-term complications. Nocturnal meals, in certain cases, may replace these nasogastric feedings. A number of enteral formulas and glucose polymers, such as uncooked cornstarch, can be used. Since infants may not adequately digest the starch, they may need to be given pancreatic enzymes. Older children should receive frequent daytime feedings of complex carbohydrates in addition to cornstarch to help maintain euglycemia and promote growth. Additionally, fructose and galactose intake should be restricted. Due to their high intake of carbohydrates, patients with GSD I should generally maintain a low-fat diet. The diet often needs supplementation with vitamins, specifically vitamin D, calcium and iron when there is a possibility of anemia. Secondary problems, such as hyperuricemia, hyperlipidemia and hepatic adenomas must be monitored and treated appropriately. In studies involving patients with small hepatic adenomas, percutaneous ethanol injection or transcatheter arterial embolization have been used as treatments. Liver transplantation or pre-emptive simultaneous liver plus kidney transplantation is required for some patients. Patients with GSD Ib have neutropenia and are at risk for life-threatening bacterial infections; these patients benefit from treatment with granulocyte colony-stimulating factor, but their spleen size, bone density and blood counts should be monitored.

Management of GSD type II, both infantile and late onset Pompe disease, has been greatly improved with the advent of enzyme replacement therapy using  $\alpha$ -glucosidase alfa and its approval for human use in 2006.

Glycogen storage diseases type III can be managed by cornstarch intake and a high protein diet. The latter is extremely useful due to intact gluconeogenesis. A ketogenic diet has also been shown to improve cardiomyopathy. Unlike GSD I, these patients do not have to restrict intake of sucrose and fructose. Frequent daytime meals rich in complex carbohydrates and proteins are usually sufficient to prevent hypoglycemia.

For patients with GSD type IV, there is no treatment except liver transplantation for those with progressive cirrhosis. This does not prevent nonhepatic complications of this disease.

Patients diagnosed with GSD type V can lessen symptoms and the chance of developing rhabdomyolysis by avoiding strenuous exercise. Exercise tolerance may be increased by fat and carbohydrate-rich meals as well as creatine and vitamin B<sub>6</sub> supplements taken prior to exercise.

Patients with GSD type VI can be managed with a high-carbohydrate and protein diet and frequent feeding to prevent hypoglycemia. There is no specific management other than avoidance of strenuous exercise for patients with GSD type VII. The use of a ketogenic diet has proven effective in some cases. Unlike in McArdle disease, eating before exercising worsens intolerance in Tauri disease.

Hypoglycemia in patients diagnosed with GSD type IX can be prevented by frequent daytime meals that are high in complex carbohydrates and protein. Growth may be improved by carbohydrate and protein supplementation, presumably by reducing the demand for gluconeogenesis and increasing insulin secretion. Individuals with muscle PhK deficiency may benefit from physical therapy and nutritional consult to optimize glucose concentrations based on level of activity. Malignant hyperthermia precautions should be taken.

## PREVENTION

Since GSDs are genetic disorders, there are no prevention measures that can be taken. In a known family history, prenatal diagnosis is possible allowing for treatment decision including not continuing an affected pregnancy. However, early diagnosis and treatment can greatly reduce the effects of GSDs on children.

## IN A NUTSHELL

1. Glycogen storage diseases are caused by the inability to synthesize or metabolize stored glycogen.
2. Glycogen storage diseases are categorized either chronologically by discovery or by the type of tissue involved, which primarily includes liver, muscle and cardiac tissue.
3. To date, over twelve glycogen metabolism disorders have been catalogued. Hepatic GSDs include types I, III, IV, VI, IX and XI. Muscle GSDs include types II, III, V, VII and IX. Hepatic glycogenoses cause hepatomegaly and fasting hypoglycemia, whereas the muscle glycogenoses can cause muscle weakness and cramps during exercise.
4. Glycogen storage diseases are most often diagnosed at a young age due to the early onset of symptoms.
5. Treatment for GSDs affecting the liver often involves maintaining glucose levels by regulating the release of glucose into the bloodstream. Treatment for GSDs that affect muscles often involves avoiding muscles weakness by limiting exercise or increasing protein intake.

## Chapter 3.15

# Pompe Disease

Mari Mori, Priya S Kishnani

Pompe disease (glycogen storage disease type II or acid maltase deficiency) is caused by a deficiency of acid alpha-glucosidase (GAA), leading to the deposition of glycogen predominantly in skeletal, smooth and cardiac muscles. GAA deficiency results in glycogen accumulation in lysosomes of all tissues, leading to progressive muscle destruction. It can present at various ages with variable symptoms. Advent of enzyme replacement therapy (ERT) with alglucosidase alfa has changed the natural history of the disease.

The disease is broadly categorized as infantile-onset Pompe disease (IOPD) and late-onset Pompe disease (LOPD). IOPD is further divided into two groups—*classic* and *atypical* (or *nonclassic*). Classic IOPD is characterized by generalized muscle weakness, hypotonia and hypertrophic cardiomyopathy. Atypical IOPD is characterized by slower progression, less severe to no cardiac involvement, and survival past 2 years of age. In IOPD, skin fibroblast GAA enzyme activity is below 1% of normal levels. LOPD is characterized by progressive muscle weakness with onset as early as age 1 year to as late as the sixth decade. Cardiac involvement, while more typical for classic IOPD, can be seen across the disease continuum. The cause of death in LOPD is typically respiratory failure.

Outcome of ERT is impacted by age and stage of the disease at treatment initiation, amongst other factors such as muscle fiber type, underlying mutation and defective autophagy. In this chapter, the new emerging natural history, limitations of ERT and pharmacologic and nonpharmacologic treatment approaches are reviewed. Multidisciplinary approach holds a key to an improved quality of life for patients with Pompe disease.

## EPIDEMIOLOGY

The prevalence of Pompe disease was previously estimated to be 1 in 40,000 livebirths, with varying prevalence depending on ethnicity. Founder effects in Taiwanese, Chinese and African population have been reported. New data from newborn screening (NBS) in Taiwan has shown an estimated prevalence of 1 in 18,108 across the disease spectrum.

## ETIOLOGY

Pompe disease is inherited in an autosomal recessive manner. The disease is caused by mutations in the GAA gene encoding GAA. The gene has been mapped on chromosome 17q21-q23. A founder mutation is found in the Chinese population causing IOPD, p.Asp645Glu; a common mutation found in African Americans is known, p.Arg854X; and a common mutation is known among Europeans, p.Gly309Arg. Genotype-phenotype correlation exists to some extent.

## PATHOGENESIS

Acid alpha-glucosidase digests glycogen to glucose. The enzyme is synthesized in the endoplasmic reticulum-Golgi complex and is transported to the lysosomes. It is a glycoprotein and goes through various modifications in the process. GAA activity is decreased in all tissues of patients with Pompe disease. Fibroblasts from IOPD have less than 1% residual activity, while those from LOPD have 1–40% residual activity.

Genotypes overall correlate with expression and activity of GAA. Over 200 disease causing mutations have been discovered and are available on the website: <http://cluster15.erasmusmc.nl/klgn/pompe/mutations.html>. The splice site mutation c.-32-13T > G is the most common mutation found in LOPD. It allows production of some normal protein leading to a less severe phenotype. The c.525delT and exon 18 deletion mutations are the most common mutations in the IOPD patients. Certain mutations correlate with cross-reactive immunological material (CRIM) status. CRIM-positive indicates detectable GAA protein, whereas CRIM-negative denotes absence of GAA protein (processed and unprocessed). The p.Arg854X stop mutation is a common mutation found in CRIM-negative patients. The majority of CRIM-negative patients are homozygous or compound heterozygous for nonsense, frame shift or exon-level deletions. In contrast, CRIM-positive patients have missense mutations, in-frame deletions or other milder mutations.

Muscle biopsy specimens show vacuolar myopathy. Both free and lysosomal glycogen accumulate in most tissues. Electron microscopy shows glycogen in lysosomal sacs, as well as in cytoplasm. It is important to recognize that histology may appear normal in LOPD depending on the site of biopsy. Enzyme testing is recommended when there is a strong clinical suspicion, as biopsy results can be reported as normal in LOPD. In these cases, positive acid phosphatase stain can be useful in making the diagnosis.

Compromised autophagy is evidenced both in humans and murine models. Autophagy debris build-up in muscle correlates with a decrease in muscle strength, mitochondrial dysfunction and muscular atrophy. Earlier treatment leads to less autophagic build-up.

## CLINICAL FEATURES

The severity of the Pompe disease reflects the residual activity of the acid alpha-glucosidase enzyme. The phenotype is also influenced by environment, diet, exercise and other genetic elements.

Infantile onset Pompe disease is the severe end of the spectrum of Pompe disease. Infants can manifest at birth or in the first few days to weeks of life with generalized hypotonia (**Figs 1A and B**) and muscle weakness. Classic IOPD is characterized by hypertrophic cardiomyopathy (**Fig. 1C**) and skeletal myopathy. Glycogen accumulation increases the muscle bulk (pseudohypertrophy), most prominent in the gastrocnemius muscles. Macroglossia is commonly seen. Infants with IOPD, if untreated, usually die before 2 years of age due to complications of cardiac and muscle weakness. Atypical IOPD present with slower progression with or without cardiac involvement. A natural history study of IOPD showed median onset of 2 months of age, diagnoses at 4.7 months, and death at 8.7 months. Central nervous system involvement in patients with IOPD includes anterior horn cells and brain stem nuclei. Treatment with ERT has changed the course of the disease. The oldest survivors are now 15 years of age. Long-term complications include persistent myopathy leading to a risk for cardiac arrhythmias, ptosis, hypernasal speech, swallowing dysfunction, poor anal sphincter tone, basilar artery aneurysm, and sensorineural hearing loss. Late-onset Pompe disease is characterized by muscle weakness manifesting from early childhood to late adulthood. Weakness predominates in truncal and proximal muscles, with lower extremities more involved than upper extremities. Respiratory muscles are also selectively affected. Respiratory insufficiency may be the presenting complaint and be associated with morning headache, exertional dyspnea, or sleep-disordered breathing. In LOPD, respiratory muscles are affected early and respiratory failure is usually the cause of death. LOPD can also present with ptosis, rigid spine syndrome, lingual weakness, and vascular complications such as basilar artery aneurysms, arrhythmias including Wolff-Parkinson-White (WPW)

**Figures 1A to C** Child with Pompe disease: Extreme floppiness. (A) Slip through appearance; (B) Ragged doll appearance; (C) Chest X-ray PA view shows presence of cardiomegaly. Source: Dr Neerja Gupta, AIIMS, New Delhi.

syndrome, intracranial aneurysms, lingual weakness, sensorineural impairment or oropharyngeal dysphagia due to bulbar weakness. Without treatment, LOPD patients tend to have an earlier mortality than the general population, with a median age of death at 55 years. LOPD patients receiving ERT tend to have stabilization of their disease process. Improvement is noted in some cases where treatment is initiated early.

## DIFFERENTIAL DIAGNOSIS

Both myopathy and cardiomyopathy can be seen in infants with cytochrome c oxidase deficiency (mitochondrial complex IV deficiency), but cardiomegaly is usually less marked than in IOPD. Autosomal dominant AMP-activated protein kinase deficiency caused by a heterozygous mutation in the *PRKAG2* gene, previously known as heart-specific phosphorylase b kinase deficiency, can present with massive cardiomegaly in infancy. Muscle weakness is usually minimal and muscle biopsy is essentially normal in this condition. Glycogen storage disease type IV due to branching enzyme (glycogen branching enzyme) deficiency can also present with infantile weakness and cardiomegaly. Danon disease, caused by either hemizygous or heterozygous mutation in the *LAMP2* gene, is another disorder that presents with cardiomyopathy.

Late-onset Pompe disease may simulate Duchenne muscular dystrophy in boys with calf pseudohypertrophy. Other metabolic myopathies of childhood include debrancher deficiency (GSD IIIa), brancher deficiency (GSD IV), and muscle phosphorylase b kinase deficiency (GSD V). GSD IV and V are often accompanied by hepatomegaly, fasting hypoglycemia, and elevated cholesterol and triglycerides. Disorders of fatty acid beta-oxidation including

carnitine uptake defect and mitochondrial respiratory chain defects also need to be considered. Lactic acidosis can be a clue to cytochrome c oxidase deficiency and other mitochondrial respiratory chain defects. LOPD is often misdiagnosed. It is important for clinicians to consider Pompe disease when diagnosing myopathic conditions.

## Approach to Diagnosis

The ACMG Practice Guidelines for Pompe disease offer a clear method for diagnosis in Pompe disease. The AANEM Consensus Treatment Recommendations for LOPD and Diagnostic criteria for LOPD (childhood and adult) also provide useful methodologies.

Infants presenting with floppy baby syndrome should be referred for a chest X-ray. A finding of massive cardiomegaly is highly suggestive of classic infantile Pompe disease and separates Pompe disease from other causes of floppy baby syndrome, such as spinal muscular atrophy type I (Werdnig-Hoffmann disease) and other metabolic or congenital myopathies. An electrocardiogram can further indicate the diagnosis, as IOPD patients typically have short PR intervals with tall QRS complexes. An echocardiogram would reveal a hypertrophic cardiomyopathy, occasionally with left ventricular outflow tract obstruction. Infantile patients will usually have high levels of creatine kinase (CK) (as high as 2,000 UI/L). CK is also elevated in other muscle diseases such as mitochondrial/respiratory chain disorders and several other glycogen storage diseases and muscular dystrophies.

Serum levels of CK, CK-MB, aspartate aminotransferase, alanine aminotransferase, lactate dehydrogenase are often elevated and can be useful clues to the diagnosis of Pompe disease, though nonspecific. Urinary Glc4, the predominant hexose tetrasaccharide

(Hex4) is a good biomarker of overall disease severity, as Glc4 levels increase as the level of skeletal muscle glycogen accumulation increases. In LOPD, weakness predominates in truncal and proximal muscles. Respiratory muscles, especially the diaphragm, may also be affected. Respiratory insufficiency may be the main complaint, accompanied by morning headache, exertional dyspnea, or sleep-disordered breathing. A pulmonary function test revealing a decrease in forced vital capacity from the upright to supine position can point to LOPD. These symptoms typically trigger the initial diagnosis of either limb girdle muscular dystrophy or polymyositis. LOPD can also present with WPW syndrome, various other rhythm disturbances, and dilation of the ascending aorta. Nerve conduction may show prevalent and abnormal myotonic discharges. CK levels are usually elevated.

Confirmation of the diagnosis of Pompe disease requires demonstration of reduced acid  $\alpha$ -glucosidase activity or presence of pathogenic mutations in the *GAA* gene. Acid  $\alpha$ -glucosidase activity can be measured on fibroblasts, muscle or blood. The activity can be measured most accurately in skin fibroblast. Blood-based assays including dried blood spots, lymphocytes and leukocytes are the least invasive methods. Histology and electron microscopy from muscle biopsy can offer further diagnostic support. It is important to recognize that normal muscle biopsy does not rule out LOPD.

*GAA* gene sequencing should be used for disease confirmation as well as for classification into IOPD/LOPD based on mutation. Genotyping can identify patients with pseudodeficiency who do not manifest as clinical disease. If p.Gly576Ser and p.Glu689Lys are found *in cis*, the combination is known to manifest pseudodeficiency. Genotyping is especially useful in NBS in order to limit false positives.

## MANAGEMENT

Alglucosidase alfa was approved in 2006 as ERT for patients with Pompe disease. Studies in IOPD showed that ERT improved survival, cardiac function, and growth/motor development in the population. Early treatment was found to be important for maximum efficacy. A subset of IOPD patients experienced a clinical plateau requiring an increase in ERT dose. IOPD survivors on ERT show a new phenotype, which provides insights into the disease process. Treatment response varies based on muscle fiber type, defective autophagy, degree of disease progression at the start of treatment, CRIM status, antibody response to ERT, and enzyme uptake into skeletal muscle. It has been shown that type II muscle fibers respond less to ERT compared to type I fibers. This explains why weakness in certain muscles, especially anterior tibialis, which contains abundant type II fibers, can persist in IOPD. Defective autophagy in Pompe disease leads to accumulation of autophagosomes containing recombinant enzyme. The autophagosome accumulation prevents glycogen clearance, especially in type II fibers, leading to the weakness of the anterior tibialis and other such muscles. Early treatment of IOPD is associated with improved skeletal muscle and respiratory functions. A study on the NBS program in Taiwan showed that early treatment of IOPD identified by NBS had better response to ERT than those identified based on clinical symptoms.

Cross-reactive immunological material-negative patients tend to respond to ERT poorly due to the development of persistently high sustained antibody titers (HSAT) to the recombinant enzyme. Even in CRIM-positive patients, HSAT can develop and compromise ERT. Immunomodulation with anti-CD20 monoclonal antibody, rituximab, methotrexate and gamma globulin eliminates the antibodies against recombinant enzyme in CRIM-negative patients, alleviating negative responses in ERT. Genotype of *GAA*

can predict CRIM status so that immunomodulation can be started simultaneously with ERT. It is crucial that immunomodulation is started before antibodies are formed. In mice, oral administration of recombinant enzyme was shown to reduce autoimmune response.

In LOPD, ERT has proven to reduce disease burden with improved walking distance, stabilized pulmonary function and neuromuscular deficits. Earlier treatment will be beneficial in patients with Pompe disease across the disease spectrum. Respiratory muscle strength training is being studied in individuals with Pompe disease.

High-protein low-carbohydrate diet and aerobic exercise have shown to lead to better function of LOPD. Caution is required to prevent overexertion as it leads to muscle damage. Muscle contraction can cause stress on the lysosomes and potentially leads to rupture of lysosomes, glycogen leakage into the cytoplasm and cell damage. Muscle contraction may, on the other hand, help glycogen clearance. Studies on optimal exercise are needed. A multidisciplinary approach is the key to overall improvement of quality of life in patients with Pompe disease.

Research on new therapeutic targets and immunomodulation is underway to maximize ERT efficacy. Specifically, the addition of mannose 6-phosphate residues, glycosylation independent lysosomal targeting are strategies being used to help recombinant enzyme better target the lysosomes. Chaperone-mediated therapy is another approach that aims to enhance delivery of the recombinant enzyme to lysosomes. Up-regulation of mannose-6-phosphate receptors is another promising treatment modality. A selective beta (2)-agonist clenbuterol effectively increased skeletal muscle cation-independent mannose-6-phosphate receptor expression and subsequent ERT efficacy in Pompe knockout mice. The addition of oral albuterol in patients on ERT also showed improvement in LOPD patients who were in clinical plateau on ERT. Gene replacement therapy is also in development.

## OUTCOME

Before availability of ERT, patients with IOPD died by 2 years of age. ERT leads to increased life expectancy in most IOPD patients. In surviving IOPD patients, long-term issues are being discovered. These include residual muscle weakness, hearing loss, osteopenia, dysphagia with risk for aspiration, risk of arrhythmias and hypernasal speech. In LOPD, ERT has resulted in stabilization of the disease.

## PREVENTION

Pompe disease is inherited in an autosomal recessive pattern. The disease can potentially be prevented by way of biochemical or molecular prenatal diagnosis. Genetic counseling is vital as part of prenatal testing. Early detection of Pompe disease by NBS enables early start of ERT and better outcome.

### IN A NUTSHELL

1. Pompe disease has aspects of glycogen storage, lysosomal storage and neuromuscular disease.
2. Clinical spectrum is wide but can be divided into two groups: IOPD and LOPD. IOPD consists of classic and atypical types. *Classic infantile Pompe disease* is currently the only term used with consensus.
3. Approval of intravenous alglucosidase alfa in 2006 as ERT changed the natural history of the disease and furthered our understanding of the disease.
4. Enzyme replacement therapy response varies based on muscle fiber type, defective autophagy, the degree of disease progression at the time of treatment initiation, CRIM status, antibody response to ERT, and insufficient enzyme uptake of skeletal muscle.
5. Investigational treatment modalities include noninvasive adjunctive therapies, immunomodulation to suppress or abrogate immune response, and new therapeutic targets.

## Chapter 3.16

# Mucopolysaccharidoses

Girisha KM

Mucopolysaccharidoses (MPSs) are a group of rare genetic disorders caused by deficiency of enzymes that catabolize glycosaminoglycans (GAGs). All are lysosomal enzymes and are coded by specific genes. They are biochemically characterized by accumulation of partially degraded GAGs in several tissues, urine and blood. Clinically, accumulation of GAGs leads to progressive cellular damage and causes multiple organ failures. The most commonly affected organs are brain, skeleton, eyes and viscera and they manifest with intellectual disability, cloudy cornea, organomegaly, coarse facies and dysostosis multiplex. Though individually rare, as a group MPSs represent common storage disorders with poor quality of life and they progress relentlessly. Early diagnosis and therapy not only help to decrease the severity of the disease, but also provide an opportunity to offer prenatal diagnosis to the affected families in their subsequent pregnancies.

## EPIDEMIOLOGY

The exact incidence of these disorders is not known, and the incidence of MPSs together is estimated to be around 3.5–4.5/100,000. The studies from India are scanty and prevalence data is not available from the community except for data from hospitals and laboratories. Our experience suggests that MPSI, MPSII and MPSIV are common varieties.

## ETIOLOGY

All MPSs are caused by mutations in specific genes. All genes encode lysosomal enzymes that are involved in degradation of GAGs (acid mucopolysaccharides). GAGs are complex carbohydrates made up of uronic acids, amino sugars and

neutral sugars. When the catabolizing enzymes are deficient, these GAGs (heparan sulfate, dermatan sulfate, chondroitin-4-sulfate, chondroitin-6-sulfate, keratan sulfate and hyaluronan, are components of proteoglycans present in cellular membranes and ground substance of connective tissue) get accumulated in tissues and excreted in urine. It is expected that mutations are spread throughout the entire gene and may be population specific. Except for Hunter syndrome (MPSII) which is an X-linked condition, all MPSs are inherited in autosomal recessive manner. **Table 1** lists all the MPSs and their causative genes. It may be noted that defects in the same gene can have varying severity of the same disease, best exemplified by MPSI.

## PATHOPHYSIOLOGY

The activity of enzyme is usually very low or absent in affected individuals. It is important to note that most of the MPSs exhibit a wide phenotypic variation, partly determined by the residual enzyme level and the mutant allele. This is best exemplified by the milder Scheie, intermediate Hurler-Scheie and severe Hurler syndromes, all caused by deficient activity of  $\alpha$ -L-iduronidase. Accumulated GAGs are responsible for the clinical, radiological and biochemical manifestations of the disease. Mental retardation is more likely when heparan sulfate catabolism is affected.

## CLINICAL FEATURES

Mucopolysaccharidoses are clinically distinct group of disorders with variable degree of growth failure, intellectual disability, coarse facial features, joint contractures, organomegaly, corneal clouding, glycosaminoglycanuria and dysostosis multiplex with onset in infancy and childhood. However, the classical subtypes may have quite distinct clinical features and often are easily recognized (**Figs 1A to C**).

*Hurler syndrome* is prototype for clinical features of MPSs presenting with three phenotypes of different severity. Similar features are shared by *Hunter syndrome* and *Sly syndrome* though *Sly syndrome* can present with hydrops fetalis. Coarse

**Table 1** Types of mucopolysaccharidoses, deficient enzymes and the genes

Type	Name	Enzyme	Gene	Glycosaminoglycans in urine
MPSI-H	Hurler syndrome	$\alpha$ -L-Iduronidase	IDUA	DS, HS
MPSI-HS	Hurler-Scheie syndrome	$\alpha$ -L-Iduronidase	IDUA	
MPSI-S (formerly MPSV)	Scheie syndrome	$\alpha$ -L-Iduronidase	IDUA	
MPSII	Hunter syndrome	Iduronate-2-sulfatase	IDS	DS, HS
MPSIII-A	Sanfilippo syndrome A	N-Sulfoglucosamine sulfohydrolase	SGSH	HS
MPSIII-B	Sanfilippo syndrome B	$\alpha$ -N-Acetylglucosaminidase	NAGLU	
MPSIII-C	Sanfilippo syndrome C	Heparan acetyl-CoA: $\alpha$ -glucosaminide-N-acetyltransferase	HGSNAT	
MPSIII-D	Sanfilippo syndrome D	N-Acetylglucosamine-6-sulfatase	GNS	
MPSIV-A	Morquio syndrome A	N-Acetylgalactosamine-6-sulfate sulfatase	GALNS	KS, CS
MPSIV-B	Morquio syndrome B	$\beta$ -Galactosidase	GLB1	KS
MPSVI	Maroteaux-Lamy syndrome	N-Acetylgalactosamine-4-sulfatase deficiency	ARSB	DS
MPSVII	Sly syndrome	$\beta$ -Glucuronidase	GUSB	DS, HS, CS
MPSIX	Natowicz syndrome	Hyaluronidase 1 deficiency	HYAL1	Unknown

Abbreviations: DS, dermatan sulfate; HS, heparan sulfate; KS, keratan sulfate; CS, chondroitin sulfate

facial features refer to constellation of large head with prominent forehead, flat nasal bridge, hirsutism, thick lips, large tongue and broad nasal tip. They often have noisy breathing (persistent nasal discharge). Skeletal changes include restricted joint mobility (contractures), dysostosis multiplex and short stature. In fact, the milder phenotype might present with isolated joint contractures (*Scheie syndrome*). Dysostosis multiplex (**Figs 2 and 3**) refers to the skeletal changes seen in MPSs and similar conditions (GM1 gangliosidosis and mucopolidoses): thick skull bones, widened sella turcica, broad oar-shaped ribs, bullet-shaped phalanges and metacarpals, irregular epiphyses and metaphyses, beaked or ovoid vertebral bodies (sloping of anterosuperior aspect best seen in lateral radiographic view of thoracolumbar spine) and broad diaphysis. Tapering of lower iliac wing is often evident and is a very useful radiological sign. Variable degree of intellectual disability is seen and is progressive. Other symptoms include loss of vision (pigmentary retinopathy), hearing loss, otitis media, obstructive sleep apnea, recurrent respiratory infections, hepatomegaly, splenomegaly, umbilical hernia, inguinal hernia and widely spaced teeth. Cardiac involvement results in regurgitation across valves, cardiomyopathy and arrhythmias. Hydrocephalus and spinal cord compressions can also occur. Subcutaneous nodules (pebble-like) are seen in MPSII often over back, neck and chest. Patients with severe forms of the disease usually succumb in the first or second decade of life.

Milder variants have a later age of onset (second half of first decade for MPSI-HS and second decade or beyond for MPSI-S) and intellectual functioning is better preserved (MPSI-S has almost normal intelligence).

*MPS-III* has more severe cognitive and neurological impairment than the somatic manifestations that may be very mild. Behavioral problems, developmental delay, dementia, poor social and communication skills are the predominant symptoms.

*MPS-IV* is unique in terms of skeletal involvement (with pronounced spondyloepiphyseal dysplasia, anterior-middle beaking of vertebral bodies, short ulna forming V-shaped angle

with lower end of radius and proximal pointing of metacarpals), joint laxity (striking at wrist joints), genu valgus, pectus carinatum and atlantoaxial instability (which can often lead to quadriplegia, if not fixed). Intellect is well preserved. However, corneal clouding is always seen. Milder forms of Morquio syndrome do exist and need to be carefully sought while dealing with children with skeletal dysplasia.

*MPS-VI* has somatic manifestations similar to that of MPSI, II and VII but differ from them in terms of preserved intellectual function. Other types of MPSs are rarely described in the literature.

## DIFFERENTIAL DIAGNOSIS

The other conditions which can have coarse facial features and dysostosis multiplex (of varying degree) are: aspartylglycosaminuria, fucosidosis, geleophysic dysplasia, GM1 gangliosidosis, mannosidosis, mucopolidoses, multiple sulfatase deficiency, sialidosis and Winchester syndrome. Coarse features may also be seen in hypothyroidism (with mild skeletal changes: epiphyseal dysgenesis and anterior beaking of vertebrae) and Coffin-Lowry syndrome. Cherry-red spots may be seen in GM1 gangliosidosis and sialidosis, whereas gum hypertrophy is commonly seen with GM1 gangliosidosis and mucopolidoses (I-cell disease). Extensive Mongolian spots also typify GM1 gangliosidosis. An elevated lysosomal enzyme in plasma is a clue for mucopolidoses. A thorough clinical, ophthalmic (for cherry-red spot in fundus) and radiographic evaluation, complemented by urine analysis for GAGs and oligosaccharides will usually help in differentiating these conditions. Final diagnosis will rest on enzyme assay or mutation testing. A referral to specialist may be warranted when the common tests do not lead to any definitive diagnosis. In consanguineous families, knowing the regions of homozygosity will provide useful differentials and may facilitate diagnosis. Of course, panels using next generation sequencing technology promise to be a cost-efficient way to test all these diseases with overlapping clinical features.

**Figures 1A to C** (A) Typical coarse facial features in a child with Hunter syndrome; (B). Mild coarsening in a 5-year-old boy with Hurler-Scheie syndrome; (C) Contractures of fingers in an adult with Hunter syndrome

**Figures 2A to E** Skeletal changes in mucopolysaccharidoses are termed dysostosis multiplex. (A) Skull shows thickened calvarium and widened sella turcica; (B) Pelvis shows straightening of lateral border of iliac bones with narrowing of lower part; (C) Metacarpals and phalanges resemble bullets (proximal narrowing of metacarpals and distal narrowing of phalanges; (D) Broad, oar-shaped ribs; (E) Beaking (flattened anterosuperior surface, arrow) of vertebrae

## APPROACH TO DIAGNOSIS

In all patients with clinical suspicion of MPS, detailed documentation of clinical findings guides one to the diagnosis. A three-generation pedigree will often help to determine the mode of inheritance. Important findings to note are intellectual disability, coarse facial features, joint contractures, corneal clouding and dysostosis multiplex.

A complete skeletal survey and urine analysis should be sought in all patients. Cloudy cornea is often detectable by simple torch light, but mild haziness and its absence should be confirmed by a slit lamp examination. Some important tips for diagnosis are: intelligence is normal in Maroteaux-Lamy syndrome, Morquio syndrome and Scheie syndrome, cornea are clear in Hunter syndrome and Sanfilippo syndrome, skin nodules are characteristic of Hunter syndrome, joint laxity and central beaking of vertebrae are seen in Morquio syndrome, and pronounced intellectual disability and behavioral problems in Sanfilippo syndrome.

Pattern of excretion of GAGs also gives a clue to the type of MPS. However, it should be noted that a spot urine test often gives false positive as well as false negative results. Enzyme assay to show the lack of activity (usually very low) and mutation analysis (sequencing of the causative gene) help to confirm the diagnosis and should be carried out in all cases. Enzyme assay is usually carried on leukocytes and rarely on cultured fibroblasts. The laboratory should always assay at least another enzyme as a control (for transport conditions). Presence of multiple sulfatase deficiency (which presents with similar phenotype) should also be sought by the laboratory performing the enzyme assay.

Presence of gum hypertrophy and cherry-red spot should be sought to consider MPS-like conditions. Carriers show a decreased activity of the enzyme, but enzyme assay is not usually the preferred method of carrier testing in clinical practice and mutations should

be confirmed in them before genetic counseling. When a sick child is first seen in the hospital, it is vital to carry out all the tests possible and preserve blood samples for DNA analysis at a later date to prevent the recurrence of the condition in the family.

## MANAGEMENT

A multidisciplinary approach is most crucial in the management of these patients and should involve the members from clinical genetics, genetic counseling, biochemistry, orthopedics, cardiology, neurology, neurosurgery, physical and occupational therapy, pulmonology, ophthalmology and otorhinolaryngology, whenever possible, considering the multisystem nature of these diseases. Early intervention can improve the life expectancy and quality of life in MPSs, which are otherwise life-threatening.

Hematopoietic stem cell therapy and enzyme replacement therapy are currently available definitive treatment options. Hematopoietic stem cell transplant if done early can halt the progression of the diseases and improve several manifestations of MPSI, MPSII, MPSVI and MPSVII. Life expectancy, quality of life, growth, respiratory symptoms, visceromegaly, joint mobility, hearing and vision improve with transplant. Hematopoietic stem cell transplant does not help to reduce the pre-existing neurological problems, skeletal and eye changes. Morbidity and mortality of transplant need to be considered against the natural history of the disease.

Enzyme replacement therapy has become available for MPS I, II and VI, and improves mobility, respiratory symptoms and organomegaly. Recently, enzyme replacement has been approved for Morquio syndrome as well. As administered enzymes do not cross blood-brain barrier, it is not effective in curing or preventing neurological manifestations. Currently, this is expensive and requires regular, lifelong administration and should be considered when hematopoietic stem cell transplant is not an option. It is often

**Figures 3A to D** Skeletal changes in Morquio syndrome are different from that seen in other mucopolysaccharidoses and are more like a spondyloepiphyseal dysplasia. (A) Atlantoaxial instability is a common complication; (B) Vertebrae show central anterior beaking; (C) Severe epiphyseal changes in head of femora; (D) Hands show V-shaped lower ends of radius and ulna (short ulna) and abnormal shaped metacarpals and phalanges

instituted before stem cell transplant and both may be combined for a better outcome. Enzyme replacement is being investigated for other MPSs too.

### OUTCOME AND COMPLICATIONS

All MPSs are progressive and affected children deteriorate gradually. The progression of the disease is difficult to predict and is complicated by the presence of a spectra of phenotype with mild to severe manifestations. If untreated, all are life-threatening and are associated with significantly low quality of life with delayed growth and development. Hydrocephalus and spinal cord compression are important neurological complications that need to be sought during follow-up visits. Other complications seen with these children include recurrent otitis media, impaired hearing, obstructive airway disease, valvular heart disease, cardiac arrhythmia, poor dental condition, carpal tunnel syndrome and progressive joint stiffness. Odontoid hypoplasia with resulting atlantoaxial instability and genu valgum need to be specifically looked for in patients with Morquio syndrome. A thorough preanesthetic evaluation is necessary for all the patients with MPSs before any surgery is contemplated.

### PREVENTION

Early diagnosis and appropriate treatment by a multidisciplinary team help to prevent the complications and decrease the morbidity of MPSs. As all of them carry a 25% risk of recurrence in the sibs of an affected child, prenatal diagnosis is an option for parents in their subsequent pregnancies. All the conditions can be diagnosed by enzyme assay in chorionic villus sample or cultured amniocytes. However, currently molecular methods are preferred over others for accurate prenatal diagnosis. The most crucial step for prenatal diagnosis is establishing a definitive diagnosis in the proband by enzyme assay and mutation testing which are now available at several centers in India. Newborn screening is now possible for most of these by high-performance liquid chromatography or tandem mass spectrometry and holds promise for early diagnosis. Early institution of therapy in the asymptomatic period can prevent progression of the disease in the child. This also helps to prevent recurrence of the condition in the family. Genetic counseling is essential for all families and extended family members, especially in view of widespread consanguineous marriages in several parts of our country.

### IN A NUTSHELL

1. Mucopolysaccharidoses represent a group of lysosomal storage disorders with defective metabolism of GAGs.
2. All of them are caused by enzyme deficiencies and have mutations in different genes.
3. Hunter syndrome is an X-linked condition and others exhibit autosomal recessive inheritance.
4. All MPSs exhibit varying degree of coarse facial features and dysostosis multiplex. Coarse features and dysostosis are seen in few other conditions as well. Morquio syndrome, however, is distinct with predominant skeletal dysplasia.
5. Multidisciplinary supportive care is currently the mainstay of therapy. Hematopoietic stem cell transplantation and enzyme replacement therapy have the potential to limit the manifestations of the disease if instituted early in select MPSs.
6. Genetic counseling is an important part of management of these conditions. Prenatal diagnosis is now possible in India either by enzyme assay or by molecular methods (preferred) for all these conditions.
7. Newborn screening and early intervention are promising new developments for these conditions.

## Chapter 3.17

# Approach to Hypoglycemia

Meenakshi Bothra, Vandana Jain

### DEFINITION

The operational threshold for hypoglycemia is defined as the concentration of plasma or whole blood glucose at which clinicians should consider intervention, based on the evidence currently available in literature. Operational definition of hypoglycemia in neonates is taken as blood glucose value less than 40 mg/dL (plasma glucose level less than 45 mg/dL). In older infants and children, a whole blood glucose concentration of less than 50 mg/dL (10–15% higher for serum or plasma) is considered as hypoglycemia, while in children with severe acute malnutrition (SAM), the cut-off is taken as blood glucose value of less than 54 mg/dL.

### EPIDEMIOLOGY

The estimated incidence of symptomatic hypoglycemia in newborns is 1–3/1,000 livebirths. It is more common in premature and small for gestational age (SGA) neonates. The incidence of hypoglycemia in children older than 6 months in a large urban critical care department at Philadelphia, USA was noted to be 3.4 per 10,000 births. Ketotic hypoglycemia has a frequency of 1/10,000–15,000 births.

### NORMAL GLUCOSE HOMEOSTASIS

Plasma glucose is derived from intestinal absorption of dietary carbohydrates or endogenous glucose production by either glycogenolysis or gluconeogenesis. Glucose is transported into the cellular compartment by different glucose transporters. In neonates, glucose homeostasis is regulated by a balance between glucose utilization and production, controlled by the action of insulin and the counter-regulatory hormones, like growth hormone, cortisol, glucagon and catecholamines. Normally, there is an abrupt fall in the blood glucose concentrations within 1–2 hours after birth. Over the first few days of life, with establishment of regular enteral feeding and continued maturation of hepatic gluconeogenesis, blood glucose levels further stabilize.

Plasma glucose concentrations are normally maintained within a relatively narrow range, in the fasting state with transient excursions after a meal by a network of hormones, neural signals, and substrate effects that regulate endogenous glucose production and glucose utilization. Between meals and during fasting, plasma glucose levels are maintained by endogenous glucose production, hepatic glycogenolysis, and hepatic (and to a small extent, renal) gluconeogenesis. Hepatic glycogen stores are usually sufficient to maintain plasma glucose levels for approximately 8 hours. This time period can be shorter if glucose demand is increased by exercise or if glycogen stores are depleted by starvation. Among the factors regulating blood glucose level, insulin plays a dominant role. As plasma glucose level decreases, insulin secretion decreases. This results in decrease in glucose utilization in peripheral tissues, increase in hepatic glycogenolysis and gluconeogenesis, and increase in lipolysis and proteolysis. Among the counter-regulatory hormones, glucagon, which stimulates hepatic glycogenolysis, is the most important, and is the second defense against hypoglycemia. Epinephrine, which stimulates hepatic glycogenolysis and gluconeogenesis is the third defense against hypoglycemia.

## ETIOLOGY

### Transient Hypoglycemia

The important causes of transient hypoglycemia in neonates are listed in **Box 1**. In the preterm and SGA babies, there are inadequate stores of glycogen, protein, and fat needed to provide the substrates required to generate energy. In addition, their enzyme systems for gluconeogenesis may not be fully developed. Transient hypoglycemia usually resolves within 48–72 hours after birth. Transient hyperinsulinemic hypoglycemia (lasting for weeks to months) is occasionally seen in asphyxiated, SGA and premature newborns.

#### BOX 1 Etiology of transient hypoglycemia in neonates

- Prematurity
- Small for gestational age
- Infant of diabetic mother
- Discordant twin
- Birth asphyxia
- Infant of toxemic mother.

Maternal gestational or insulin-dependent diabetes mellitus represents one of the most common conditions responsible for transient hypoglycemia in neonates. It is also the most common cause of hypoglycemia posing significant risk of permanent brain damage. These babies are usually born large for date and plethoric, and may have other metabolic abnormalities like hypocalcemia and hypomagnesemia. The most plausible explanation for hypoglycemia in these neonates is the Pederson's maternal hyperglycemia, fetal hyperinsulinemia hypothesis. The high insulin, low glucagon and low epinephrine levels in these babies inhibit the endogenous glucose production, thus predisposing them to hypoglycemia. Babies born to diabetic mothers with good glycemic control are less likely to develop neonatal hypoglycemia.

### Persistent/Recurrent Hypoglycemia

The causes of persistent hypoglycemia in infancy are listed in **Box 2**.

#### Endocrine Causes

Hyperinsulinism is the most common cause of persistent hypoglycemia in early infancy. Hyperinsulinemic infants may be macrosomic at birth. In these babies, plasma insulin concentration is inappropriately elevated at the time of documented hypoglycemia. The age at which a baby becomes symptomatic depends on the degree of hyperinsulinemia, with severely affected babies becoming hypoglycemic immediately after birth and the less severely affected ones manifesting later (up to the age of 18 months). The hyperinsulinemic babies who are less severely affected may manifest with hypoglycemia within 4–8 hours of fasting.

*Persistent hyperinsulinemic hypoglycemia of infancy* It is a heterogeneous group of disorders, previously known by different names like nesidioblastosis and congenital hyperinsulinism. Persistent hyperinsulinemic hypoglycemia of infancy (PHHI) can be due to either diffuse or focal  $\beta$ -cell hyperplasia, of which, the focal type has a better prognosis. Both autosomal recessive and dominant forms of PHHI have been described. The autosomal recessive form is much more common in the Arabic and Ashkenazi Jewish population, probably due to the high rates of consanguinity. Mutations in the genes encoding for the pancreatic K-ATP channel, glutamate dehydrogenase (GDH), glucokinase (GCK), L-3-hydroxyacyl-coenzyme A dehydrogenase (HADH), hepatocyte nuclear factor 4 $\alpha$  (HNF4 $\alpha$ ), monocarboxylate transporter (MCT1)

**BOX 2 Etiology of persistent hypoglycemia in infancy and childhood**

- Endocrine causes
  - Persistent hyperinsulinemic hypoglycemia of infancy (PHHI)
  - Panhypopituitarism, isolated growth hormone deficiency
  - Adrenocorticotrophic hormone deficiency, Addison disease
  - Epinephrine deficiency
- Glycogenolysis and gluconeogenesis disorders
  - Glycogen storage diseases (GSD) types 1, 3, 6, 9, 0
  - Fructose-1,6-diphosphatase deficiency
  - Pyruvate carboxylase deficiency
  - Galactosemia
  - Hereditary fructose intolerance
- Fatty acid oxidation disorders
  - Primary or secondary carnitine deficiency
  - Carnitine palmitoyltransferase-1 or 2 deficiency
  - Carnitine translocase deficiency
  - Very long-, long-, medium-, short-chain acyl CoA dehydrogenase deficiency
- Amino acid and organic acid disorders
  - Maple syrup urine disease
  - Propionic acidemia
  - Methylmalonic acidemia
  - Tyrosinosis
  - Glutaric aciduria
- Systemic disorders
  - Sepsis, shock
  - Neoplasms secreting insulin-like growth factor II
  - Malnutrition, malabsorption, diarrhea
  - Burns, postsurgical
  - Pseudohypoglycemia (leukocytosis, polycythemia)
  - Excessive insulin therapy in type 1 diabetes mellitus
  - Factitious
  - Falciparum malaria

and uncoupling protein 2 (UCP2) as shown in **Figure 1**. Out of the above, mutations in the genes coding for SUR or KIR6.2 that prevent K-ATP channel from being open, result in increased insulin secretion, are the most common and the genes responsible are *ABCC8* and *KCNJ11* on chromosome 11p15.1. One form of autosomal dominant PHHI is due to an activating mutation in GCK. The common mutations associated with hyperinsulinemia have been shown in **Figure 1**.

Hyperinsulinemic hypoglycemia is also seen in 50% of patients with *Beckwith-Wiedemann syndrome*, which is caused by mutations in the chromosome 11p15.5 region close to the genes for insulin, *SUR*, *KIR6.2*, and insulin-like growth factor 2 (IGF-2). These babies also have omphalocele, gigantism, macroglossia, microcephaly, and visceromegaly with or without hemihypertrophy. Hyperinsulinemia in these babies is due to diffuse pancreatic islet cell hyperplasia. These children are predisposed to develop certain tumors like Wilms tumor, hepatoblastoma, adrenal carcinoma, gonadoblastoma and rhabdomyosarcoma.

Hyperinsulinemic hypoglycemia presenting in children above 5 years of age is usually due to *islet cell adenomas*, which may be associated with hyperparathyroidism and pituitary tumors, as a part of multiple endocrine neoplasia type 1 (MEN 1, Wermer syndrome). Prolonged fasting for 24–36 hours usually provokes hypoglycemia in these patients.

Hypoglycemia is seen in about 20% of patients with *panhypopituitarism* and combined or isolated adrenocorticotrophic hormone (ACTH) or growth hormone deficiency. Male babies with panhypopituitarism may have micropallus due to coexistent gonadotropin deficiency. Cholestatic jaundice is commonly seen among these babies.

Hypoglycemia can also be seen in children with *adrenal insufficiency*, as seen in congenital adrenal hyperplasia (CAH), bilateral adrenal hemorrhage, familial glucocorticoid deficiency, adrenal hypoplasia or congenital absence of the adrenal glands. Depending on the underlying adrenal disorder, some of these babies may have associated hyperpigmentation, dyselectrolytemia, hypertension, salt wasting or ambiguous genitalia.

### Metabolic Causes

Inborn errors in glycogen synthesis or breakdown, gluconeogenesis and fatty acid oxidation can present with hypoglycemia. Several hours of fasting are needed for hypoglycemia to manifest. These disorders usually present in later infancy when feeding interval has increased and the infant has started sleeping through the night, or during intercurrent illness with reduced oral intake. Some of the major inborn errors of metabolism presenting with hypoglycemia are discussed briefly in the following section.

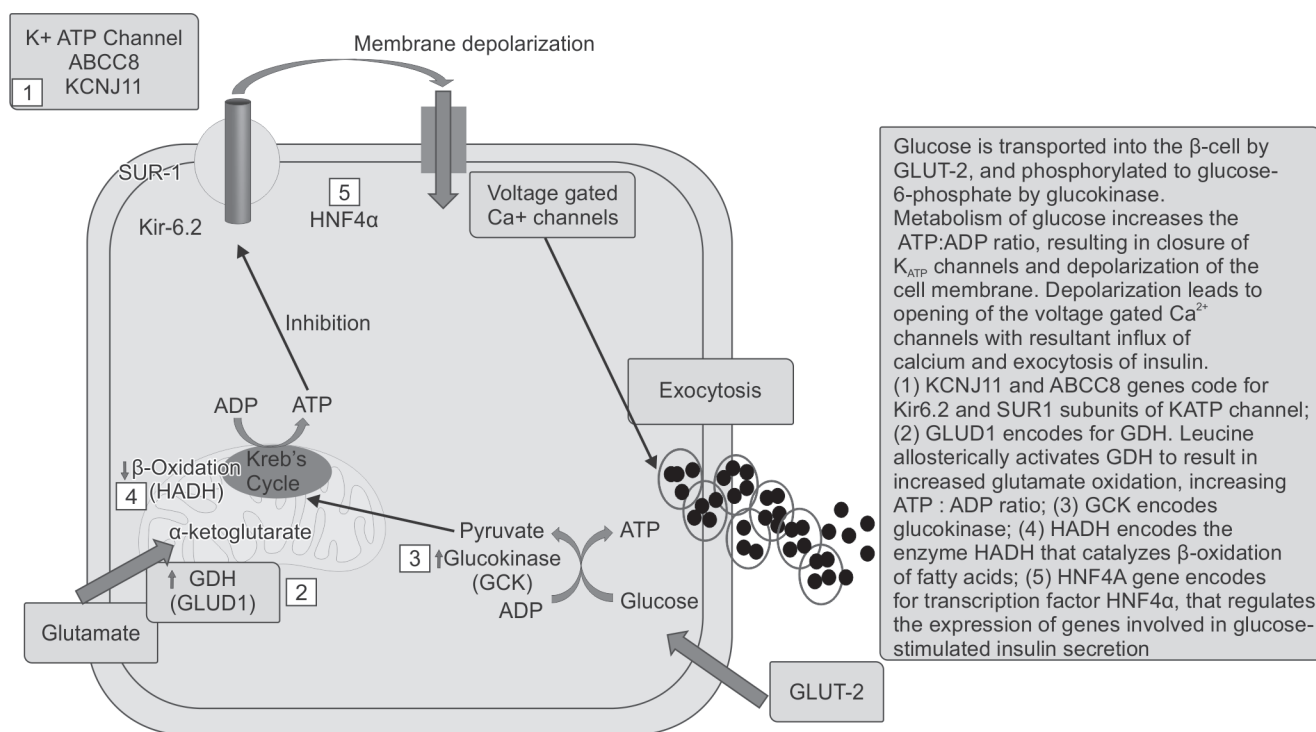

**Ketotic hypoglycemia** It is the most common form of childhood hypoglycemia and usually presents with episodes of hypoglycemia in early morning, between 18 months and 5 years of age. It usually undergoes spontaneous remission by the age of 8–9 years. Hypoglycemic episodes occur during periods of intercurrent illness when food intake is limited. Ketotic hypoglycemia may be due to a defect in any of the steps involved in protein catabolism, oxidative deamination of amino acids, transamination, alanine synthesis or alanine efflux from muscle. These children are usually smaller than other children of their age, and may have a history of transient neonatal hypoglycemia. These children have been found to have markedly reduced plasma alanine (a major gluconeogenesis precursor) concentrations after an overnight fast. In branched chain ketonuria (maple syrup urine disease) also, hypoglycemia is due to limited availability of alanine.

**Glycogen storage disease (GSD)** Type I (most common), III and VI may present with fasting hypoglycemia. These babies may have lethargy or hypoglycemic seizures early in the morning due to relatively longer intervals between feeding at night. These children usually have growth failure and hepatomegaly due to excessive deposition of glycogen in liver.

**Defects in fatty acid or carnitine metabolism** These may be associated with fasting hypoglycemia, as fatty acids are substrates for gluconeogenesis. Fasting hypoglycemia with hepatomegaly, cardiomyopathy and hypotonia is seen in long- and medium-chain fatty acid coenzyme-A dehydrogenase deficiency (LCAD and MCAD). Patients with acyl CoA dehydrogenase deficiency may present with a Reye-like syndrome, hypotonia, seizures and a characteristic acrid odor. Hypoglycemia without ketonuria can also be seen as an adverse effect of sodium valproate, which can also lead to a Reye-like syndrome.

**Galactosemia** is caused by the deficiency of the enzyme galactose-1-phosphate uridyl transferase (GALT). Deficiency of UDP-galactose-4-epimerase also has a similar presentation. Affected infants present with vomiting, diarrhea, jaundice and hepatomegaly in addition to hypoglycemia. *E. coli* sepsis commonly occurs in affected infants. Cataracts, liver dysfunction, renal tubular defects, intellectual impairment and ovarian failure are other clinical manifestations. Diagnosis is suspected by presence of non-glucose-reducing substance in urine and confirmed by assay for GALT and epimerase enzymes. Management consists of dietary galactose restriction.

**Hereditary fructose intolerance** is caused by deficiency of the enzyme fructose-1-phosphate aldolase and manifests only after inclusion of fructose in the diet. In infants fed with fructose or sucrose containing formulae, there is acute postprandial hypoglycemia along with vomiting and abdominal distension. The

**Figure 1** Regulation of insulin secretion by pancreatic  $\beta$ -cell, and mutations associated with persistent hyperinsulinemic hypoglycemia of infancy (PHHI)  
 Abbreviations: GDH, glutamate dehydrogenase, HADH, hydroxyacyl-coenzyme A dehydrogenase; HNF4 $\alpha$ , hepatocyte nuclear factor 4 $\alpha$ ; MCT1, monocarboxylate transporter.

hypoglycemia is caused by an acute inhibition of glycogenolysis and gluconeogenesis by the accumulation of fructose-1-phosphate. As the affected children become symptomatic after eating sweet food items (containing fructose or sucrose), they gradually develop aversion to sweets.

**Phosphoenol pyruvate carboxykinase deficiency** This rate-limiting gluconeogenic enzyme deficiency is associated with severe fasting hypoglycemia soon after birth. There is fatty infiltration of organs like liver, due to increased synthesis of acetyl CoA, which becomes available for fatty acid synthesis.

**Glucose transporter 1 and 2 deficiency** Those with glucose transporter 1 (GLUT 1) deficiency may present with seizures and are found to have low cerebrospinal fluid (CSF) glucose and lactate concentrations, despite normal plasma glucose, while those with GLUT-2 deficiency may present with hypoglycemia due to defective release of glucose from liver and its impaired tubular reabsorption, hepatomegaly, galactose intolerance and renal tubular dysfunction (Fanconi-Bickel syndrome).

### Systemic Disorders

In *severe sepsis*, especially in neonates or *severely malnourished* babies, hypoglycemia is seen due to impaired gluconeogenesis as well as diminished caloric intake. Polycythemia (hematocrit >65%) is also one of the important causes of hypoglycemia among neonates. In tropical countries, *falciparum malaria* is also an important cause of hypoglycemia.

## CLINICAL FEATURES

A detailed history including the age at onset, birth weight, temporal relation of hypoglycemia to meals, history of maternal diabetes, parental consanguinity, family history of unexplained infant deaths

or siblings with similar presentation should be enquired. Most of the babies presenting in the 1st week of life have the transient form of neonatal hypoglycemia, as discussed earlier. A large for date baby, born to a nondiabetic mother suggests hyperinsulinemic hypoglycemia of infancy. Hypoglycemia occurring shortly after meals is commonly seen in galactosemia or hereditary fructose intolerance, while symptoms due to hypoglycemia occurring 6 hours or more after meals points toward an underlying disorder of gluconeogenesis or autosomal dominant forms of hyperinsulinemic hypoglycemia. Hypoglycemia only on prolonged fasting (usually for 24–36 hours) is seen in fatty acid oxidation defects. Enquiry should also be made about the ingestion of toxins like alcohol or salicylate and inadvertent or deliberate ingestion of oral hypoglycemic drugs or use of excessive insulin in a known diabetic or nondiabetic child. Possibility of errors in dispensing or administering medicines should also be considered.

Symptoms and signs due to hypoglycemia per se, seen especially in older children have been mentioned in **Box 3**. However, in the neonatal period and infancy, there can be some atypical features like jitteriness or tremors, apathy, cyanosis, convulsions, apnea or lethargy. Characteristic clinical features of some of the earlier

### BOX 3 Clinical features of hypoglycemia

#### Features of sympathetic overactivity

- Due to release of adrenaline
- Usually seen with rapid decline in blood glucose
- Anxiety, perspiration, palpitations, pallor and tremulousness.

#### Neuroglycopenic symptoms

- Due to decreased cerebral glucose utilization
- Seen with slow decline in blood glucose or in prolonged hypoglycemia
- Headache, mental confusion and visual disturbances.

described disorders and associated abnormalities have already been mentioned in the etiology section.

On physical examination, presence of hepatomegaly points towards the possibility of an underlying glycogenolytic or gluconeogenic enzyme deficiency. The presence of a microphallus (in males) and neonatal jaundice may be clues to the presence of hypopituitarism in neonates and infants, while short stature or a subnormal growth velocity may be a useful clue in older children.

## INVESTIGATIONS

The first step in determining the underlying etiology of hypoglycemia is the collection of *critical sample*, comprising of certain investigations on blood and urine at the time of documented hypoglycemia, which may have occurred spontaneously or had to be *provoked* by supervised fasting for several hours. The investigations done as a part of *critical sample* include simultaneous measurement of blood glucose, insulin, cortisol, ketones and free fatty acids (FFAs) in the same sample at the time of clinically manifested hypoglycemia as listed in **Table 1**. Blood ketone level estimation is not readily available, so detection of urine ketones using dipsticks can be used as a surrogate marker. The algorithmic approach that may be followed in infants and children with hypoglycemia is shown in **Flow chart 1**.

In children with PHHI, the insulin level is usually more than 5–10  $\mu\text{U/mL}$  and the insulin ( $\mu\text{U/mL}$ ): glucose (mg/dL) ratio is more than 0.4. In addition, plasma insulin-like growth factor binding protein-1 (IGFBP-1), ketones and FFA levels are low and there is no acidosis. The glycemic response to glucagon at the time of hypoglycemia shows a brisk increment in blood glucose by 40 mg/dL or more, because the glycogenolytic mechanisms are

intact. 18F-labeled L-dopa positron emission tomography (PET) scanning is highly accurate in distinguishing the focal from the diffuse form of PHHI.

C-peptide levels can be measured in cases where exogenous administration of insulin is suspected as the cause for hyperinsulinemic hypoglycemia. C-peptide will be low or absent in such cases of factitious hypoglycemia.

The presence of reducing substances in urine can be detected by Benedict's test. It helps to diagnose fructose intolerance and galactosemia. Presence of nonglucose-reducing sugar in the urine points towards galactosemia. The absence of ketonemia or ketonuria suggests hyperinsulinemia, defect in fatty acid oxidation, galactosemia or hereditary fructose intolerance as the underlying etiology.

Hypoglycemia with ketonemia and ketonuria in children between 1.5 years and 5 years is most likely to be ketotic hypoglycemia, especially if hepatomegaly is absent. In susceptible individuals, fasting usually provokes a hypoglycemic episode with ketonemia and ketonuria within 12–18 hours.

In fatty acid oxidation defects, plasma carnitine levels are low, ketones are not present in urine, but dicarboxylic aciduria is present. Fasting to induce hypoglycemia is contraindicated if a fatty acid oxidation defect is suspected. Tandem mass spectrometry (TMS), urinary gas chromatography mass spectrometry (GCMS) and molecular methods are useful in diagnosis.

In phosphoenol pyruvate carboxykinase deficiency, liver, kidney and myocardium demonstrate fatty infiltration. Atrophy of the optic nerve and visual cortex may be noted. Hypoglycemia may be profound. A supervised fasting may be used to provoke hypoglycemia. Lactate and pyruvate levels in plasma are normal,

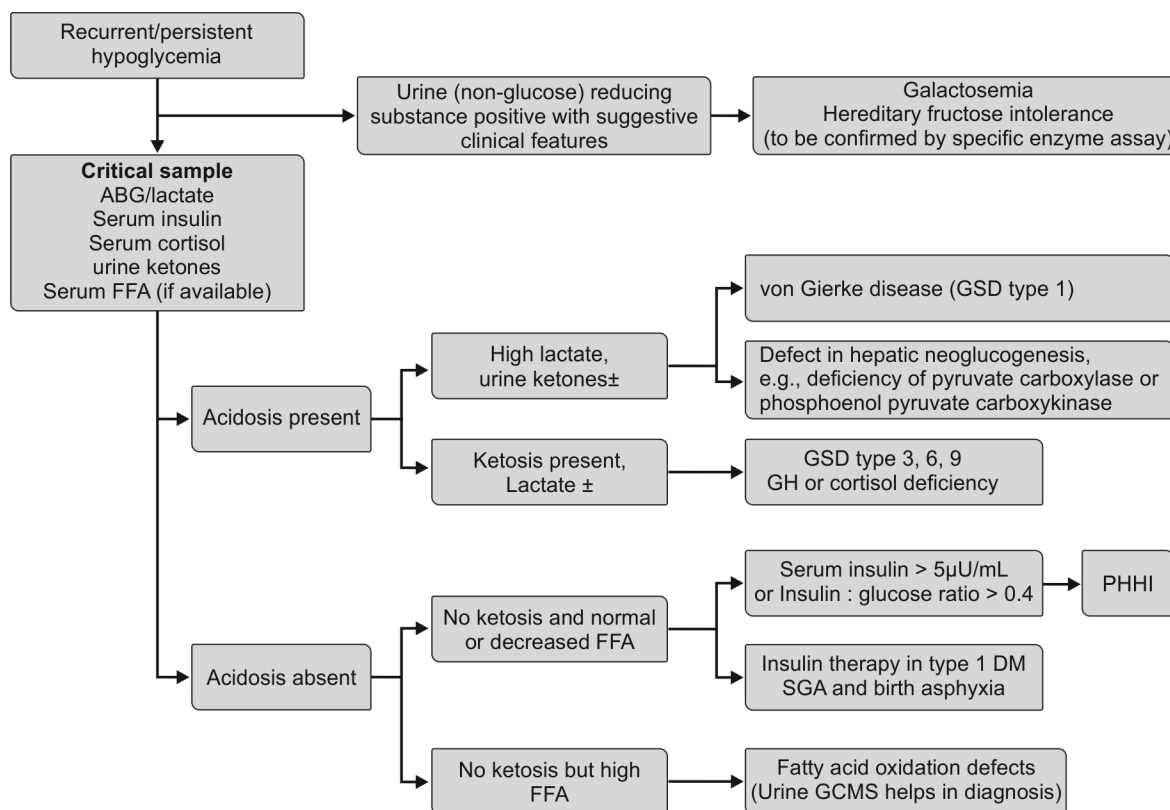

**Table 1** Investigations for determining the etiology of hypoglycemia using the critical sample

Investigation	Cut-off beyond which abnormal	Underlying disease, if abnormal
Glucose*	<40 mg/dL (newborns), <50 mg/dL (older children) <i>Glucagon challenge test:</i> Rise by $\geq 40$ mg/dL, 30 min after giving glucagon 50 $\mu\text{g}$ /kg (maximum 1 mg) IV or IM	Confirmation of hypoglycemia  Hyperinsulinemic state with adequate hepatic glycogen stores and intact glycogenolytic enzymes
Insulin*	Plasma insulin $> 2$ $\mu\text{U/mL}$ or Insulin ( $\mu\text{U/mL}$ ): glucose (mg/dL) $> 0.4$ Plasma insulin $> 100$ $\mu\text{U/mL}$	Endogenous hyperinsulinemia  Suspect factitious cause (exogenous insulin injection)
Cortisol*	<10 $\mu\text{g/dL}$	Adrenal insufficiency or pituitary disease or both
Ketones* (urine ketones may be used as surrogate if blood ketones unavailable)	Plasma $\beta$ -hydroxybutyrate: $< 2.0$ mmol/L and/or urine ketones absent Plasma $\beta$ -hydroxybutyrate: $> 2.0$ mmol/L and/or urine ketones present	Hyperinsulinemia or fatty acid oxidation defect  Inborn error of glycogen metabolism, or defective gluconeogenesis
Free fatty acids <sup>#</sup>	Plasma-free fatty acids $< 1.5$ mmol/L	Hyperinsulinemia
Growth hormone <sup>#</sup>	$< 5$ ng/mL	Adrenal insufficiency or pituitary disease or both
Thyroxine/TSH <sup>#</sup>	Low free thyroxine in the setting of a low or inappropriately normal TSH level	Hypopituitarism
Lactate <sup>#</sup>	$> 1.6$ mmol/L or 14.4 mg/dL	Organic acidemias, GSD type 1, fructose-1,6-diphosphatase deficiency
Uric acid <sup>#</sup>	$> 5$ –7 mg/dL	von Gierke disease (GSD type 1)
Ammonia <sup>#</sup>	$> 100$ –200 $\mu\text{m}$	Activating mutation of glutamate dehydrogenase

Note: \*To be done in all cases of undiagnosed persistent/recurrent hypoglycemia.

#May be done depending on the clinical scenario and/or availability.

Abbreviations: TSH, thyroid-stimulating hormone; GSD, glycogen storage disease.

**Flow chart 1** An algorithmic approach to persistent/recurrent hypoglycemia in infants and children

but a mild metabolic acidosis may be present. Confirmatory diagnosis requires enzymatic determination in liver biopsy material.

If hepatomegaly is present along with hypoglycemia, glycogen storage disease is suspected. One should investigate for the presence of hyperlipidemia, acidosis, hyperuricemia and response to glucagon in the fed and fasted states. Definitive diagnosis may require liver biopsy with estimation of the enzyme activity or molecular diagnosis.

Adrenal insufficiency is a close mimicker of ketotic hypoglycemia. So, plasma cortisol levels should be determined at the time of documented hypoglycemia, which if low, should be followed by definitive tests of pituitary-adrenal function.

## TREATMENT

The treatment comprises of:

- The management of hypoglycemic episode, and
- Treatment based on the underlying etiology of hypoglycemia.

### Treatment of Acute Symptomatic Neonatal or Infantile Hypoglycemia

This includes intravenous (IV) administration of 2 mL/kg of 10% dextrose, followed by a continuous infusion of glucose at 6–8 mg/kg/min, adjusting the rate to maintain blood glucose levels in the normal range and gradually decreasing and stopping the IV fluids, if the child remains euglycemic. Asymptomatic babies may be offered a feed and the blood glucose rechecked after 30–60 minutes. If the blood glucose becomes normal, frequent feeding along with blood glucose monitoring is continued. The management of persistent neonatal or infantile hypoglycemia includes increasing the rate of

IV glucose infusion to 10–15 mg/kg/min and titrating the rate of infusion according to the blood glucose values. A central venous access should be established in these infants as it helps in ensuring uninterrupted infusion. Also, dextrose solutions of strength more than 12.5% should not be infused through peripheral lines. If the baby is tolerating feeds, attempts should be made to gradually decrease IV glucose infusion and start baby on oral/orogastric/nasogastric fortified feeds.

Hypoglycemia may recur in 10–15% of infants after adequate treatment. Recurrence is more common if there is disruption in the glucose infusion due to mechanical causes, or IV fluids are extravasated or discontinued too rapidly before oral feeds are tolerated.

### Treating Hyperinsulinemia

If hyperinsulinemia is present, medical management with diazoxide (5–15 mg/kg/day in 2–3 divided doses) and somatostatin analogs like octreotide is tried first. An adequate trial of diazoxide is considered as its use in maximal dose for at least 5 days. The adverse effects of diazoxide include hirsutism, edema, nausea, hyperuricemia, electrolyte disturbances, advanced bone age and hypotension with prolonged use. Addition of thiazide with diazoxide helps in reducing edema and dyselectrolytemia. Octreotide is used as the second-line therapy in infants who do not respond to or tolerate diazoxide. This is administered subcutaneously every 6–12 hourly in doses of 5–25 µg/kg/day. Adverse effects include poor growth due to inhibition of growth hormone release, pain at the injection site, vomiting, diarrhea and hepatic dysfunction. There are anecdotal reports on the use of calcium channel blockers. The target blood glucose level in these babies is between 50 mg/dL and 100 mg/dL. Hyperglycemia is to be avoided as it will further stimulate insulin secretion and would lead to rebound

hypoglycemia. Long-term medical therapy without pancreatic resection may be tried if blood glucose is maintained in the normal range, because some children have a spontaneous resolution of the hyperinsulinemic hypoglycemia. However, this approach should be balanced against the risk of hypoglycemia-induced central nervous system (CNS) injury and the toxicity of drugs. In infants who are refractory to medical management, subtotal or focal pancreatectomy may be needed. Total pancreatectomy is not advocated, owing to the risks of surgery, permanent diabetes mellitus and exocrine pancreatic insufficiency.

### Ketotic Hypoglycemia

The treatment of ketotic hypoglycemia consists of frequent feedings with a high-protein and carbohydrate diet. During intercurrent illnesses, urinary ketones (which usually precede hypoglycemia) should be monitored. In the presence of ketonuria, if the child is accepting orally, liquids of high carbohydrate content should be offered to the child. However, if the oral intake is poor, IV fluids should be started. In children with fatty acid oxidation defects, carnitine supplementation has been found to be beneficial. In phosphoenol pyruvate carboxykinase deficiency, avoidance of periods of fasting through frequent feedings rich in carbohydrate should be helpful, because glycogen synthesis and breakdown are intact. In infants and children with glycogen storage diseases as

the underlying cause of hypoglycemia, frequent feeds including nocturnal feeds is recommended. Use of cornstarch feeds help in maintaining blood glucose for longer periods of time and decreasing episodes of hypoglycemia.

### PROGNOSIS

The prognosis is good in asymptomatic neonates with hypoglycemia of short duration, if the child has not incurred any CNS insult due to hypoglycemia. The regions of brain commonly affected by hypoglycemia are parieto-occipital region, hippocampus, caudate nucleus and putamen. The common changes seen on neuroimaging in children with hypoglycemia have been illustrated in **Figures 2A to D**. Prolonged, recurrent and severe symptomatic hypoglycemia is associated with long-term neurologic sequelae and intellectual disability, visual deficits, motor deficits manifesting as spasticity or ataxia, seizure disorder and even microcephaly. In a study done at a tertiary care center in south India, neonatal hypoglycemia was found to be the most common etiology of remote symptomatic infantile onset epilepsy. Babies with symptomatic hypoglycemia have a poorer prognosis than those with asymptomatic hypoglycemia. In babies with hypoglycemia related to inborn errors of metabolism, survival depends on the severity of the underlying defect.

**Figures 2A to D** Magnetic resonance imaging (MRI) brain showing changes due to hypoglycemic brain injury. (A) Abnormal signal intensity in parieto-occipital region; (B) Restricted diffusion on DWI in occipital region; (C) Loss of cerebral cortex and white matter; (D) Loss of differentiation between gray and white matter

### IN A NUTSHELL

1. Hypoglycemia is defined as blood glucose value less than 40 mg/dL in neonates, less than 50 mg/dL in older infants and children and less than 54 mg/dL in children with severe acute malnutrition.
2. Hyperinsulinism is the most common cause of persistent hypoglycemia in early infancy, for which the most common underlying etiology is persistent hyperinsulinemic hypoglycemia of infancy, while in older children, ketotic hypoglycemia is most common.
3. Collection of *critical sample* (blood glucose, insulin, cortisol, FFAs and urinary ketones) at the time of documented hypoglycemia helps in determining the underlying etiology.
4. The treatment comprises of management of hypoglycemic episodes, changes in the dietary pattern and use of drugs based on the underlying etiology.
5. Prolonged, recurrent and severe symptomatic hypoglycemia is associated with long-term neurologic sequelae. Hence, early detection and prompt management is essential.

## Chapter 3.18

# Porphyrias

Meenal Agarwal, Shubha R Phadke

Porphyrias are a rare group of disorders with pain in abdomen as the commonest manifestation in many of them. Abdominal pain mimics many surgical and medical conditions and diagnosis is often delayed or never made. As the acute attacks can be life-threatening, timely diagnosis is important. In addition to the clinical features similar to many common disorders, other symptomatology, mode of inheritance, intermittent presentations and decreased penetrance make this group of genetic metabolic disorders stand out.

Porphyrias are a group of eight inherited disorders of heme synthesis, each caused by deficiency of a specific enzyme in heme synthesis pathway. Porphyrins are organic compounds with four modified pyrrole rings. These pyrrole rings are interconnected through methane rings between their  $\alpha$ -carbon atoms. Porphyrins containing ferrous ion in the center are called heme and heme containing proteins are called hemoproteins. Examples of hemoproteins are oxygen carrying molecules (hemoglobin, myoglobin), cytochromes P450 which are involved in the metabolism of many drugs, cytochromes b and c are involved in oxidative phosphorylation, catalase, peroxidase and endothelial nitric oxide synthase. Hence, it is also called pigment of life. Block in the synthesis of heme causes accumulation of its precursors as well as deficiency of necessary heme-containing products.

### HEME SYNTHESIS PATHWAY

Synthesis of heme occurs in every human cell. However, 85% of it is synthesized in erythroid precursor cells in bone marrow to be incorporated in hemoglobin (**Fig. 1**). About 15–29% of heme is synthesized in the hepatocytes in the form of various cytochromes and other enzymes including catalase and peroxidase. The enzymes, their properties and a brief description of the type of porphyria associated are described in **Table 1**.

### Regulation of Heme Synthesis

Regulation of heme synthesis is controlled in liver mainly by negative feedback regulation by heme. In erythroid cells, control mechanisms are different as erythroid precursors have their own erythroid-specific enzymes for first four reactions [separate gene for 5-aminolevulinic acid synthase (ALAS), and separate transcripts for next three enzymes]. In erythroid precursors, ALAS2 is active during erythroid differentiation. Also heme synthesis is regulated by the level of iron transport. It is important to understand the physiological regulatory factors which control heme synthesis, because in most types of acute porphyria, the neurovisceral attacks are precipitated by recognizable events. In hepatocytes, the first enzyme of the pathway (ALAS1) is the rate-limiting enzyme. Fifty percent of reduced activity of enzymes in hepatocytes is sufficient to carry out the normal metabolic functions. The factors or events which use heme protein induce ALAS, and, hence, result in accumulation in heme precursors in various tissues and are thought to be precipitating factors for acute attacks. These factors include fasting or caloric restrictions, drugs inducing cytochrome P450 systems, alcohol, estrogen use in females, etc.

### CLASSIFICATION

There are several ways by which these disorders can be classified. One approach is to classify them according to the organ in which heme precursors mainly accumulate, i.e., hepatic or erythrocytic.

However, clinically useful classification is based on signs and symptoms. Most hepatic porphyrias [except porphyria cutanea tarda (PCT)] are associated with neurovisceral attacks, and most erythrocytic porphyrias have cutaneous manifestations as the predominant feature. PCT is a hepatic porphyria and mainly presents with cutaneous manifestations. Two other hepatic porphyrias, namely hereditary coproporphyria (HCP) and variegate porphyria (VP) may present with both neurovisceral and cutaneous symptoms.

### Acute Porphyrias

This group includes four hepatic porphyrias, i.e., acute intermittent porphyria (AIP), HCP, VP and rare aminolevulinic acid dehydratase deficient porphyria (ALADP). The symptomatic porphyrias are more common in females and pan-ethnic in distribution. The combined prevalence is around 5 in 100,000 with highest prevalence in Sweden (1 in 10,000). Each of these four acute hepatic porphyrias is caused by deficiency of distinct enzyme in heme biosynthesis pathway (**Table 1**), but clinical signs and symptoms are the same. Most people affected with the disorder develop symptoms in second or third decade and rarely after menopause. Only less than 10% of affected people suffer recurrent attacks (reduced penetrance). Because of reduced penetrance and nonspecific symptoms, high suspicion is to be kept in mind to make a diagnosis.

### PATHOGENESIS

In cutaneous porphyrias, porphyrins accumulate in bone marrow and skin. In skin, these accumulated porphyrins absorb light and convert to their ground state by transferring their energy to other molecules like membrane lipids, nucleic acid and other proteins and is the cause of photosensitivity. The causes of neurovisceral attacks are less clear. The pathogenic mechanisms which have been proposed include deficiency of enzyme/protein containing heme or accumulation of heme precursors. The accumulation of heme precursors are thought to be neurotoxic.

### CLINICAL FEATURES

#### Acute Porphyrias: Neurovisceral Attacks

Clinical symptoms are nonspecific, mimic other medical acute conditions and highly variable in the same individual or different members of the same family. None of symptoms is specific to acute porphyria but few suggested features which may point toward the diagnosis are—recurrent nonspecific neurovisceral symptoms not associated with inflammatory reaction, women of reproductive age group, presence of family history, dark-colored urine, proximal muscle weakness during attack, cyclical symptoms associated with luteal phase of menstrual cycle, antecedent history of fasting, intercurrent illness and exposure to drugs which are known to precipitate acute attacks. The neurovisceral attacks classically present in the form of recurrent abdominal pain with or without vomiting, muscle paralysis and psychiatric symptoms. Severity of symptoms may range from mild to severe requiring ventilatory support and, if untreated, may lead to death. Systemic signs of infection or inflammation, like tenderness and leukocytosis are absent. Biochemical investigations are essential to make a definite diagnosis. The summary of clinical symptoms is presented in **Table 2**.

#### Cutaneous Signs and Symptoms

Cutaneous signs may be divided into two categories: (i) blistering type, and (ii) nonblistering type. The porphyrias which present with cutaneous signs and symptoms include congenital erythropoietic porphyria (CEP), hepatoerythropoietic porphyria (HEP), VP,

**Figure 1** Steps in biosynthesis of heme. There are eight enzymes in this pathway. Four reactions are cytosolic (2nd, 3rd, 4th and 5th) and four are mitochondrial. Each enzyme is coded by an autosomal gene except first enzyme  $\delta$ -aminolevulinic acid synthase which has two isoforms coded by two different genes: (i) housekeeping gene ALAS1; and (ii) erythroid-specific ALAS2. Every enzyme deficiency is associated with separate class of porphyria which is illustrated in the figure. Second, third and fourth enzymes have different housekeeping and erythroid-specific transcripts, mainly formed by alternate promoters or splicing. Out of all the genes in hemesynthetic pathway, only ALAS2 is situated on X chromosome. Numbers written inside yellow circles represent sequential reactions and enzymes responsible for each step are as follows: 1. 5-aminolevulinic synthase, 2. 5-aminolevulinic dehydratase, 3. hydroxymethylbilane synthase, 4. uroporphyrinogen III synthase, 5. uroporphyrinogen decarboxylase, 6. coproporphyrinogen oxidase, 7. protoporphyrinogen oxidase, 8. ferrochelatase.

Source: Adapted from the book chapter "Inherited Porphyrias" in Emery and Rimoin's Principles and Practice of Medical Genetics, 5<sup>th</sup> ed. Volume 3, 2006.

erythropoietic protoporphyria (EPP), PCT and rare HCP. Blistering type of lesions include friability, edema and vesicle formation in sun-exposed parts, mainly dorsum of hands. Later on, they may present with hypertrichosis, abnormal pigmentation, skin scarring and mutilation of fingers. Nonblistering type of cutaneous photosensitivity is mainly characteristic of EPP, which mainly presents with burning pain as soon as skin is exposed to sun, sometimes described like prick of a hot needle. EPP is generally not associated with blister formation.

## LABORATORY INVESTIGATIONS

### Acute Porphyrias

Laboratory investigations should begin as soon as there is suspicion of porphyria. In case of acute porphyria, first screening investigation is measurement of urine porphobilinogen (PBG) level which should immediately be done in any patient with nonspecific neurovisceral symptoms with or without cutaneous symptoms. Increased urinary PBG level (20–200 mg/dL) can detect acute porphyria with high sensitivity and specificity. Urine PBG levels are much higher and last for longer time in cases of AIP in comparison to VP and HCP. The cases which can be missed are ALA dehydratase-deficient acute porphyria [normal PBG with high aminolevulinic acid (ALA) level in urine] and patients who have already received hemin therapy. Apart from this, blood electrolytes level, blood glucose, liver function test and kidney function tests should also be done. Urine, plasma and fecal samples should be preserved for second line of investigations before treatment is started.

Once the diagnosis is confirmed by raised PBG levels in urine, treatment should start immediately as treatment protocol is similar in all acute porphyrias. Later, second line investigations can be performed which differentiate between different types

of porphyrias. These second line investigations include plasma fluorescence spectrum, high performance liquid chromatography and mass spectrometry, quantitative measurement of 5-ALA and porphyrins levels in urine, relative concentration of different porphyrins in plasma and stool, enzyme assay in erythrocytes and mutation analysis. The differentiation of different acute porphyrias needs to be done on the basis of biochemical investigations including porphyrins in urine and stools, plasma fluorescence peak, enzyme activity and molecular testing. VP has a characteristic peak plasma fluorescence emission at 624–627 nm and HCP has high stool coproporphyrin III.

### Genetic Mutation Analysis in Acute Porphyrias

All acute porphyrias except ALADP are inherited in an autosomal dominant manner (Table 1). ALADP is inherited in an autosomal recessive manner. Most molecular defects are family-specific and identification of molecular defect is essential to provide prenatal diagnosis or presymptomatic diagnosis. However, most patients (80–90%) who carry the mutation are clinically asymptomatic, and hence, prenatal diagnosis is usually not offered.

### Laboratory Investigations in Cutaneous Porphyrias

In porphyrias presenting with predominantly cutaneous symptoms with acute neurovisceral attacks, the first step is to analyze urine porphyrin levels. If urinary PBG levels are increased and neurovisceral symptoms are present, then a diagnosis HCP or VP should be considered and further differentiation can be done on the basis of biochemical tests. VP can readily be identified on the basis of peak plasma fluorescence emission at 624–627 nm. If neurovisceral attacks are absent and cutaneous symptoms are in

**Table 1** Characteristics of enzymes of heme synthesis pathway

**Abbreviations:** PBG, porphobilinogen; HMB, hydroxymethylbilane; ALA, aminolevulinic acid; EPP, erythropoietic porphyria or protoporphyria or erythropoietic protoporphyria; CEP, congenital erythropoietic porphyria; PCT, porphyria cutanea tarda; HEP, hepatoerythropoietic porphyria; HCP, hereditary coproporphyria; VP, variegate porphyria.

**Table 2** Clinical signs and symptoms in acute porphyrias

Abdominal pain	Usually the most common presenting symptom. Diffuse, generalized, often cramp, associated with nausea/vomiting/diarrhea/distension of abdomen, lasts from hours to days. Inflammatory signs like fever, peritoneal irritation and leukocytosis are usually absent
Central nervous system	Present in 40–60% of cases, may be variable from minor behavioral changes to acute psychiatric symptoms like agitation, confusion, hallucinations and depression. Seizures can also occur as neurologic manifestation or due to hyponatremia. Sometimes blindness, pyramidal signs, cerebellar signs and altered consciousness may also occur
Peripheral neuropathy	Mostly motor in early stages present with limb weakness. Later on, it may be associated with pain or sensory loss in extremities. Recovery from limb paralysis is slow and often incomplete. Sometimes may progress to bulbar or respiratory muscle paralysis and can be life-threatening
Others	Cardiac arrhythmias and sudden death, chronic arterial hypertension, renal insufficiency, liver cirrhosis and hepatocellular carcinoma
Cutaneous signs	Chronic blistering lesion in sun-exposed areas

**BOX 1 Treatment of acute porphyrias***Acute Management*

1. Hospitalization
2. Identify the precipitating event for the attacks (calorie restriction, drugs, day of menstrual cycle)
3. Stop all medications which can precipitate an acute attack of porphyria (list of unsafe drugs is available on site—[www.drugs-porphyria.org](http://www.drugs-porphyria.org))
4. Adequate calorie intake (total parenteral nutrition may be required in some cases)
5. 10% or 25% dextrose solution intravenously, 3–4 g/day (initial treatment for mild attacks)
6. Infusion of hemin preparation (hemin, heme albumin or heme arginate) is the most effective therapy in acute attacks which is given in a dose of 3–4 mg/kg/day over 10–15 min once daily at least for 4 days and may be prolonged on the basis of clinical presentation
7. Correct electrolyte imbalance (especially hyponatremia and hypomagnesemia)
8. Pain: opiates, aspirin
9. Nausea, vomiting: promethazine, chlorpromazine, ondansetron
10. Seizures: correct electrolyte imbalance and use antiepileptic drugs like gabapentin or lamotrigine
11. Symptomatic hypertension and tachycardia:  $\beta$ -adrenergic blockers (propranolol, atenolol, labetalol)
12. Constipation: bulk laxatives, lactulose
13. Close monitoring for nutrition, neurological signs, electrolyte imbalance, pulmonary function test and bladder distension
14. Respiratory muscle weakness: ventilator support in intensive care unit
15. Kidney failure: management of hypertension, dialysis, consider kidney transplantation.

*Surveillance and Chronic Management*

1. Stop smoking and alcohol consumption
2. Carry medical alert cards for diagnosis, medical records, list of harmful or safe drugs and emergency treatment.
3. Limb weakness: physiotherapy
4. For cyclical attacks in females: gonadotropin releasing hormone (GnRh) analogues with add back estradiol after 6 months (low dose combined oral contraceptive pills may be tried but they sometimes can precipitate attacks), weekly hemin infusion can be considered
5. Avoid prolonged fasting with adequate carbohydrate intake
6. For chronic psychiatric symptoms: education, psychological support, neuroleptics and antidepressant if required
7. For iron overload in patients receiving frequent hemin transfusion: iron chelators
8. Periodic renal function assessment
9. Surveillance for liver cell carcinoma (frequent imaging after 50 years of age). Kidney and/or liver transplantation in last stages
10. Early severe attacks: consider liver transplantation
11. Genetic counseling and education of family members.

the form of blisters, then first investigation is plasma fluorescence spectrum. Once VP is excluded, second test is estimation of fecal porphyrins. In porphyria cutanea tarda, isocoproporphyrins and 7-carboxylporphyrins are secreted in large quantity. If cutaneous symptoms are nonblistering painful variety, then measurement of protoporphyrin IX in erythrocytes is a sensitive measure for EPP. Enzyme assay and mutation analysis are final investigations in differentiating cutaneous porphyria.

**TREATMENT****Acute Porphyria**

Management of acute porphyria should begin as soon as screening test (urine PBG levels) is found to be positive. Management can be discussed under two separate subheadings: (i) acute management, and (ii) chronic management. Steps are summarized in **Box 1**.

**Treatment for Cutaneous Porphyria**

For cutaneous porphyria, there are some general management rules including protection of sun exposure and trauma, application of sunscreen lotion and treatment of secondary infection of skin lesions. For PCT, frequent phlebotomy and chloroquine or hydroxychloroquine is the mainstay of therapy. However, in cases of CEP, treatment of hemolytic anemia, hydroxyurea and  $\pm$  splenectomy have important role in management, and bone marrow transplantation is considered to be curative. In VP and HCP, avoidance of harmful drugs and acute management is important as described under the heading of acute porphyria above. In cases of EPP, use of  $\beta$ -carotene is the treatment of choice.

**IN A NUTSHELL**

1. Porphyrias are a group of eight inherited disorders of heme synthesis and classified as acute (hepatic) or cutaneous.
2. Pain in abdomen is the most common visceral symptom of porphyrias. Seizures and cutaneous manifestations are other presentations depending on the subtype.
3. Acute porphyrias include four hepatic porphyrias, i.e., acute AIP, HCP, VP and rare ALADP.
4. The porphyrias which present with cutaneous signs and symptoms include CEP, HEP, VP, EPP, PCT and rare HCP.
5. PCT is a hepatic porphyria and mainly presents with cutaneous manifestations. VP and HCP may present with both neurovisceral and cutaneous symptoms.
6. Increased urinary PBG level (20–200 mg/dL) can detect acute porphyria with high sensitivity and specificity.
7. Management should start as soon as the diagnosis is made.

## Chapter 3.19

# Newborn Screening

Seema Kapoor, Madhulika Kabra

Newborn screening (NBS) refers to screening of the newborn shortly after birth for potentially fatal disorders that are treatable but inapparent. Since there are no prototypic symptoms of inborn errors of metabolism (IEM), clinical diagnosis at birth is difficult. NBS is a coordinated comprehensive system with multiple components including education, screening (specimen collection, transportation and testing), follow-up of abnormal and unsatisfactory test results, confirmatory testing and diagnosis, treatment and periodic outcome evaluation, quality assurance and program evaluation, validity of testing systems, efficiency of follow-up and intervention, and assessments of long-term benefits to individuals, families and society.

## TEST AND DISEASE CHARACTERISTICS

### Test Characteristics

The test should be able to provide a value to decide whether the screening test is positive. This value is above a designated cut-off—placed generally beyond 99.9th percentile or below 0.11th percentile—depending on whether it is a high or a low marker. The cut-off is arbitrary and as in all physiologic parameters has a wide dispersion across the central value. Though it is set to increase the sensitivity, i.e., not to miss any case, this may also lead to a few false positives. Thus, for each screened positive result, a second analytical test is required for confirmation. The technology for the confirmatory test should be different from that used for the screening test. Each infant called back for retesting is labeled as *recall*. If there is a suspicion of a technical error, the test is repeated on the same filter paper sample punched from a different site (*repunch*) before recall. A recall may be associated with significantly parental anxiety and should be asked only if absolutely essential.

### Disease Characteristics

The disorders commonly screened are endocrine disorders like congenital hypothyroidism (CH) and IEM but also include nongenetic targets like hearing testing. These screening programs are often run by state or national governing bodies in developed countries with the goal of screening all infants born in their jurisdiction. Other disorders where this has been used are congenital infection like toxoplasmosis and inherited immune deficiency disorder like severe combined immunodeficiency. Disorders to be included in the screening program differ from country to country. For most developed countries, initial targets for screening were phenylketonuria and congenital hypothyroidism, but now include congenital adrenal hyperplasia (CAH), cystic fibrosis, galactosemia, glucose-6-phosphate dehydrogenase (G6PD) deficiency, biotinidase deficiency, hemoglobinopathies (sickle cell disease) and nongenetic targets such as hearing and intrauterine infections. The recent introduction of pulse oximetry to this program has an added value of screening for critical congenital heart disease.

### Criteria for Disease Selection

It may not be economically and ethically viable to screen for a complete range of disorders for which diagnostic modalities are available. Wilson and Jungner have outlined specific criteria (**Box 1**) that can serve as a template to decide what disorders to include in the screening at a national platform.

### BOX 1 Wilson and Jungner criteria for disease screening

- The condition sought should be an important health problem
- There should be an accepted treatment for patients with recognized disease
- Facilities for diagnosis and treatment should be available
- There should be a recognizable latent or early symptomatic stage
- There should be a suitable test or examination
- The test should be acceptable to the population
- The natural history of the condition, including development from latent to declared disease, should be adequately understood
- There should be an agreed policy on whom to treat as patients
- The cost of case-finding (including diagnosis and treatment of patients diagnosed) should be economically balanced in relation to possible expenditure on medical care as a whole
- Case-finding should be a continuing process and not a *once and for all* project.

## CORE AND EXPANDED PANEL

*Core panel* indicates the basic minimum set of disorders for which screening should be advocated at a national level. Since all countries chose the set of disorders to be initiated in their domain based on epidemiologic prevalence and resources, the panel across the world is not uniform. This distinction not only outlines the group to be tested but also the differences in technology for the set of disorders included in each category. The term *expanded newborn screening* emerged after the introduction of tandem mass spectrometry (MS/MS) into the newborn screening program, which can handle simultaneous screening of multiple analytes from the same drop of blood.

### Diseases Included in the Core Panel of All Countries

#### Congenital Hypothyroidism

This disorder serves as a template to introduce NBS in any country. It is the commonest cause of preventable mental retardation, but therapy is easily and economically available to even the least affording. Both thyroid stimulating hormone (TSH) and tetraiodothyronine (T4) can be used for an ideal screening test as the former identifies the primary hypothyroidism and T4 identifies both primary and secondary hypothyroidism. The ideal time to collect samples is between 72 hours and 7 days of life. The treatment if initiated within the first 2 weeks, it is associated with a normal outcome in all domains of development. Since it is a screening test, it is always important to confirm this by doing a venous sample for estimating free triiodothyronine (T3), free T4 and TSH. It is important to mention here that central hypothyroidism, which is due to defects in the hypothalamo-pituitary axis, is reflected in the low levels of TSH and will not be picked up while using TSH as a primary approach.

#### Congenital Adrenal Hyperplasia

This group of disorders involving deficiency of 21 $\alpha$ -hydroxylase causes either genital ambiguity in a female child or a salt-wasting type of presentation, often mistaken as sepsis in the neonatal period in a male infant. The variety presenting later in life is called the nonclassical CAH and can be missed in newborn screening. This is also included in the core panel of many countries. The analyte tested for it is 17-hydroxyprogesterone (17-OHP). Since this analyte is prone to elevations due to stress and parturition, it needs to be adjusted for both gestational age and weight. Significant elevations of 17-OHP early in life may not indicate CAH and the magnitude of elevations does not correspond with true positivity. A second

tier testing using residual blood spots obtained on filter paper for steroid profiling for confirmation delineates levels of cortisol, 17-OHP and androstenedione. This helps in deciding a true CAH child versus a sick neonate under stress with raised cortisol levels.

### **Glucose-6-Phosphate Dehydrogenase Deficiency (G6PD)**

This is included in the core panel of screening programs of many South-East Asian countries and should also be targeted for screening in India. Data from Chandigarh suggests an incidence of 1 in 112 and from eastern India an incidence of 1 in 15. This disorder has been genotypically well mapped from different parts of the country with G6PD Mediterranean (563 C-T) being seen commonly in North India, G6PD Kerala-Kalyan (949 G-A) in Maharashtra, Kerala, Andhra Pradesh, Tamil Nadu and Punjab and G6PD Odisha (131 C-G) in tribals of Central, Eastern and Southern India.

### **Deafness**

Screening for deafness is important because provision of hearing aid early in the prelingual phase can minimize the negative impact of sensorineural hearing loss on speech and language acquisition. Techniques currently used in newborn hearing screening can discriminate peripheral (cochlear) from central (brain stem) auditory function. Two-phase screening using otoacoustic emissions (OAEs) and auditory brainstem response (ABR) allows detection of various failure patterns.

### **Expanded Panel**

The introduction of MS/MS technology for analysis has enabled us to screen for disorders of metabolism of fatty acid, amino acids and organic acids. Targeted or high risk screening may identify a higher proportion of affected neonates. MS/MS allows other disorders to be added for screening without a need for additional samples or analysis time. The initial cost of MS/MS might be quite high, but the analytical cost per sample for screening approximately 45 disorders is US \$10–20, and the addition of another disorder to the panel may be less than \$1. Most developed countries have expanded NBS programs that screen from approximately 20 to over 40 inherited metabolic diseases by MS/MS. Availability of confirmatory testing and treatment appear to be the major rate limiting factor in implementing expanded screening in India.

### **Other Disorders**

Others disorders included in many country programs are screening for cystic fibrosis, toxoplasmosis, hemoglobinopathies, biotinidase deficiency, galactosemia and, more recently, for lysosomal storage disorders. For inclusion of every new disorder in the country program, a brainstorming is required to revisit its need in the light of available evidence.

## **LOGISTIC ISSUES**

### **Optimal Timing and Method of Sampling**

The American Academy of Pediatrics has advocated the ideal time of sampling after 72 hours and within 7 days of life. However, this policy would be very difficult in Indian patients to adopt due to high birth rate, limited space in most hospitals and difficulty in keeping the mothers in the hospital for longer than 24 hours. California screening program recently evaluated the performance of screening at 12 hours and found it satisfactory. We suggest that the analytes can ideally be measured at or after 24 hours of life when enteral feeding has been established, renal function is improving and hepatic metabolism is in the process of becoming mature. At birth, the plasma levels of amino acids, organic acids and acylcarnitines are not easily distinguishable between normal infants and those born with an inborn error of metabolism. Collection of sample prior to 24 hours could compromise sensitivity of certain screening

tests. Thus, it may be ideal for our set-up to take the sample after first 24 hours of life. If a sample is collected from an infant less than 24 hours old, a repeat specimen should be taken after 24 hours.

Low birth weight or premature babies, and those in a special care nursery (SCN) or neonatal intensive care unit (NICU) should have repeated screening at 2, 6 and 10 weeks of age or until the infant reaches 1,500 g. This has been advocated primarily to evaluate neonates with a delayed rise in TSH. Newborns that require red blood cell transfusion should have a blood specimen for NBS collected prior to the transfusion. This is important for detecting galactosemia by RBC enzyme analysis and hemoglobinopathies by hemoglobin electrophoresis prior to transfusion if this is the panel being screened. A follow-up newborn screen should then be obtained 2 months after the transfusion.

### **Tool for Collection**

Newborn screening tests are most commonly done from whole blood samples collected on specially designed filter paper. This filter paper allows blood to elute out on washing without letting shreds of filter paper coelute and block the analytical machinery. The filter paper is often attached to a form containing required information about the infant and parents. This includes date and time of birth, date and time of sample collection, the infant's weight and gestational age. The form also has information about whether the baby has had a blood transfusion and any additional nutrition the baby may have received (total parenteral nutrition). A repeat specimen (if required) should be written boldly on the top.

### **Blood Sample Collection**

Dried blood spots should be collected by heel-prick on the blood sample collection cards. The heel is punctured with a firm deliberate stab with lancet on the medial or lateral aspect. The depth of the puncture should not exceed 2.4 mm which is ensured by using a lancet which will not puncture beyond the certain depth. If a second puncture is necessary, this is made a few millimeters away from the first or in other foot. At least, three (preferably five) blood spots should be collected from each neonate. Venous sample should only be collected if sampling is being done for some other test so that two pricks can be avoided. A typical sample filter paper is depicted in **Figure 1**. The divisions in the filter paper are for tests going for the fluoroimmunoassay or enzyme-linked immunosorbent assays (ELISA) system and two circles for expanded screening; this may differ from country to country. The circle marked on the card is touched gently to the hanging drop so that blood soaks through the other side. It is very important not to put drops on both sides of a circle. The card should not be pressed onto the skin. The blood spot should not be touched with a finger.

### **Drying and Transport**

The sample collected should be dried at room temperature in a horizontal position. Specially designed stands can be used for drying. Any other drying agent like a lamp, dryer or sunlight should not be used to dry the filter paper as it may degrade the analyte or the enzyme contained in the filter paper. Moisture may harm the specimen by inducing bacterial growth or altering the elution time of the specimen. In ambient temperatures, it would take 4 hours on an average before it can be sent to laboratory for testing. The sample collected can ideally be sealed in a zipped bag which should contain a desiccant, put in a paper envelope and sent for testing. Dried blood spot specimens protected in this manner can be stored at –20°C for many weeks or years.

### **Common Sample Collection Problems**

Common sampling problems include insufficient blood (not filling all circles), not enough sample to perform tests or repeat tests. Milking or squeezing the puncture site can cause hemolysis and mixing of tissue fluids with blood. Layering or applying successive

drops of blood (double collection) in the same printed circle causes caking and/or nonuniform concentrations of blood. If the blood flow diminishes, such that circles are not completely filled, then repeat the sampling technique in a new circle. Contamination of sample during collection, drying or mailing with urine samples will render the results unreliable. Humidity and moisture adversely affect the quality of sample and analyte recovery.

### COMPONENTS OF NEWBORN SCREENING: FOLLOW-UP

As the initial test in the NBS process is a screening test, there is a possibility of false positive (abnormal test, normal infant) and false negative (normal test, affected infant) results. NBS test results are mostly negative, which means that the infant does not have any IEM for which laboratory tests are performed. Screen positive results are repeated from the original dried blood spots (DBS) and when the repeated test reveals a positive result. This is called a repunch to exclude technical errors in the report. Screen positive results should be confirmed by other tests including plasma amino acid, acylcarnitine and urine organic acid profiles to avoid false abnormalities which may not be due to a metabolic disease. If the results from the confirmatory tests are positive, the sample is sent for molecular confirmation of the same.

False-positive results lead to additional testing and parental anxiety, and long-term consequences such as the vulnerable child syndrome may occur. False-negative results may lead to a delay in diagnosis, because the healthcare professional may be falsely reassured by a normal NBS result. Finally, it must be emphasized that *normal* results of newborn screenings do not rule out the presence of these disorders, because some variants of these conditions may have onset later in life, and false-negative results may occur. The clinical judgment of the pediatrician remains the most important tool in the diagnosis of all of these conditions. Proper follow-up of a *not-normal* screening result is crucial, if mortality, morbidity and disabilities are to be avoided. The primary function of the follow-up program is to locate infants with abnormal screening results and facilitate timely diagnostic testing and management. The time-frame for follow-up will vary by disorder and by the degree of abnormality of the screening result. The pediatrician is usually the provider of first contact for screen positive infants.

The determination of an abnormal newborn screen result sets into motion a cascade of notification, plan of action and documentation. In case the analyte test result is considered by the screening program to be borderline elevated, the recommendation

will be to send a repeat newborn screen to the program. A newborn discharged to home can have the repeat screen drawn in the pediatrician's clinic, healthcare facility or in the reference laboratory. Infants still hospitalized are readily retested at the hospital. This procedure is called *recall*. It is needless to stress that confirmatory biochemical and molecular tests are to be done in all screen positive cases. These tests should be performed at a medical center or in consultation with a genetic specialist or pediatric endocrinologist.

### Disease Management

Infants affected with disorders detected by NBS usually require lifelong management. For every child, care should be accessible, family-centered, continuous, comprehensive, coordinated, compassionate and culturally competent. The pediatrician plays a central role but may need consultation with experts who understand the etiology, pathophysiology, clinical heterogeneity and psychosocial issues associated with the disorder. Genetic counseling, including discussion of carrier testing of family members and prenatal diagnosis of future pregnancies, may be indicated.

### Second-tier Testing

The false positive results and relatively poor positive predictive value for some MS/MS tests have led to the development of a number of second-tier tests. Each of the secondtier tests requires a separate testing protocol and rapid turnaround of results is required. The second tier tests available and incorporated into the NBS programs are for tyrosinemia I, propionic acidemia, maple syrup urine disease (MSUD), CAH, hyperammonemia-hyperornithinemia hyperhomocitrullinemia (HHH), methylmalonic acidemia and galactosemia. The second-tier testing is usually performed on the same residual blood spots to minimize recall and undue parental anxiety.

### NEWER DEVELOPMENTS

Newer developments in the field of NBS have widened the debate on the ethics of newborn screening. One important introduction in this field is the inclusion of testing for disorders like treatable lysosomal storage disorders, which include Gaucher disease, Pompe disease, Fabry disease and mucopolysaccharidosis I to name a few. This may be vital in presymptomatic institution of enzyme replacement therapy, where it is likely to be of utmost importance. However, in resource constraint settings like ours, this may see the application at a date when resources could be allocated to them.

### IN A NUTSHELL

1. Newborn screening is probably one of the important public health programs akin to the immunization program in both predictive and presymptomatic.
2. *Core panel* indicates the basic minimum set of disorders for which screening should be advocated at a national level. These include screening for congenital hypothyroidism, congenital adrenal hypoplasia, deafness and G6PD deficiency.
3. *Expanded panel includes screening for 20–40 disorders.* The introduction of MS/MS technology for analysis has enabled us to screen for disorders of metabolism of fatty acid, amino acids and organic acids.
4. The recent program launched by the Government called RBSK program (Rashtriya Bal Swasthya Karyakram) has included screening for CH as one of the deficiencies at birth to be targeted. Probably, this initiative will initiate and integrate the process to which diseases will be added subsequently.

## Section 4

# IMMUNITY, IMMUNE DISORDERS AND ALLERGY

**Section Editors** Surjit Singh, Amit Rawat

## Chapter 4.1

### Basics of Immunology

Amit Rawat, Biman Saikia

*Immunity* originates from the Latin root *immunis*, meaning *exempt* and is used to refer to a state of protection from disease, more particularly infectious disease. It was observed by our astute ancestors that individuals who recovered from particular infectious disease were subsequently protected from that disease. Thucydides, a Greek historian was perhaps the first to provide a written account of *immunity* in 430 BC. In his description of the plague of Athens, he intuitively highlights that *only those who have recovered from the plague can nurse the sick, as they could not contract the disease a second time*. There is also a reference to the concept of immunity in *Ayurveda* where it is referred to as *Vyadhiksamatva* which literally means resistance to disease.

The immune system is an intricately orchestrated and dynamic network of cells and cell-associated as well as soluble molecules which protect us from infectious agents and the development of tumors. Certain components of the immune system are phylogenetically ancient and are conserved across species in the animal kingdom. In fact, some elements of this ancient system are also found in plants. However, the immune system is also a mediator for a host of diseases including autoimmune diseases and hypersensitivity reactions. On the other hand, deficiencies of individual components of the immune system are experiments of nature which result in a group of disorders known as primary immunodeficiency diseases. The immune system also poses a formidable barrier to organ transplantation and to gene therapy using viral vectors.

The two major components of the immune system in the jawed vertebrates are the innate immune system and adaptive immune system. The innate immune system is the evolutionarily primitive and more conserved element of the immune system. Innate immunity is referred to as *Sahaja Bala* and acquired immunity as *Yuktikrita Bala* in the Ayurvedic System of Medicine.

### CELLS AND ORGANS OF THE IMMUNE SYSTEM

All mature immune cells in humans are derived from a single cell type known as the hematopoietic stem cell. Stem cells possess the property of *self renewal* and the ability to differentiate into various cell types depending on the differentiation factors acting on these cells.

**Primary lymphoid organs** The development and maturation of immune cells takes place in two major organs of the body known as the primary lymphoid organs. These include:

- **Bone Marrow** The stem cells reside in the marrow and give rise to the various progenitors; and
- **Thymus** T-cell progenitors egress the bone marrow and complete their maturation in thymus.

**Secondary lymphoid organs** The secondary lymphoid organs include the lymph nodes, spleen and specialized aggregates of lymphoid tissue in the gut and other mucosal surfaces in which the naïve immune cells encounter their cognate antigens and get activated to form effector and memory cells.

**Tertiary lymphoid organs** These are organs which are sites of infection. These include liver, lung and skin. Lymphocytes activated in the secondary lymphoid organs can return to the tertiary lymphoid organs as immune effector cells or can reside in these organs as resident memory cells.

**Cells of the immune system** Cells of the innate immune system include neutrophils, monocytes or macrophages, dendritic cells and the innate lymphoid cell whereas the predominant cells of the adaptive immune system are the T- and B-lymphocytes and their various subsets.

### INNATE IMMUNE SYSTEM

The innate immune system is essentially the first responder to microbial invasion and to damaged, injured or dead self-cells. As the first line of defense against microbes, the innate immune system institutes mechanisms to prevent, control or eliminate the invading pathogens. It also stimulates the adaptive immune system by providing the appropriate *danger signals*. The innate immune system further senses damaged and injured self-cells playing a key role in wound healing and tissue repair.

#### Components of the Innate Immune System

- **Anatomical Barriers**
  - **Physical barriers:** Epithelia of skin, mucosa of respiratory, gastrointestinal and urogenital tracts.
  - **Chemical barriers:**
    - Acidic pH (stomach)
    - Antimicrobial proteins and peptides (defensins, cathelicidins, lysozyme, lactoferrin, collectins (surfactant proteins).
- **Cellular Components of the Innate Immune System**
  - Phagocytic and antigen-presenting cells (APCs)
    - Neutrophils
    - Macrophages
    - Dendritic cells
  - Innate lymphoid cells (subset of lymphocytes with limited diversity and a restricted repertoire of antigen-recognition receptors)
    - Natural killer (NK) cells
    - Invariant NKT cells
    - B1B and marginal zone B-cells
- **Soluble Components of the Innate Immune System**
  - Plasma proteins
    - Complement components and their fragments (C1q)
    - **Collectins:** Mannose-binding lectin, surfactant proteins (SP-A, SP-D)
    - **Ficolins:** L-ficolins and H-ficolins
    - **Pentraxins:** C-reactive protein

- Cytokines and chemokines (hormones of the immune system).

Cytokines are soluble protein molecules secreted by a wide variety of immune as well as nonimmune cells that regulate the immune response by activating or inhibiting target cells on which they act. The transcription of several key cytokines is induced by the activation of pattern recognition receptors (PRRs) present on the innate immune cells.

Chemokines are a subtype of cytokines which serve as chemoattractant molecules. They mobilize immune cells by affecting the cytoskeletal proteins in the immune cells and the expression of surface-associated cell adhesion molecules.

The predominant cytokines involved in the innate immune response are as follows:

- *Proinflammatory cytokines*: Interleukin-1 (IL-1), tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ), IL-6
- *Cytokines mediating antiviral action*: Type I interferons (IFN): IFN- $\alpha$  and  $\beta$
- *Chemokines*: Macrophage chemotactic protein-1 and IL-8.

### Key Features of the Innate Immune System

- Phylogenetically ancient system (evolved before the adaptive immune system).
- Does not require prior contact with the pathogen to mount an effective response.
- Activated and responds within minutes to hours after the initial encounter with a pathogen.
- Has limited diversity, constrained by a fixed repertoire of conserved receptors which respond to broad classes of pathogens.
- Has limited memory when compared to the adaptive immune system.

The features of the innate immune system have been compared with the adaptive immune system in **Table 1**.

### Recognition of Pathogens by Innate Immune System

Immune recognition by innate mechanisms is accomplished by a special class of receptors which recognize structures or moieties which are not present in host cells. These receptors are known as PRRs. Innate immune cells display an array of these PRRs on their plasma membrane as well as endosomes and lysosomes. PRRs are strategically located to recognize both extracellular and intracellular pathogens. Structures recognized by these PRRs are known as pathogen-associated molecular patterns (PAMPs).

However, these PRRs also recognize certain endogenous components released from damaged and injured self-cells. These

endogenous components recognized by the PRRs are known as damage-associated molecular patterns (DAMPs).

### Types of Pattern Recognition Receptors

There are four major types of PRRs in humans. These are located on the cell surface or inside the cell depending on the pathogens they are designed to recognize. These PRRs are:

- Toll-like receptors (TLRs)
- C-type lectin receptors
- Nucleotide oligomerization domain (NOD) or leucine rich repeat containing receptors [NOD-like receptors (NLRs)]
- Retinoic acid-inducible gene-I-like receptors.

### Toll-like Receptors (TLRs)

They constitute the best characterized and studied family of PRRs and were the earliest PRRs to be discovered. Several exciting and path-breaking discoveries have been made in the past 2 decades with regard to these receptors. Single gene mutation in TLR3 resulting in increased susceptibility to herpes simplex encephalitis has been described recently.

The association of single nucleotide polymorphisms in several of the TLRs has also been described for various infectious and noninfectious diseases.

**Human TLRs and their ligands** A total of 10 TLRs, TLRs 1–10, have thus far been identified in humans. TLRs 1–10 are conserved between mice and humans, whereas mice have additional TLRs 11–13. TLRs bind specifically to their respective PAMPs. Human TLRs with their known ligands and their location are summarized in **Table 2**.

**Signaling through TLRs** The binding of TLRs to their cognate pattern associated molecular pattern ligands results in activation of downstream signaling pathways. The signaling pathway activated is determined by the TLR and the adaptor protein that binds to the cytoplasmic domain of that TLR. This cytoplasmic domain of the TLR is known as toll or IL-1 receptor domain. Most of the TLRs bind to the adaptor protein myeloid differentiation factor 88 (MyD88). The MyD88 pathway activates the nuclear factor kappa B (NF- $\kappa$ B). The NF- $\kappa$ B is a key transcription factor which activates several genes which are important in an innate immune response. These include genes encoding for antimicrobial peptides such as defensins, proinflammatory cytokines, e.g., TNF- $\alpha$ , IL-1 $\beta$  and IL-6 and chemokines.

The other important adaptor for TLRs is TIR-domain-containing adaptor-inducing interferon- $\beta$  (TRIF). TLR3 binds exclusively to the TRIF whereas TLR4 is more promiscuous binding both MyD88 and TRIF depending on whether it is present on cell surface or the endosome respectively. The engagement of the TRIF by TLRs results in the activation of interferon regulatory factors (IRFs). These IRFs are instrumental in transcriptional upregulation of genes encoding for type I IFN. Type I IFN such as IFN- $\alpha$  and  $\beta$  have potent antiviral properties.

Mutations in adaptor proteins such as MyD88 and IL-1-receptor-associated kinase 4 involved in the signaling pathway of TLRs have also been identified.

**Nucleotide oligomerization domain (NOD) receptors/Nucleotide oligomerization domain leucine-rich repeat containing receptors (NLRs)**

The NLRs or NOD-like receptors constitute a large family of cytosolic PRRs which is activated by several intracellular PAMPs as well as DAMPs and other harmful endogenous substances. There are 23 genes in the human genome encoding for various NLRs. The NLRs are subdivided into 3 major categories based on their N-terminal domain.

**Table 1** Comparison of the key features in innate versus adaptive immunity

Key feature	Innate immunity	Adaptive immunity
Rapidity of response	Immediate within hours	Delayed with a lag phase between exposure and response
Antigenic specificity	Broad, limited repertoire and fixed	Highly specific and evolves with time during the course of an immune response
Immunologic memory	None	Exquisite memory, rapid and heightened response to previously encountered antigens
Self/nonself recognition	Present	Present, occasional lapses resulting in autoimmunity

**Table 2** Human toll-like receptors with their ligands

Toll-like receptor (TLR)	Ligands	Microbe	Location	Gene defects/polymorphisms
TLR 1	Triacyl lipopeptides	Gram-negative bacteria Mycobacteria	Plasma membrane	Susceptibility to tuberculosis
TLR 2	Peptidoglycan Zymosan Lipoproteins Phosphatidylserine glycosylphosphatidylinositol-linked proteins	Gram-positive bacteria Yeasts and fungi Mycobacteria Schistosomes Trypanosome	Plasma membrane	Susceptibility to tuberculosis, leprosy, staphylococcal infection
TLR 3	Double-stranded RNA (dsRNA)	Viruses	Endosome Lysosome	Herpes simplex encephalitis
TLR 4	Lipopolysaccharide Mannans F-protein	Gram-negative bacteria Fungi Respiratory syncytial virus	Plasma membrane Endosome Lysosome	Excessive TLR4 signaling in gram-negative septicemia
TLR 5	Flagellin	Bacteria	Plasma membrane	Associated with including risk of Legionnaires' disease
TLR 6	Zymosan Diacyl lipopeptides	Yeasts and fungi Mycobacteria	Plasma membrane	Associated with including risk of Legionnaires' disease
TLR 7	Single-stranded RNA (ssRNA)	Viruses	Endosome Lysosome	Association with hepatitis C infection
TLR 8	Single-stranded RNA (ssRNA)	Viruses	Endosome Lysosome	Association with pulmonary TB and hepatitis C infection
TLR 9	CpG dinucleotide Hemozoin	Bacterial DNA Malarial pigment	Endosome Lysosome	Polymorphisms associated with systemic lupus erythematosus
TLR 10	Unknown	Influenza virus	Endosome Lysosome	Not known

1. *NLRs*: Caspase recruitment domain (CARD)
2. *NLRBs*: Baculovirus inhibitory repeat domain
3. *NLRPs*: Pyrin domains.

Nucleotide oligomerization domain 1 and NOD2 are the best characterized members of the NLR family. They are activated by components of the cell wall peptidoglycans of intracellular and extracellular bacteria. These are produced during the synthesis or degradation of the bacterial cell walls. Both NOD1 and NOD2 form signaling complexes that activate NF- $\kappa$ B leading to upregulation of transcription of several proinflammatory cytokines.

Some NLRs do not trigger signaling cascades leading to upregulation of expression of genes which affect the innate immune response. These NLRs form complexes with other proteins that stimulate proteases that cleave inactive forms of IL-1 and IL-18 into their mature and active form. These complexes of NLRs with other proteins and proteases are collectively referred to as *inflammasomes*.

**Inflammasome** Three NLRs, namely NLRP1, NLRP4 and NLRP3 have been found to form inflammasomes. Of these the NLRP3 is the best studied and characterized. The NLRP3 is expressed on several cell types including, monocytes, macrophages, dendritic cells, neutrophils, some lymphocyte subsets and epithelial cells. The NLRP3 inflammasome comprises of multiple copies of NLRP3, the adaptor protein ASC (apoptosis-associated speck-like protein containing a CARD) and caspase 1. These components are assembled in the form of a pentameric or hexameric structure.

### Activators of NLRP3

- *Nonmicrobial or sterile activators:*
  - *Self-derived molecules and substances:* Glucose; cholesterol and urate crystals; amyloid  $\beta$ -protein; adenosine triphosphate
  - *Non-self-environmental substances:* Asbestos; silica; alloys; alum

- *Pathogen-associated activators:*
  - *Bacterial activators:* Flagellin, peptidoglycans, pore-forming toxins
  - *Virus:* Viral RNA, influenza M2 protein
  - *Fungus:* Mannan; zymosan;  $\beta$ -glucans
  - *Protozoa:* Hemozoin (malaria).

Mutations in genes encoding for various components of the inflammasome are responsible for a group of rare heritable genetic disorders known as autoinflammatory syndromes.

### ADAPTIVE IMMUNITY

Adaptive immune response can be divided broadly into two arms which function separately but not necessarily independent of each other: *humoral immunity* and *cell-mediated immunity* (CMI). This classification is based on the components of the immune system that mediate these responses viz. humoral (humor: fluid) immunity is mediated by soluble components in the plasma composed mainly of antibodies, produced by B-lymphocytes and the complement proteins whereas cell-mediated responses are mediated mainly by T-lymphocytes. These two distinct arms of the adaptive response basically execute two distinct functions. The humoral response is designed to neutralize and eliminate extracellular microbes and toxins to which antibodies are accessible. The humoral response however is ineffective against intracellular microbes and microbes which survive and replicate inside the infected cells are taken care of by the cell-mediated response, wherein the infected cell is targeted and killed by a cytotoxic T-cell response to eliminate the organism and its reservoir. Cardinal features of the adaptive immune response are:

- *Specificity for distinct antigens* This specificity exists because individual lymphocytes express membrane receptors that are capable of distinguishing subtle differences in the antigens.

- Diversity, accounted to by an extremely large number of antigenic specificities of the lymphocytes in an individual called the lymphocyte repertoire, a result of extreme degree of diversity inserted into the antigen binding regions of the T-cell and B-cell receptors (BCRs) by combinatorial gene rearrangements.
- Memory, which accounts for the enhanced response of the immune system to re-exposure to the same antigen that generated and expanded the specific clone.

### Phases of the Adaptive Immune Response

The step-wise development of the adaptive response is brought about by distinct cell populations: the nonlymphoid APCs (viz. mononuclear phagocytes, dendritic cells, epithelial cells), lymphocytes (B-cells and T-cells, the latter comprising of CD4+ (cluster of differentiation 4+) helper T-cells and CD8+ cytotoxic T-cells) and effector cells (activated T-cells and phagocytes). The adaptive response can accordingly be divided into three phases: recognition of antigen, activation of lymphocytes and the effector phase.

The initiation of the response is brought about by the APCs, which are nonspecific responses as part of the innate response, which display the antigens to the antigen-specific lymphocytes culminating in the effector response and elimination of the invading pathogen. The APCs, hence bridge the innate and adaptive responses.

### Antigen Recognition and Presentation

The fundamental interaction between the APC and the lymphocyte happens through surface receptors which in the B-cell necessarily is a membrane bound antibody molecule (BCR) and in T-cells is the T-cell receptor (TCR). This interaction is antigen specific, i.e., the BCR and/or the TCR recognize specific epitopes of the antigen and hence only specific clones from the entire repertoire of T-cells and B-cells would be engaged in the antigen recognition which will lead to a specific clonal expansion. Whereas, the BCR recognize and bind to antigenic determinants of a macromolecule directly recognizing epitopes on a tertiary folded structure, TCR can recognize only the antigenic peptides processed by the APC machinery and presented in the context of self-major histocompatibility complex (MHC) molecules. Hence, antigen recognition by T-cells is self-MHC restricted.

The MHC molecules, also called the human leukocyte antigens (HLAs) are of two classes: HLA Class I, (expressed on the surface of all nucleated cells) and HLA Class II (expressed on APCs and B-cells). An antigen presented in context to HLA Class I molecule will engage a CD8+ cytotoxic T-cell whereas its presentation through HLA Class II molecule will engage a CD4+ helper T-cell. This segregation of antigen presentation represents two basic pathways: extracellular antigens taken up by the APC via phagocytosis or endocytosis are processed in the phagolysosomes and subjected to lysosomal proteases generating antigenic peptides which are loaded onto Class II MHC molecules in the endosomes and presented to CD4+ T-cells. On the other hand, intracellular antigens, which could be ubiquitinated misfolded proteins or proteins synthesized by viruses or other intracellular pathogens are processed through the proteasome machinery to produce peptides which are then loaded onto Class I MHC molecules in the endoplasmic reticulum and presented to CD8+ T-cells. These two pathways are however not strictly segregated in the sense that cytosolic proteins can be processed through the endosomal pathway and presented through Class II MHC and vice versa (antigen cross-presentation).

### Lymphocyte Activation

The engagement of the TCR or the BCR with its cognate antigen constitutes the first signal towards activation of the responder

lymphocyte. This signal, however, in itself is not enough to drive the T-cell machinery towards activation. A second *co-stimulatory signal* is provided simultaneously through the co-stimulatory molecules.

### T-cell Activation

T-cell activation, through the self-MHC restricted peptide presentation by the APC, necessitates a physical interaction and stable adhesion between the APC and the TCR. The TCR is a clonally distributed receptor meaning that the T-cells with different antigen specificity have different TCRs. Signal transduction after peptide binding happens not only through the TCR alone but also through the noncovalently linked TCR-associated invariant protein called CD3 and  $\zeta$  proteins which together form the TCR complex. Signaling through this TCR complex constitute the first signal.

Apart from the TCR complex, the T-cells also express various other surface receptors or molecules which do not bind or recognize antigen but participate in signaling concurrent with the signal through the TCR complex for full activation of the T-cell. This constitutes the co-stimulatory second signal for T-cell activation. These molecules are collectively called the accessory molecules, which other than functioning as co-stimulatory molecules also take part in cell adhesion (for stabilizing the TCR-APC binding), regulate migration and homing to specific sites and also take part in effector functions. The co-stimulatory or accessory molecules on the T-cells have certain common characteristics:

- They bind to their ligands present on the surfaces of APCs, endothelial cells, B-cells and extracellular matrix.
- Unlike the TCR and BCR, these molecules are nonpolymorphic, i.e., they are identical on all T-cells.
- On ligand binding, they transduce signals to the T-cell leading to either T-cell activation (e.g., B7-CD28 interaction) or inhibition [e.g., B7-CTLA (cytotoxic T-lymphocyte antigen)-4 interaction].

**CD4 and CD8 coreceptors** The CD4 and CD8 molecules bind to the nonpolymorphic regions of the MHC molecules concurrent with the TCR-peptide-MHC complex binding and signal transduction, and also strengthen the T-cell APC binding. CD4 binds to MHC Class II associated peptide whereas CD8 binds to Class I-associated peptide. Since T-cells express CD4 and CD8 molecules exclusive of each other, this segregation ensures handling of extracellular microbes by the predominantly cytokine producing CD4 cells and of intracellular microbes by CD8 cytotoxic T-cells.

**CD28 and CTLA-4 coreceptors** The best defined co-stimulation of T-cells which provides the second signal are a pair of related proteins, B7-1 (CD80) and B7-2 (CD86) which are expressed on the surface of professional APCs. The corresponding ligands on T-cells are CD28 and CTLA-4 (CD152). While signaling through the former leads to T-cell activation and proliferation, binding of CTLA-4 by B7 leads to inhibition of T-cell activation and termination of T-cell responses.

**Other coreceptors** CD45, CD2, CD40L, FasL (Fas ligand), LFA-1 (lymphocyte function-associated antigen 1) [which bind to ICAM-1 (intercellular adhesion molecule 1)], VLA-4 (very late antigen-4) which bind to vascular cell adhesion molecule.

When APCs first encounter an antigen either at the portal of entry or the draining lymph node, they process the antigen and present it to the naïve T-cells (either CD4 or CD8) and leads to their activation. The consequences of this activation are as follows:

- **Cytokine production** Signaling through the TCR and the co-receptors leads to a cascade of signaling, resulting in activated transcription factors causing cytokine gene transcription and protein synthesis. One of the earliest cytokines produced by a naïve T-cell after antigen binding is IL-2 which acts as a

growth and differentiation factor not only for other T-cells but also in an autocrine manner, promote its own differentiation and growth. This autocrine effect is further enhanced by a concomitant upregulation of the IL-2 receptor on the T-cell.

- **Proliferation of the antigen specific clone** (clonal expansion) as a result of the autocrine loop involving the IL-2 and IL-2 receptor.
- **Differentiation into effector cells** which subsequently enter the circulation and again get activated on encountering the specific cognate antigen. Antigen binding to an effector cell, unlike the naïve T-cell, however, leads to effector functions. The effector CD4 cells secrete an array of cytokines whereas activation of the CD8 effector cell leads to cellular cytotoxicity and elimination of the infected target cell. Depending upon the cytokine milieu, naïve CD4 cells differentiate into either Th1 (T helper type 1) cells (under the influence of IL-12 produced mainly by activated macrophages and dendritic cells), or Th2 suppressor cells (in response to IL-4 which may be produced by the T-cells themselves). The Th1 differentiation pathway is principally in response to microbes that either infect or activate macrophages which produce large amounts of IL-12 or stimulate NK cells to produce IFN- $\gamma$  which in-turn induce IL-12 secretion by macrophages. IL-12 acts through the activation of STAT1 (signal transducer and activator of transcription 1), STAT4 and T-bet transcription factor for Th1 differentiation. Th2 differentiation on the other hand occurs in response to helminths and allergens, which cause chronic T-cell activation without much macrophage activation. It is dependent on IL-4, which functions by activating the transcription factor STAT6 and GATA3 (*guanine adenine thymine adenine* sequence-binding protein 3). Similarly,

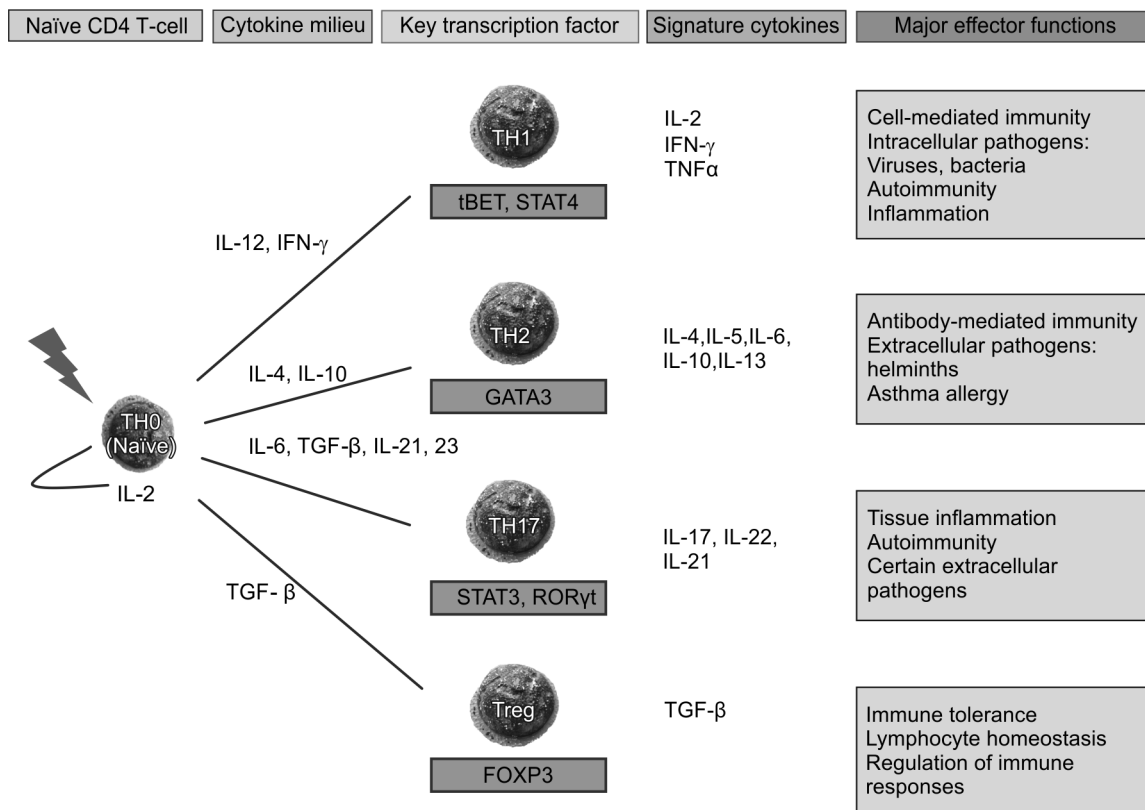

under the influence of IL-6 and TGF- $\beta$  (transforming growth factor-beta), the naïve T-cells differentiate into IL-17 producing Th17 cells through STAT3 and retinoid-related orphan receptor gamma t (ROR $\gamma$ t) transcription whereas in absence of IL-6 and presence of only TGF- $\beta$ , they differentiate into T regulatory cells through FOXP3 (forkhead box protein 3) transcription (Fig. 1).

- **Development of memory cells** This T-cell population is responsible for the accelerated secondary immune response on re-exposure to the same antigen.

### B-cell Activation

Antigen binding to the surface BCR (IgM and IgD) of the resting, mature B-cell, causes BCR cross linking which then transduces signals through the BCR associated Ig- $\alpha$  and Ig- $\beta$ . Ig- $\alpha$  and Ig- $\beta$  are disulfide linked to one another and noncovalently associated with the surface Ig and similar to the CD3- $\zeta$  in the TCR, constitute the BCR receptor complex. BCR cross-linking brings in close proximity the cytoplasmic domains of Ig- $\alpha$  and Ig- $\beta$  containing immunoreceptor tyrosine based activation motifs (ITAMs), phosphorylation of which brings about downstream signaling resulting in activation of transcription factors like Fos, Jun, NF- $\kappa$ B and Myc leading to functional activation of B-cells. The second co-stimulatory signal to the B-cells occurs through complement C3d binding to the complement receptor 2 (CR2) expressed as a membrane bound complex composed of CR2, CD19 and CD81.

Binding of the cognate antigen to the surface BCR brings about proliferation, and increased expression of HLA Class II, B7-1 and B7-2. The latter renders the B-cells capable of activating Th cells through binding to CD28 which subsequently activates the T-cell. Th cells then secrete cytokines which in-turn helps

**Figure 1** Differentiation of naïve CD4 T-cells into various effector subsets based on the cytokine milieu and key transcription factor  
 Abbreviations: IL, interleukin; IFN, interferon; TGF, transforming growth factor; STAT, signal transducer and activator of transcription; ROR $\gamma$ t, retinoid-related orphan receptor gamma t; FOXP3, forkhead box protein 3; TNF, tumor necrosis factor).

B-cell clonal expansion, isotype switching, affinity maturation and differentiation into memory B-cells. B-cell activated Th cells also express CD40 ligand (CD40L, CD154) which binds to CD40 on the B-cell and brings about B-cell maturation and isotype switching.

## Effector Phase

### Effector Mechanisms of Cell-mediated Immunity

A cell-mediated immune response is aimed at controlling two distinct situations: (a) handling microbes that reside and proliferate within the phagocyte and (b) handling microbes that infect various cell types including nonphagocytic cells and replicate in the cytosol. The former requires enhancing the phagocytic potential for microbe elimination and is brought about by Th1 cells. The latter situation requires, since the infected cell lacks phagocytic function, killing of the infected cell to eradicate the reservoir and this is brought about by CD8+ cytotoxic T-cells. The Th2 subset is required for handling large extracellular parasites like helminths (described subsequently).

**T-cell-mediated macrophage activation and the delayed type hypersensitivity** Extracellular antigen or microbes processed through the phagolysosomal machinery bring about activation of HLA Class II restricted CD4 T-cells which differentiate into Th1 and Th2 subsets. This Th1 polarization is mediated by IL-12 produced by macrophages and dendritic cells in response to: (a) microbial products such as lipopolysaccharide (LPS); (b) CD40 ligation with CD40L and (c) in response to IFN- $\gamma$  produced by NK cells. The Th1 effectors in turn produce more IFN- $\gamma$ , also contributed by the CD8 T-cells, which stimulates microbicidal function of the macrophages and increased IL-12 secretion providing an amplification loop. The activated T-cells also produce TNF- $\alpha$  and lymphotoxin which promote leukocyte recruitment and inflammation which may cause tissue injury. Activated macrophages kill phagocytosed as well as extracellular microbes by producing microbicidal reactive oxygen intermediates, nitric oxide and lysosomal enzymes.

**CD8 T-lymphocyte-mediated cytolysis** Naïve CD8 T-cells are activated by MHC Class I-associated peptides derived from intracellular microbial proteins together with a second co-stimulatory signal. The principal mechanism of cytotoxic T-lymphocyte (CTL)-mediated cytolysis is the delivery of cytotoxic granule protein to the target cell. The two granule proteins that are most important for cytolysis are perforin and granzyme.

A second mechanism of cytolysis employed by CTLs is mediated by FasL which is expressed upon CTL activation. FasL binds to Fas, which is expressed by many cell types. This interaction leads to activation of caspases and apoptosis of the target cell. Whereas perforin or granzyme pathway is the principal mechanism of cytolysis by CD8 T-cells, FasL may be more important for the cytolytic activity of some CD4 cells.

**Role of Th2 cells in cell-mediated immunity** The Th2 derived cytokines IL-4, IL-10 and IL-13 inhibit macrophage activation and the associated inflammatory response. Th2 cells thus limit the injurious consequences of CMI. Th2 cells, however, also induce inflammatory reactions that have a prominent eosinophil and mast cell component. This type of a response is required for the elimination of helminthic and ectoparasitic infestations to which macrophage-mediated responses are ineffective. IL-4 stimulates the production of helminth specific immunoglobulin E (IgE) antibodies which opsonize the parasite. IL-5 activates eosinophils which bind to the IgE coated helminths by virtue of their Fc receptors (FcRs) for IgE and release their granule content. The major eosinophil granule

proteins that are involved are major basic protein and major cationic protein, which are capable of destroying the tough integuments of helminths. The granules of mast cells which are released in a similar manner contain vasoactive amines, cytokines such as TNF and lipid mediators that induce inflammation.

### Effector Mechanisms of Humoral Immunity

Most of the effector functions of antibodies are mediated by the heavy chain constant region, with different heavy chain isotypes varying in their efficiency of carrying out the effector functions. This, however, requires binding of the antigen to the variable region of the Ig molecule thus ensuring that the effector functions are activated only on antigen encounter.

The various mechanisms by which antibodies function in host defense are:

- **Neutralization** by binding to the microbes or toxin and making them unavailable for binding to their cellular receptors either by *steric hindrance* or by *allosteric* effects.
- **Opsonization** or coating of the microbes with antibodies and promoting their phagocytosis by binding of the Fc portions of the antibody to the FcR on the phagocyte. Of the FcRs of different Ig isotypes, the ones that are most important for phagocytosis are FcRs for IgG antibodies called Fc $\gamma$  receptors (Fc $\gamma$ R). The major high affinity Fc $\gamma$ R is Fc $\gamma$ RI (CD64) which binds to human IgG1 and IgG3 strongly and weakly to IgG2 and IgG4. Binding of the Fc $\gamma$ RI (and other FcRs) also brings about activation of the phagocyte. Apart from antibodies, opsonization is also carried out by complement components C3b, iC3b and C4b through the CRs on macrophages and neutrophils.
- **Antibody-dependent cellular cytotoxicity** FcRs on NK cells, called Fc $\gamma$ RIII (CD16) binds to IgG antibodies attached to cells, resulting in NK cell-mediated lysis of the cell through release of perforin and granzyme from granules. Since Fc $\gamma$ RIII is a low affinity receptor and bind only to antibodies that are clustered on the target cell surface, free IgG in the serum does not activate the NK cells. Apart from release of perforin and granzyme, engagement of the Fc $\gamma$ RIII also induces large amount of IFN- $\gamma$  secretion by NK cells which activate macrophages.
- **Complement-mediated cytolysis** Binding of complement C3b to a target cell leads to activation of late complement components and formation of membrane attack complex which cause lysis of the target cell.

### IN A NUTSHELL

1. Immune system is an intricately coordinated and complex biological system.
2. Innate and adaptive immunity are two principal components of the immune system.
3. Innate and adaptive immune mechanisms are not mutually exclusive and there is a great deal of crosstalk between these components.
4. Immune system is a proverbial double-edged sword. An exaggerated and inappropriately regulated immune response can lead to autoimmune diseases whereas a deficient immune response can lead to immunodeficiency diseases although there are overlaps.
5. Maintenance of immune homeostasis and a stringently regulated immune response is perhaps as important as the immune system itself.

## Chapter 4.2

# Laboratory Diagnosis of Immune-mediated Diseases

Biman Saikia, Deepti Suri

The clinician requiring an immunological assessment of the patient requires few basic questions to be addressed: what test to use, how to use the test, the meaning of a specific result and what action to take on receipt of a result. This requires a thorough analysis of the clinical information and an adequate and sufficient indication for evaluation. Autoimmune diseases, allergy and asthma, organ and bone marrow transplantation, lymphoid and plasma cell malignancies, and primary and secondary immune deficiencies, have all provided enough challenges and opportunities for immunologic evaluation.

Immunologically, mediated disorders, especially autoimmune diseases are diagnosed in light of clinical symptoms and not test results. Testing is complex and the following issues should always be considered:

- Very few tests provide an absolute diagnostic interpretation and needs to be correlated in terms of clinical presentation.
- Large proportions of *apparently normal* individuals may test positive for some tests, e.g., antinuclear antibodies (ANAs).
- Negative results may not exclude disease conditions (e.g., seronegative rheumatoid arthritis).
- Test results alone cannot be used to guide treatment.
- Many of these tests are carried out only in specialized laboratories and are costly.

For the ease of discussion, immunological laboratory investigations can be broadly categorized into serologic and cell/tissue-based assays and considered under different disease heads. The subsequent sections outline the common laboratory techniques employed in clinical practice under similar heads.

## AUTOIMMUNE DISEASES

Most autoimmune disorders are characterized by autoinflammation. Elevations in markers for inflammation provide initial clues to the diagnosis of these disorders. Complete blood count reveals anemia, polymorphonuclear leukocytosis, thrombocytosis and an increase in erythrocyte sedimentation rate. Quantitative C-reactive protein is an important marker of inflammation and helps in monitoring the disease. Serological assays are aimed at detecting antibodies in the serum and require a clotted peripheral blood sample without any evidence of in vitro hemolysis.

## Antinuclear Antibodies

Antinuclear antibodies (ANA) are serologic hallmarks of patients with systemic autoimmune disease. ANAs were initially discovered in 1940 using the lupus erythematosus (LE) cell test on buffy coat samples. The LE cell is a phagocyte with an ingested nucleus with disrupted chromatin because of binding of the ANAs giving it a homogeneous appearance. LE cell test is, however, cumbersome and has largely been replaced by detection of autoantibodies in serum. Detection of these autoantibodies has both diagnostic as well as prognostic implications. The ANAs help establish diagnosis of certain autoimmune diseases when suspected clinically, subclassify patients with established autoimmune disease and used to monitor disease activity. Though less specific, ANA testing has a very high negative predictive value and helps to exclude disorders with uncertain clinical findings.

## Diseases Associated with a Positive Antinuclear Antibody

A positive ANA is an essential component of the definition of some systemic autoimmune disorders, such as systemic lupus erythematosus (SLE), but can also be found in association with many autoimmune disorders not defined by these antibodies (**Table 1**). They can be encountered in a variety of infections such as mononucleosis, hepatitis C infection, *Mycoplasma* infection, subacute bacterial endocarditis, tuberculosis, human immunodeficiency virus infection, and some lymphoproliferative disorders. Their presence does not mandate the presence of illness, since they can also be found in 5–10% of otherwise normal individuals. False positive ANAs (i.e., ANAs in the absence of autoimmune disease or known antigenic stimuli) are more commonly seen in women and in elderly patients, though in low titers.

Certain drugs can induce asymptomatic ANA positivity and drug-induced lupus. Important ones are procainamide, hydralazine, minocycline, penicillamine, isoniazid, quinidine and antitumor necrosis factor agents such as infliximab. Medications identified as probable causes include anticonvulsants such as phenytoin, carbamazepine, ethosuximide, antithyroid drugs, and antimicrobials such as rifampicin, nitrofurantoin, sulfonamide,  $\beta$ -blockers, captopril, and interferon gamma. Differentiating drug-induced lupus and SLE is a clinical challenge. Serious organ involvement is rare in drug-induced lupus and in presence of hypocomplementemia and double-stranded deoxyribonucleic acid (dsDNA) antibodies. Antihistone antibodies are marker for drug-induced lupus.

## Techniques in ANA Testing

Two major techniques employed for detection of ANAs are indirect immunofluorescence (IIF) and enzyme-linked immunosorbent assay (ELISA). Both techniques utilize the principle of antibody binding to antigens in a tissue substrate (IIF) or immobilized purified antigen bound to a solid support like polystyrene microtiter wells (ELISA). The most common substrate used for detection of ANAs by IIF is human epithelial type 2 (HEp-2) cells derived from a laryngeal carcinoma cell line, and offers the advantage of a large nucleus for evaluation of the different targets of ANA. Incubation of the patient's serum with the HEp-2 cells allows binding of the

**Table 1** Diseases associated with positive antinuclear antibodies

Systemic autoimmune disorders	Percentage positivity
Systemic lupus erythematosus	93
Scleroderma	85
Mixed connective tissue disease	93
Polymyositis/dermatomyositis	61
Rheumatoid arthritis	41
Pauciarticular juvenile idiopathic arthritis	71
Sjögren syndrome	48
Drug-induced lupus	100
Specific organ autoimmune disease	Percentage positivity
Hashimoto thyroiditis	46
Graves disease	50
Autoimmune hepatitis	63–91
Primary biliary cirrhosis	10–40
Primary autoimmune cholangitis	100
Idiopathic pulmonary arterial hypertension	40

ANAs to the nucleus which is then detected by using an antihuman immunoglobulin G (IgG) labeled with a fluorescent dye (most commonly fluorescein isothiocyanate) and examined under a fluorescent microscope.

### Types of ANA

The various patterns that can be discerned in HEp-2 substrates are homogeneous (or diffuse), speckled, nucleolar, and a combination of the above (mixed patterns). The recommended dilution of the serum for routinely detected ANAs is likely to vary with different reference population and it is important for each testing laboratory to determine the ideal dilution for their population by testing appropriate number of healthy individuals. Within these broad patterns are more patterns, e.g., the centromeric, and multinuclear (6–8) dot, oligonuclear (1–3) dot patterns are distinct speckled patterns. Nucleolar pattern can be further seen as diffuse nucleolar or speckled nucleolar patterns. Other rare patterns that can be seen are antibodies against mitotic spindle, midbody, and antacentriolar antibodies. The various ANA specificities associated with different ANA patterns are illustrated in **Table 2**.

Apart from ANAs, various antibodies against the cytoplasmic components, such as antimitochondrial antibodies, antigolgi antibodies, antiribosomal (ribosomal P protein) antibodies, can be easily discerned in HEp-2 cells.

Detection of ANA by IIF (**Figs 1A to F**) is based on recognition of staining patterns which are associated with certain ANAs and since ANAs of multiple specificities can give rise to the same pattern, a positive test by IIF requires further analysis either by immunoblotting techniques or specific ELISA to discern the ANA specificity. Immunoblots use either purified or recombinant antigens blotted onto nitrocellulose strips in the form of dots or line assays together with inbuilt negative and positive controls and give information on the ANA specificity on a single strip.

Commercially available ELISAs for specific ANAs, e.g., dsDNA, Smith, SSA/Ro, SSB/La, etc., can be used for ANA specificities. ELISA for generic ANA can be used for screening in lieu of IIF. Generic ELISA kits use a cocktail of antigens to coat the microtiter wells. Though the sensitivity as well as the specificities of the generic ELISAs are similar to ANA by IIF, ANA ELISA loses out on some vital information about the various patterns which help to subclassify the patients. Whereas IIF is reported as intensity of fluorescence graded as + to +++, ELISAs are reported as optical density (OD) readings above the cut off calculated on the basis of the positive control and the sample OD.

### Antineutrophil Cytoplasmic Antibodies

Antibodies directed against neutrophil cytoplasmic antigens were first described in patients with pauci-immune glomerulonephritis in 1982 and were actually believed to be associated with Ross River virus infection. By 1985, however, antineutrophil cytoplasmic antibodies (ANCA) had been linked to granulomatosis with polyangiitis (Wegener's granulomatosis), abbreviated as GPA. Within several years, a relationship among ANCA, GPA, microscopic polyangiitis, and *renal-limited* vasculitis (pauci-immune glomerulonephritis without evidence of extrarenal disease) was established. The ANCA testing currently plays a critical role in the diagnosis and classification of vasculitides, even as debate about their ultimate importance in the pathogenesis and pathophysiology of these conditions continue.

Antineutrophil cytoplasmic antibodies are directed against granule proteins of neutrophils and are found as a marker of the ANCA-associated vasculitides (**Table 3**). Detection of the ANCAs hence requires human neutrophil as the substrate for IIF studies. ANCA testing is carried out on O-positive neutrophil spots on glass slides fixed in ethanol. Ethanol fixation leads to redistribution of the positively charged granule protein myeloperoxidase (MPO) toward the negatively charged nuclear membrane leaving proteinase-3 (PR3) unaffected. This gives rise to two distinct patterns of staining in IIF: the cytoplasmic pattern (cANCA) with antibody specificity to PR3 and perinuclear pattern (pANCA) directed against MPO (**Figs 2A and B**). The former pattern is characteristically described as cytoplasmic staining with interlobular accentuation to denote the characteristic staining intensity in between the nuclear lobes, and this helps differentiate this pattern with the nonspecific atypical ANCA pattern which can arise due to antibodies directed against a variety of antigens such as lactoferrin, cathepsins, etc. Similar to ANAs, ANCA specificities can be further confirmed by specific ELISAs for MPO and PR3 or by using immunoblots.

### Antimitochondrial Antibodies, Antiliver-Kidney Microsomal Antibodies, Antiparietal Cell Antibodies, Antismooth Muscle Antibodies, Antiendomysial Antibodies

Indirect immunofluorescence using frozen sections from a composite tissue block (referred to as composite testing) of rat kidney, stomach and liver is a very helpful screening test for autoimmune disorders. Degree of positivity is reported as + to +++ according to the staining intensity and the location of the positive

**Table 2** Association of indirect immunofluorescence antinuclear antibody patterns with disease

Pattern of ANA	Antigens specificities	Disease associations
Homogeneous (diffuse)	dsDNA	SLE (60–90%)
	Histone	Drug-induced SLE (95–100%)
Speckled	Smith	SLE (20–40%), specific
	U1RNP	MCTD (95–100%)
	SSA/Ro (Ro52 and Ro60), SSB/La	Sjögren syndrome (40–80%)
	Scl-70	PSS, diffuse form (25–75%)
Centromeric	CENP-A/B	PSS (80–90%)
Multiple nuclear (6–8) dots	SP100	PBC (34–42%)
Nucleolar-diffuse	PM Scl-100	PSS (5–10%), PM-DM (50–70%)
Nucleolar-speckled	RNA polymerase I, U3-nRNP/fibrillarin	PSS (36%)

**Abbreviations:** SLE, systemic lupus erythematosus; MCTD, mixed connective tissue disorders; PSS, progressive systemic sclerosis; PBC, primary biliary cirrhosis; PM, polymyositis; DM, dermatomyositis; CENP-A/B, centromere protein A/B; dsDNA, double-stranded deoxyribonucleic acid; nRNA, nuclear ribonucleoprotein.

**Figures 1A to F** Indirect immunofluorescence. (A) Homogenous (diffuse) on HEp-2 cells; (B) Nuclear envelope on rat liver section; (C) Speckled pattern on HEp-2 cells; (D) Centromeric pattern on HEp-2 cells; (E) Multiple nuclear dots on HEp-2 cells; (F) Nucleolar (diffuse) on HEp-2 cells

**Figures 2A and B** Indirect immunofluorescence on O-positive neutrophils. (A) Perinuclear pattern (pANCA); (B) Cytoplasmic pattern (cANCA) with typical interlobular accentuation

**Table 3** Disease association of ANCA, percentage of occurrence and antigen specificity

Disease	IIF-ANCA	Antigenic target
Granulomatous angiitis	cANCA (75–80%)	PR3
	pANCA (10–15%)	MPO
Microscopic polyangiitis	cANCA (25–30%)	PR3
	pANCA (50–60%)	MPO
Churg-Strauss syndrome	cANCA (25–30%)	PR3
	pANCA (25–30%)	MPO
Systemic lupus erythematosus	pANCA (20–30%)	Lactoferrin
Ulcerative colitis	pANCA (40–70%)	Lactoferrin, cathepsin, MPO, BPIP

**Abbreviations:** IIF, indirect immunofluorescence; ANCA, antineutrophil cytoplasmic antibodies; cANCA, cytoplasmic ANCA; pANCA, perinuclear ANCA; PR3, proteinase-3; MPO, myeloperoxidase; BPIP, bactericidal/permeability-increasing protein.

staining gives the antigen specificity. Recommended dilutions for testing are 1:40 for adults and 1:20 for children. The pattern of positivity and their inference is shown in **Table 4**.

### Antibodies for Diagnosis of Dermatologic Disorders

Indirect immunofluorescence for dermatologic disorders is most commonly required for diagnosis of the bullous disorders, viz. pemphigus and pemphigoid. The typical tissue substrate used can be monkey esophagus or normal human skin. Incubation of the patient's sera containing antibodies against desmoglein 1 and 3 in pemphigus leads to an intracellular *basket weave* or *fish-net* staining pattern in the epithelium whereas in the pemphigoid group of disorders, antibodies against the hemidesmosomes (BP-160, BP-180) or collagen (type VII) leads to a linear pattern of staining along the basement membrane zone. The intensity of staining is graded as + to +++. The antibody specificity can then be confirmed by performing specific ELISAs for desmoglein 1 and/or 3, BP-160, BP-180, or type VII collagen, as the situation may demand.

**Table 4** Patterns of indirect immunofluorescence positivity, associated antibodies and disease

Pattern of IIF positivity in composite section	Associated antibodies	Disease association
Granular cytoplasmic positivity in proximal convoluted tubules of kidney, parietal cells and smooth muscles of stomach	Antimitochondrial antibodies	Primary biliary cirrhosis, PBC-AIH overlap
Granular cytoplasmic positivity in hepatocytes and kidney tubules. Negative staining in parietal cells	Liver, kidney microsomal antibodies	AIH type II
Granular cytoplasmic positivity in parietal cells only	Parietal cell antibodies	Autoimmune gastritis
Smooth muscles of stomach, blood vessels and glomerular mesangium	Antismooth muscle actin	AIH type I
Nuclei	ANAs	As ANAs
Basket weave staining of smooth muscles of stomach	Antiendomysial antibodies	Gluten hypersensitivity (celiac disease)

Abbreviations: PBC, primary biliary cirrhosis; AIH, autoimmune hepatitis; ANAs, antinuclear antibodies.

### Other Specific Antibodies

Antitissue transglutaminase (IgA or IgG), antigliadin antibodies (for celiac disease), anticitrullinated peptide antibodies (for rheumatoid arthritis and related disorders), anti-GAD65 (for type I diabetes), antithyroid peroxidase and antithyroglobulin (for autoimmune thyroiditis) can be performed easily using commercially available ELISA kits.

### Cell/Tissue-based Assays

Cell-based assays for diagnosis of autoimmune disorders are restricted to assessing susceptible human leukocyte antigen (HLA) type associations, e.g., HLA B27 (for ankylosing spondylitis, anterior uveitis), HLA B5 (*Behçet* disease), HLA DQ2/DQ8 for celiac disease. This can be done by using complement dependent cytotoxicity assays, flow cytometry or by DNA-based assays like sequence-specific primer (SSP) and sequence-specific oligonucleotide probes (SSOP). Rare situations may require looking at cytokine secretion assays by Enzyme-Linked ImmunoSpot, but would be mostly of academic or research significance.

Tissue-based assays, e.g., skin biopsy and kidney biopsies for direct immunofluorescence require fresh tissue in holding buffer (never in formalin) for demonstration of antigen-antibody complex deposition in tissues. Various dermatologic conditions may include pemphigus (basket-weave pattern with IgG and/or C3 deposits), bullous pemphigoid (linear IgG and/or C3 in basement membrane), IgA in linear IgA disease, IgA in dermatitis herpetiformis (deposits in papillary dermis), IgA vasculitis in Henoch-Schönlein purpura, and lupus band (IgM, IgG, IgA and C3 in a granular pattern in the upper dermis) in lupus/discoid lupus erythematosus.

## ALLERGY AND ASTHMA

Most of the symptomatic allergies involve respiratory, skin and gastrointestinal tract. A detailed clinical analysis including history and physical examination related to these systems is the key to diagnosis of allergy. A variety of tests, e.g., total serum IgE levels, skin prick test (SPT), intradermal skin test, patch test, specific IgE tests, double-blind placebo controlled oral food challenge test (OFC), examination of tissue and secretions for eosinophils and certain biochemical mediators, e.g., mast cell tryptase, eosinophil cationic protein, basophil activation, etc., are the mainstay of allergy testing. Test selection is based solely on clinical setting, e.g., oral challenge test is most suited for food allergy, patch test for contact dermatitis or any other cell-mediated allergy. The most commonly used and clinically valuable tests are SPT, patch test, OFC and allergen-specific IgE antibodies in serum. Broadly, these tests may be divided into in vitro and in vivo allergy tests (**Table 5**).

### In Vitro Tests: Serology

Total serum IgE and allergen-specific IgE by ELISA or other immunoassays are frequently ordered in suspected allergy. Total IgE levels are, however, nonspecific as raised levels may be present in parasitic, fungal, malignancy or rare disorders such as hyper-IgE syndrome. Hence, allergen-specific IgE levels are most useful in vitro test.

A number of test systems are available to measure specific IgE. Enzyme immunoassay or fluoroimmunoassays are commonly used. Hundreds of allergens such as weeds, trees, pollen, mold, food, and animal dander may be detected in a single blood sample. Sensitivity and specificity of specific IgE is good (70–80%), though testing is bit costly. Hence, though in vitro tests are more useful than in vivo tests, they may be reserved for those patients who cannot be tested by in vivo methods.

### In Vivo Tests

#### Skin Prick Test

This test is widely used in inhalant, food, drug and venom allergies for detection of allergen-specific IgE antibodies because of its high sensitivity, rapidity of results and low cost. It is performed by injecting a drop of allergenic extract into the epidermis, usually forearm or back, at an angle of 45°. For each allergen, a separate prick is made. After about 1 minute of skin prick, the extract is wiped off and after 15–20 minutes prick site is examined for development of wheal and flare response. The largest and smallest dimensions are added and divided by two. The diameter is compared to that produced by histamine which is used as a negative control. Most of the reactions positive for allergy are more than 3 mm in diameter. SPT is highly sensitive for most of the type I hypersensitivity reactions.

#### Patch Test

It is another similar test used in delayed hypersensitivity reactions, e.g., contact dermatitis, latex allergy. In this, rather than making multiple skin pricks, a patch containing tiny quantities of several allergens in individual squares or round chambers are applied either on back or forearm. The patch is kept in place for about 48 hours. Thereafter, it is removed and reading is taken in a similar manner to SPT.

#### Oral Food Challenge (OFC) Test

Though history suggesting an immediate allergic response along with positive specific IgE test is sufficient to establish food allergy without OFC, it is considered a gold standard for confirmation and monitoring of food induced hypersensitivity reactions. Nonetheless non-IgE mediated food allergies, i.e., food protein-

**Table 5** Modes of allergy testing

<i>Skin prick test</i>	<i>Patch test</i>	<i>Oral food challenge test</i>	<i>Total IgE</i>	<i>Specific IgE</i>
<i>In vivo</i>			<i>In vitro</i>	
<i>Done by physician capable to deal anaphylaxis</i>			<i>Done in laboratory</i>	
<i>Any allergy</i> Type I HS 15–20 min C/I: Eczema, patient on steroids or antihistamines, dermatographism, hypersensitive, etc. Only few allergens can be tested at a time Cheaper, faster Detailed history required ↑ Sensitive Specific Semiquantitative, Gold standard	<i>Skin allergy</i> Type IV HS 2–4 days C/I: Eczema Few allergens are tested Slow History required Sensitive, Specific Semiquantitative, excellent for cell-mediated allergy	<i>Food allergy</i> Type I HS/mixed Minutes to hours Important in mixed or non-IgE reactions Suspected allergen eliminated from diet Cheaper, slow History required Sensitive ↑↑ Specific Gold standard	<i>Any allergy</i> Type I HS Variable None Allergens cannot be tested Slightly longer History required Nonspecific Good for screening only	<i>Any allergy</i> Type I HS 2–4 hours None, safer, no interindividual variations Several allergens can be tested at a time Costly, slightly longer Detailed history and total IgE required Sensitive ↑ Specific Quantitative, excellent alternative to SPT

Abbreviations: IgE, immunoglobulin E; HS, hypersensitivity; SPT, skin prick test; C/I, contraindication(s).

induced enterocolitis and food allergy due to mixed immune responses requires OFC. Blinded OFC, in which challenge food is mixed with other food to hide its taste and texture, is given in two sessions one with active food and second with placebo by a third party (double-blind). Symptoms such as urticaria, vomiting, angioedema, wheezing, etc., are usual signs in a positive OFC.

## PRIMARY AND SECONDARY IMMUNE DEFICIENCIES

### General Principles

Always evaluate age matched-unrelated healthy control sample simultaneously for assay evaluation. Tests, especially functional assays should be performed on fresh samples. Whereas absence of protein expression (by flow cytometry) indicates disease, its presence does not rule out a disease because mutations can give rise to a nonfunctional protein which is nevertheless expressed. Functional studies are hence required. Moreover, not all mutations are pathogenic, and some may represent gene polymorphisms. Hence, population studies are important for deducing pathogenicity. Though confirmation of a primary immunodeficiency (PID) comes from genetic studies, certain entities such as combined immune deficiency (CID) warrant urgent treatment without waiting for a genetic diagnosis.

### Serology

Human immunodeficiency virus infection must be excluded in all cases of suspected immunodeficiency. Evaluation of patients with putative antibody deficiency requires measurement of total serum immunoglobulins (IgG, IgM, and IgA), IgG subclasses (IgG1, G2, G3, and G4), and assessment of antibody response to vaccination with both protein, viz. tetanus, and diphtheria toxoid and polysaccharide antigens (pneumococcal polysaccharide vaccine). Apparently, normal IgG serum levels can be detected during the first 2–3 months of life, even in the face of a severe antibody defect because at this age, most of the serum IgG is of maternal origin. For the same reason, antibody deficiency disorders do not present

during infancy and become symptomatic only after the maternal antibody levels gradually wane off. Various abnormalities in serum immunoglobulin levels and their disease associations are listed in **Table 6**.

Very low levels of serum IgG and IgA, with normal to increased serum IgM levels, may indicate a defect in class switching from IgM to IgG and IgA, the so called class switch recombination (CSR) defects. They can be caused either by activation-induced cytidine deaminase or uracil-DNA glycosylase deficiency (intrinsic B-cell defects) or CD40L or CD40 (due to impaired cross-talk between T and B lymphocytes). Though commonly referred to as hyper-IgM syndrome, majority of patients have normal serum IgM levels. The CSR defects usually present with a combined immunodeficiency like picture and presents earlier than common variable immunodeficiency.

Determination of serum IgG subclasses is of limited value on its own unless supplemented by the assessment of specific antibody titers, particularly, antibodies to tetanus and diphtheria toxoids, a measure of antibody response to protein (T-dependent) antigens. Pneumococcal polysaccharide vaccine should be used to test antibody response to polysaccharide (T-independent) antigens. Measurement of hemolytic activity of the classical (CH50) and alternative (AP50) pathways of complement activation, as well as of C3 and C4 levels, might guide in the diagnosis of complement deficiencies. Other assays may include mannan-binding lectin assay, enzymes such as adenosine deaminase, and purine nucleoside phosphorylase [severe combined immunodeficiency (SCID)].

### Cell-based Assays

The absolute neutrophil count (ANC) is markedly reduced in all forms of severe congenital neutropenias. If ANCs show periodicity, counts should be evaluated once a week for 6 consecutive weeks to identify possible decreases in the neutrophil count for documenting cyclic neutropenia. Flow cytometric assessment of surface markers of various lymphocyte subsets, intracellular signaling molecules and functional assessment of cell subsets forms the mainstay of PID diagnostics in the present era (**Tables 7 and 8**).

**Table 6** Various abnormalities in serum immunoglobulin levels and their disease associations

<i>Ig isotypes affected</i>	<i>Probable diagnosis</i>	<i>Confirmation</i>
Low IgG, IgA, IgM	Agammaglobulinemia • X-linked, common • AR, rare D/D: Transient hypogammaglobulinemia of infancy	B-cell numbers (CD19, CD20)
Low IgG with low IgM and/or IgA	CVID	B-cell numbers (CD19, CD20) B-cell subsets (CD21, CD27, sIgM, sIgD, CD38, CD138) Antibody response to pneumococcal polysaccharide vaccine
Low IgA, IgG with normal or increased IgM	Hyper-IgM syndromes	CD40, CD40L
Low IgA	Selective IgA deficiency	-
Low IgM	Selective IgM deficiency	-
Low IgG1 or G2 or G3, or G4	Subclass deficiency	Antibody response to pneumococcal polysaccharide vaccine

Abbreviations: CVID, common variable immunodeficiency; Ig, immunoglobulin; CD, cluster of differentiation; AR, autosomal recessive; sIgM, surface IgM; sIgD, surface IgD; D/D, differential diagnosis.

**Table 7** Protein-specific flow cytometric assays

<i>Disease</i>	<i>Defect</i>	<i>Flow cytometric test</i>
XLA	BTK gene defect	BTK expression on monocytes
LAD type I	$\beta$ chain of $\beta 2$ integrin	CD18, CD11c expression
IPEX	FOXP3 gene	FOXP3
Hyper-IgM syndrome	CD40-CD40L defect	CD40, CD40L
Wiskott-Aldrich syndrome	WAS gene defect	WASp
SCID X-linked	Common $\gamma$ -chain	Common $\gamma$ -chain (CD132)
Familial HLH		Perforin
ALPS	Fas-FasL defect	TCR $\alpha\beta$ +CD4-CD8- (double-negative) T-cells
Hyper-IgE syndrome (AD)	STAT3 gene defect	TH17 cells, pSTAT3 assay
CVID	Various	CD19, BAFFR, ICOS, CD81

Abbreviations: BTK, Bruton tyrosine kinase; CD, cluster of differentiation; CVID, common variable immunodeficiency; SCID, severe combined immunodeficiency; WASp, Wiskott-Aldrich syndrome protein; HLH, hemophagocytic lymphohistiocytosis; ALPS, autoimmune lymphoproliferative syndrome; AD, autosomal dominant; FOXP3, forkhead box P3; STAT3, signal transducer and activator of transcription 3; XLA, X-linked agammaglobulinemia; IPEX, immune dysregulation, polyendocrinopathy, enteropathy, X-linked syndrome; LAD, leukocyte adhesion deficiency; Ig, immunoglobulin; TH, T-helper.

Unexplained lymphopenia in early infancy, especially T-lymphopenia (CD3) is the hallmark of SCID, a medical emergency. Similar to antibody levels, comparison of lymphocyte subsets with age-matched control is very crucial for the diagnosis. Depending on the presence or the absence of T-cell (CD3), B-cells (CD19/20) and NK cells (CD16/56), SCID is classified as T-B- and T-B+ SCID with presence or absence of NK cells. Whereas a typical SCID will present very early in life with various infections, the variants of SCID resulting from hypomorphic gene mutations, which allow some degree of T-cells development, results in a graft versus host disease (GVHD) like presentation. The presence of maternal T-cell engraftment or of residual autologous T-cells in such patients

**Table 8** Functional assays used for the diagnosis of primary immunodeficiency disorders

<i>Assay</i>	<i>Disease association</i>	<i>Flow cytometric test</i>
NK cell cytotoxicity assay	Familial HLH	K562 assay by CFSE, PI staining
Phagocytosis	Various	pHrodo bioParticles phagocytosis assay
Impaired Fas-mediated apoptosis	ALPS	Annexin V, Caspase 3
Lymphocyte proliferation assays to PPD, tetanus toxoid and <i>Candida</i> antigens	Various	3H-thymidine incorporation, CFSE staining
Lymphocyte activation assays	Various	Activation markers: CD69, CD25, HLA-DR

Abbreviations: NK cell, natural killer cell; HLH, hemophagocytic lymphohistiocytosis; PPD, purified protein derivative; CD, cluster of differentiation; HLA, human leukocyte antigen; ALPS, autoimmune lymphoproliferative syndrome; CFSE, carboxyfluorescein succinimidyl ester; PI, propidium iodide.

show a relatively preserved (and even normal) T-lymphocyte count and hence requires a very high degree of clinical suspicion. CD4 lymphopenia and CD8 lymphopenia are other entities that can be picked by flow cytometry.

Antibody deficiency disorders require enumeration of B-cells (CD19, CD20). Patients with X-linked agammaglobulinemia show a virtual absence of mature B-cells and plasma cells, whereas in disorders like CVID, B-cell numbers may be normal or low. B-cell subset analysis (CD19+IgM+IgD+CD27- naive B-cells, CD19+IgM-CD27+ memory B-cells, CD19+CD21+CD38+ transitional B-cells and CD19+CD138+CD27+ plasmablasts) in such cases often reveal varying degrees of maturation arrest. Patients with CD19 deficiency related CVID will show absent B-cells, if CD19 is used alone as a B-cell marker. However, CD20 may reveal a normal number of B-cells in such patients.

Diagnosis of chronic granulomatous disease (CGD) can be easily evaluated by demonstration of reduced/absent oxidative burst due to deficiency of nicotinamide adenine dinucleotide phosphate (NADPH) oxidase activity using quantitative dihydrorhodamine-123 (DHR-123) oxidation by flow cytometry. Patients with X-linked CGD (X-CGD) often demonstrate a severe

defect whereas autosomal recessive CGD (AR-CGD) often have detectable but reduced levels of NADPH activity. Female carriers of X-CGD can be easily picked up using this assay which demonstrates two populations of DHR oxidizing cells. Reduced DHR oxidation can however be seen in other conditions like glucose-6-phosphatase dehydrogenase deficiency, MPO deficiency, glutathione reductase and glutathione synthetase deficiency, and transcobalamin II deficiency; and secondary disorders including diabetes mellitus, burn, trauma, uremia, and malnutrition. Nitro-blue tetrazolium dye reduction test, though still performed at some centers can often be subjective and fails to detect carriers and patients with milder defects.

Genetic analysis of specific mutations is important not only to confirm the diagnosis but also for genetic counseling, carrier detection and prenatal diagnosis. Analysis of messenger RNA and/or protein expression together with functional assays is often required to ascertain pathogenicity of a gene mutation. PID is a rapidly expanding field with newer entities being described continuously, and patients may not fit into a well-defined known entity, and the possibility of a new syndrome or disease should always be kept in mind. Whole exome sequencing has greatly facilitated the identification of newer entities.

## LYMPHOID AND PLASMA CELL MALIGNANCIES

### Serum Protein Electrophoresis

Detection of M component in the serum can be easily done on serum electrophoresis, and densitometric quantification of the serum proteins can be assessed after knowing the total serum protein and albumin fractions biochemically. An urine sample should always be tested along with the serum sample when a plasma cell dyscrasia is suspected, because light chains are totally filtered into the urine and do not appear in the serum, unless the patient has severe renal failure with renal shutdown. Hence for diagnosing light chain disease, examination of the urine is mandatory.

In addition to detection of the M band, serum protein electrophoresis (SPE) gives various other important information useful for clinical assessment of a patient. Presence of a profound hypogammaglobulinemia in association with M component usually indicates a high plasma cell load in the bone marrow replacing the normal Ig producing plasma cells whereas in localized disease (solitary plasmacytoma) or a low plasma cell load, the SPE shows the presence of normal Ig band in the background of M component.

Urine electrophoresis often shows the presence of corresponding serum M component. In addition, light chains (Bence Jones proteins) can be seen in the  $\beta$  region in 30–40% of cases of multiple myeloma. Glomerular involvement resulting in a nephrotic syndrome like picture would reflect in a glomerular proteinuria (presence of albumin band at a stage of selective proteinuria with addition of  $\alpha_1$ ,  $\beta$  and  $\gamma$  components as the proteinuria gets more and more nonselective).  $\alpha_2$  proteins are characteristically not seen even in the face of significant nonselective proteinuria as  $\alpha_2$ -macroglobulin, the major protein component of the  $\alpha_2$  fraction, owing to its large molecular weight is not filtered into the urine. In addition, there is a concurrent increase of the  $\alpha_2$  fraction in the serum owing to its selective retention and also contributed by an increased hepatic synthesis as a part of the acute phase response. The albumin component in the serum will be reduced on the face of a prominent albumin band in the urine, and  $\beta$  fraction increased as a part of hypercholesterolemia seen in nephrotic syndrome. Presence of proteinuria (with bands in  $\alpha$  and  $\beta$  regions) in absence of albumin reflects tubular proteinuria.

## Immunofixation Electrophoresis

It can be used for characterization of the heavy and light chain components of the M-protein by using antisera against IgG, IgA, IgM, IgD, kappa and lambda overlaid onto the electrophoresed gel. Serum  $\beta_2$  microglobulin can be done by nephelometric methods. Serum free-light chain assay is a very useful adjunct to monoclonal gammopathy diagnosis and is more sensitive than SPE or immunofixation electrophoresis. Nephelometry is the method of choice for estimation of free light chains. In addition, this parameter is extremely useful for monitoring of the disease after therapy is instituted.

### Cell/Tissue-based Assays

Fluorescence in situ hybridization for demonstration of translocations, e.g., t(11;14), t(4;14) is a useful adjunct to diagnosis of plasma cell dyscrasias.

## ORGAN AND BONE MARROW TRANSPLANTATION

### Crossmatching

Pretransplant crossmatch can be done by two basic techniques: (a) serologic crossmatch using the complement dependent cytotoxicity and (b) flow cytometry-based assays (both requires freshly isolated peripheral blood mononuclear cells from the donor). While the former has the advantage of being a functional assay looking at actual complement-dependent cellular cytotoxicity (killing of the donor cell), the latter has the advantage of being more sensitive and being able to detect antidonor antibodies irrespective of complement fixation. Results are expressed as percent cell killing in complement-dependent cytotoxicity (CDC) assay and as mean fluorescence shift compared to the negative control in flow cytometric assays. Further modifications to the basic crossmatch by the CDC assay can be made by: (a) crossmatching at 4°C and 37°C; (b) enhancing sensitivity by crossmatching at 4°C and 37°C or other methods; or (c) separate T-cell and B-cell crossmatching.

### Antibody Screening and Panel Reactive Antibodies Testing

Pretransplant screening for pre-existing anti-HLA antibodies can be performed by commercially available ELISA kits, coated with Class I and Class II HLA antigens separately. By using a panel of HLA antibodies, percent panel reactive antibodies (PRA) can be calculated, a high PRA indicating a higher degree of presensitization and vice versa. PRA testing can also be done by more advanced and automated bead-based assays, viz. using the Luminex platform.

### Donor Specific Antibody Testing

Diagnosis of antibody-mediated rejection requires demonstration of donor specific antibody (DSA) as part of the diagnostic criteria. DSA can be detected by ELISA or Luminex-based methods using donor lysate and incubating with recipient's serum.

### Cell/Tissue-based Assays

Human leukocyte antigen typing by serologic technique (CDC method) requires isolation of fresh peripheral blood mononucleated cells (PBMCs) from the recipient by density gradient centrifugation. Tissue types are allocated by incubation of the PBMCs with a panel of known HLA antisera. Since antisera against Class I (HLA A, B, C) are more readily available than Class II sera, for determining Class II HLA types (HLA-DR, -DQ and -DP) DNA-based methods are preferred. DNA-based methods include SSP, SSOP, reverse SSOP and sequence-based typing.

### IN A NUTSHELL

1. Primary immunodeficiency disorders can be diagnosed with relatively simple tests such as complete blood counts, serum immunoglobulins and lymphocyte subset analysis for T, B and NK cells. Clinical suspicion forms the mainstay of diagnosis.
2. Immunologically-mediated disorders, especially autoimmune diseases are diagnosed in light of clinical symptoms and not test results.
3. Clinician should be able to answer these basic questions: what test to use, how to use the test, the meaning of a specific result and what action to take on receipt of a result.
4. A positive ANA test, especially in low titers should be interpreted with caution, and in light of the clinical features.
5. Perinuclear ANCA should not be interpreted on IIF if ANA is strongly positive. Other modalities like ELISA should be used.
6. Cytoplasmic ANCA on IIF should be reported only when the typical pattern with *interlobular accentuation* is observed.

## Chapter 4.3

# Primary Immunodeficiency Disorders

Manisha Madkaikar

Primary immunodeficiency disorders (PIDs) are diverse group of inherited conditions, mostly monogenic, resulting in susceptibility to infections, allergy, autoimmunity and cancer. As more than 200 immunodeficiencies have been described till date affecting various components of immune system, they pose a formidable challenge for both clinicians and scientists. Diagnostic procedures and algorithms are continuously updated as new and new PIDs are added to the existing list every year. While early phenotypic diagnosis helps in initiation of lifesaving treatment, genetic diagnosis becomes important for prognosis, genetic counseling and exploring novel targeted therapeutic interventions.

Though in several developed and developing countries approximate incidence and prevalence of PID is known, the incidence of PID in India is unknown. Based upon the incidence of PID in other countries of 1 in 10,000, it is estimated that the number of PID patients in India is at least 100,000. The diagnosis of PIDs in India is often delayed either because of lack of awareness about PID or unavailability of diagnostic facilities. In addition, endemic nature of multitude of infections, and nutritional deficiencies complicate the suspicion and therefore, diagnosis of PID.

### CLASSIFICATION

The International Union of Immunological Societies has proposed a classification of PIDs which provides a framework to help in the diagnostic approach to patients. In the recent classification, PIDs are classified into 9 major categories according to the component of the immune system primarily involved:

1. Combined T-cell and B-cell immunodeficiencies (CIDs)
2. Other well-defined immunodeficiency syndromes
3. Predominantly antibody deficiencies
4. Diseases of immune dysregulation
5. Congenital defects of phagocyte number and function
6. Defects in innate immunity
7. Autoinflammatory disorders (AIDs)
8. Complement deficiencies
9. Phenocopies of PID.

Under each broad category, there are multiple subcategories with different genetic defects and every year newer diseases are added to the list. However, there are certain common PIDs (< 20% of the listed) which account for more than 90% of the total PIDs diagnosed. This chapter will focus on the important clinical manifestations of common PID and the diagnostic approach for these disorders.

### CLINICAL MANIFESTATIONS

Recurrent infection is the predominant clinical manifestation in these patients. However, even in normal infants and children, the immune system is not fully developed. With exposure to different pathogens, recurrent infections are common in young children. While most children with recurrent infections have a normal immune system, it is important to recognize a child with an

underlying PID from a normal child so that further investigations can be ordered selectively. To help clinicians, the European Society of Immunodeficiencies has suggested 10 warning signs for suspicion of PID. They are listed in **Box 1**.

#### BOX 1 The 10 warning signs for suspicion of primary immunodeficiency disorders

1. Four or more new ear infections within 1 year
2. Two or more serious sinus infections within 1 year
3. Two or more months on antibiotics with little effect
4. Two or more pneumonias within 1 year
5. Failure of an infant to gain weight or grow normally
6. Recurrent, deep skin or organ abscesses
7. Persistent thrush in mouth or fungal infection on skin
8. Need for intravenous antibiotics to clear infections
9. Two or more deep-seated infections including septicemia
10. A family history of primary immunodeficiency disorders.

While evaluating patients for PID, that rather than emphasizing exact numbers of different infections or special definitions of severity; it is more important to consider the infection type, the circumstances under which infections occur, and which organs and tissues they affect. A single episode of infection with any pathogen of low pathogenicity, such as atypical mycobacteria or *Pneumocystis jirovecii* must be investigated for underlying PID after ruling out the possibility of infection with human immunodeficiency virus while most children with respiratory tract infection with common organisms can be observed safely. Many PIDs have unique susceptibilities to some pathogens and/or sites of infections that are listed in **Table 1**. However, this list is far from being complete and there is significant overlap between the infections seen in different categories of PID.

Apart from infections, other clinical manifestations especially age at presentation, pattern of infections, noninfectious manifestations, such as autoimmunity, skin manifestation, skeletal manifestations, malignancies, etc., and family history give an important clue to the underlying immune defect and are crucial for further laboratory evaluation and diagnosis. The important clinical manifestations of common PIDs in each category are summarized here.

### COMBINED T-CELL AND B-CELL DEFICIENCIES

There are 22 different genetic defects listed under this category most common being *X-linked severe combined immunodeficiency* (SCID) or Common gamma chain SCID followed by autosomal recessive (AR) adenosine deaminase (ADA) deficiency and IL7R deficiency. In the most severe form, i.e., SCID, there is a virtual lack of functional T-cells and immune function. Patients with *classical SCID* present within the first year of life usually within first 6 months. Affected infants generally appear well at birth, but within the first few months, demonstrate failure to clear infections and present with persistent respiratory tract or gastrointestinal infections, failure to thrive and, sometimes, apparent food intolerance. Persistent respiratory tract infections either viral and/or due to *Pneumocystis jirovecii*, with bronchiolitis-like signs are common. Persistent viral diarrhea with failure to thrive is an important sign. Extensive persistent superficial candidiasis is more common. However, severe invasive fungal infections are rare. Disseminated *Bacillus Calmette-Guérin* (BCG) infection is another common presentation in Indian patients due to early immunization. Skin lesions (often a mild reticular skin rash, which may be thickened and lichenoid) showing presence of acid-fast

**Table 1** Clues to the presence of primary immunodeficiency

PID	Antibody deficiency	Combined immunodeficiency	Phagocytic defects	Complement deficiencies
Infectious complications	Upper and lower respiratory tract (otitis, sinusitis, pneumonia) GI tract, skin infections sepsis, meningitis	Systemic viral infections gastroenteritis	Respiratory tract Liver of lung abscesses Lymphadenitis GI diseases Urinary tract problems	Meningitis Systemic bacterial infections
<b>Organisms</b>				
Bacteria	<i>Streptococcus pneumoniae</i> , <i>Haemophilus influenzae</i> , <i>Moraxella catarrhalis</i> , <i>Pseudomonas aeruginosa</i> , <i>Staphylococcus aureus</i> , <i>Neisseria meningitidis</i> , <i>Mycoplasma pneumoniae</i>	As for antibody deficiencies, also: <i>Salmonella typhi</i> , <i>Listeria monocytogenes</i> , enteric flora	<i>S. aureus</i> , <i>P. aeruginosa</i> , <i>Nocardia asteroides</i> , <i>S. typhi</i>	As for antibody deficiencies: Especially <i>N. meningitidis</i> in deficiency of later components
Viruses	Enteroviruses	All, especially: CMV, respiratory syncytial virus, EBV, parainfluenza type 3	No	No
Fungi		<i>Candida</i> species, <i>Aspergillus</i> species, <i>Cryptococcus neoformans</i> , <i>Histoplasmosis capsulatum</i>	<i>Candida</i> species, <i>Aspergillus</i> species	
Mycobacteria	No	Nontuberculous, including BCG	Nontuberculous including BCG	No
Protozoa	<i>Giardia lamblia</i>	<i>Pneumocystis jirovecii</i> , <i>Toxoplasma gondii</i> , <i>Cryptosporidium parvum</i>	No	No

Abbreviations: PID, primary immunodeficiency disorders; GI, gastrointestinal; BCG, Bacillus Calmette-Guérin; EBV, Epstein-Barr virus; CMV, cytomegalo-virus.

bacilli on histological analysis with or without slightly deranged liver function are the common manifestations in disseminated BCG disease.

Some SCID patients may present with an eczematous rash, hepatosplenomegaly and lymphadenopathy (features quite different from *classical* SCID) along with recurrent infections. These symptoms are due to residual abnormally active T-cells which either arise in the patient because the genetic defect preventing lymphocyte maturation is not complete (Omenn syndrome) or from maternal lymphocytes that have crossed the placenta and engrafted in the child (SCID with maternal fetal engraftment). There is considerable similarity between the clinical features in these conditions, though they are usually more severe in Omenn syndrome.

Hair, including eyebrows and eyelashes, is usually lost as the rash evolves. Along with other clinical features of classical SCID, staphylococcal or *Pseudomonas* skin infections are particularly common and are often associated with elevated serum immunoglobulin (Ig) E levels with a marked eosinophilia.

Abnormalities in purine metabolism, due to ADA deficiency or purine nucleoside phosphorylase (PNP) deficiency result in the accumulation of toxic metabolites that damage lymphocytes. In ADA deficiency, the lymphocyte numbers may be normal at birth but fall rapidly. They also have bony changes like flaring of the anterior rib ends, blunting of the inferior angle of the scapula and pelvic dysplasia which are pathognomonic. PNP deficiency in addition presents with neurological features including a characteristic dysarthria and spastic diplegia.

Some patients may present with atypical form of SCID also called as *leaky SCID*. These patients have residual low number of T-cells ( $>300/\text{mm}^3$ ) and usually survive beyond 12 months of age. They present with severe infections which resolve only after

prolonged therapy. They may also present with autoimmune manifestations. They often result from hypomorphic mutations in genes normally associated with classical SCID retaining some protein function.

## WELL-DEFINED SYNDROMES WITH IMMUNODEFICIENCIES

Primary immunodeficiency disorders listed under this category have syndromic clinical manifestations along with the immunodeficiency. These syndromes are generally associated with variable degree of T-cell immunodeficiency. The common diseases listed under this category include Wiskott-Aldrich syndrome (WAS), DNA repair defects including ataxia-telangiectasia, DiGeorge anomaly (chromosome 22q11.2 deletion syndrome) and hyper-IgE syndromes (HIES).

### Wiskott-Aldrich Syndrome

This is a rare X-linked immunodeficiency disorder caused by mutation in Wiskott-Aldrich syndrome protein (WASp) gene. Classic WAS is characterized by thrombocytopenia with small platelets, eczema, recurrent infections, and increased risk for autoimmunity and malignancy. Hypomorphic mutations in WASp gene result in milder clinical form called X-linked thrombocytopenia.

Ataxia-telangiectasia is an AR disorder characterized by progressive neurologic impairment, variable immunodeficiency, impaired organ maturation, X-ray hypersensitivity, oculocutaneous telangiectasia, and a predisposition to malignancy.

### DiGeorge Syndrome

DiGeorge syndrome (DGS) is caused by deletions of the long arm of chromosome 22 at position q.11 and is very heterogeneous

with variable expression of the different features including the immunodeficiency ranging from normal T-cell numbers and function to complete DGS with a T-negative SCID-like picture. Classically it comprises of T-cell deficiency (due to thymic hypoplasia), hypoparathyroidism, cardiac malformations and facial abnormalities.

### Job Syndrome

These are HIES characterized by eczema in infancy, recurrent staphylococcal skin abscesses, recurrent pneumonia and serum IgE-levels. Both autosomal dominant (AD) and AR inheritance have been described. AD-HIES caused by heterozygous, dominant-negative mutations in *signal transducer and activator of transcription 3* (*STAT3*) is more common. In this form of HIES extra-immune manifestations occur, including skeletal abnormalities including a typical facial appearance, scoliosis, hyperextensibility, pathologic fractures, retained primary dentition, craniosynostosis, and retained primary teeth are common. The AR-HIES is characterized by recurrent viral and bacterial infections, extreme eosinophilia and elevated IgE without skeletal or dental abnormalities. The AR-HIES is caused by mutations in *dedicator of cytokinesis 8* (*DOCK8*) gene and rarely by a monogenetic defect in the cytoplasmic tyrosine kinase (*TYK2*) gene.

### PREDOMINANTLY ANTIBODY DEFICIENCIES

These are the most common type of immunodeficiencies, accounting for approximately 50% of all PIDs. More than 20 antibody-deficiency disorders are defined to date, the common ones include X-linked agammaglobulinemia (XLA; also known as Bruton agammaglobulinemia), common variable immunodeficiency (CVID), and selective IgA deficiency. They are characterized by an increased susceptibility to sinopulmonary infections with bacteria, particularly *Streptococcus pneumoniae* and *Haemophilus influenzae*. They are also prone to develop severe enteroviral infections. Other clinical manifestations such as diarrhea, fatigue and autoimmune manifestations (particularly autoimmune cytopenia and arthritis), are also seen in these patients.

Patients with CVID present commonly between 20 years and 40 years with similar symptoms. Other complications commonly seen in patients with CVID are chronic lung disease, systemic granulomatous disease, autoimmunity, lymphoid hyperplasia and infiltrative disease, gastrointestinal disease, and the development of hematolymphoid malignancies.

Milder antibody deficiencies especially *IgA deficiency* is a common immunological variant seen in 1:400–1:500 healthy individuals and more than 90% of the cases are asymptomatic. A subgroup of IgA-deficient patients develops recurrent sinopulmonary and gastrointestinal infections typical of antibody deficiency, yet invasive infections such as meningitis or sepsis generally do not occur. These patients must be investigated for associated antibody deficiency such as IgG2 subclass deficiency. IgA-deficient individuals are at an increased risk of developing autoimmune disease, particularly systemic lupus erythematosus and rheumatoid arthritis, and gastrointestinal disease such as inflammatory bowel disease and celiac disease. A higher prevalence of asthma and allergies has also been reported.

Other category under antibody deficiency is *hyper-IgM syndromes* (HIGM). These are a heterogeneous group of genetic disorders resulting from mutations in the genes directly or indirectly involved in B-cell signaling via CD40 and required for class switch recombination and somatic hypermutation. At least five distinct molecular defects, including mutations of the genes coding for the CD40 ligand (*CD40L*) and inhibitor of nuclear factor kappa-B kinase subunit gamma [IKK-gamma, NF-kappa-B essential

modulator (*NEMO*)] genes, both X-linked; and mutations of *CD40*, activation-induced cytidine deaminase (*AICDA*), and uracil-DNA glycosylase (*UNG*), associated with AR-HIGM syndromes. The common clinical manifestations include severe recurrent sinopulmonary infections intermittent or persistent neutropenia, autoimmune manifestations and malignancies. Since patients with CD40 and CD40L deficiency also have associated T-cell function defects, they are prone to infections with opportunistic organisms, such as *Pneumocystis carinii* pneumonia, chronic diarrhea due to *Cryptosporidium* infection leading to sclerosing cholangitis and are also categorized under CID.

### DISEASES OF IMMUNE DYSREGULATION

#### Hemophagocytic Lymphohistiocytosis

This is a rare life-threatening disease of immune regulation clinically characterized by prolonged fever, cytopenia and hepatosplenomegaly. Low or absent natural killer (NK) cell and CD8+ cytotoxic T-lymphocyte (CTL) cytotoxicity is one of the hallmarks of HLH and leads to prolonged and excessive activation of antigen presenting cells (macrophages, histiocytes) and CTLs resulting in multisystem inflammation. HLH may occur as a primary (genetic) condition due to mutations in genes important in the pathway of granule-mediated cytotoxicity or as a secondary condition where identical clinical findings may arise secondary to infectious, rheumatologic, malignant, or metabolic conditions. Several genetic causes predispose patients to HLH and these include familial hemophagocytic syndrome (FHL; in whom HLH is often the only presenting manifestation), immunodeficiencies with albinism and various primary immunodeficiencies which in particular diseases associated with impaired response to infection with Epstein Barr virus where HLH may occur though frequently along with other clinical manifestations. Defects in *PRF1* (FHL2), *UNC13D* (FHL3), *STX11* (FHL4) and *STXBP2* (FHL5) are known causes of FHL whereas the underlying molecular basis for FHL1. All these genes encode for proteins important for granule-mediated cytotoxicity. Central nervous system manifestations, like from seizures, altered mental status, cranial nerve palsies, blindness, unconsciousness, ataxia, etc., are also seen in patients with FHL especially FHL2.

#### Autoimmune Lymphoproliferative Syndrome

It is a disorder of lymphocyte homeostasis characterized by non-malignant lymphadenopathy, splenomegaly, autoimmunity mostly directed toward blood cells and increased risk of lymphoma. The median age of first presentation is 24 months of age, but with increasing awareness of the condition, adults with autoimmune complications are now being diagnosed more frequently. The most common mutation found in patients with autoimmune lymphoproliferative syndrome (ALPS), seen in around 70% of the patients, is the germ line heterozygous FAS mutation. Patients with somatic FAS mutations are now the second largest group of known genetic mutations in ALPS, followed by patients with caspase 10 (*CASP10*) and Fas-ligand (*FASLG*) mutations, respectively. All these mutations are inherited in an AD manner. However, cases with homozygous or compound heterozygous mutations have also been reported.

### PHAGOCYTE DEFECTS

Phagocytic leukocytes are an essential component of the innate immune system that has evolved to respond rapidly to the presence of invading bacteria, fungi, and parasites. Patients with defects in phagocytic function are predisposed to intracellular microorganisms and typically have an early dissemination of the infection.

## Chronic Granulomatous Disease

It is characterized by recurrent infections involving the skin and respiratory system. The majority of infections in chronic granulomatous disease (CGD), such as cellulitis, liver abscess, otitis media, pneumonias, pyoderma and periodontal disease, are caused by *Staphylococcus aureus*. Infection due to *Burkholderia cepacia*, *Serratia marcescens*, *Nocardia* species, and *Aspergillus* species are strongly of CGD.

## Myeloperoxidase Deficiency

It is necessary for intracellular killing of certain organisms by neutrophils and monocytes. A complete or partial deficiency of myeloperoxidase deficiency leads to mildly prolonged respiratory burst. Patients are often asymptomatic but susceptibility to *Candida* and *Staphylococcus* infections may be seen.

## Leukocyte Adhesion Deficiency

These syndromes result from failure of leukocyte to defend the host because of missing or dysfunctional surface adhesion molecules. Leukocyte adhesion deficiency (LAD) type I results from mutations in the *ITGB2* gene encoding for the  $\beta 2$  subunit (CD18) of  $\beta 2$ -integrin. It is the most common of the LAD syndromes presenting soon after birth with omphalitis and delayed separation of the cord (often beyond 21 days). High resting neutrophil count, recurrent bacterial infections of skin and mucosal surfaces which are necrotic rather than pustular with frequent dissemination and sepsis, poor wound healing and periodontal disease are common clinical manifestations. LAD type II syndrome results from a general defect in fucose metabolism, causing the absence of Sialyl-Lewis X and other fucosylated ligands for the selectins.

Affected patients present early in life, have recurrent bacterial infections with persistent leukocytosis, but do not have delayed separation of the umbilical cord. The infections are generally not life-threatening. These patients also have severe mental retardation, short stature, a distinctive facial appearance and the rare Bombay (hh) blood phenotype.

Leukocyte adhesion deficiency type III syndrome results from defects in *Kindlin-3* and *CalDAG-GEF1* genes. These patients have severe bleeding tendencies along with recurrent severe bacterial infections and leukocytosis. CD18 molecule is structurally intact in these patients and they show significant abnormalities in leukocyte and platelet integrin activation.

## Severe Congenital Neutropenia

The child has persistently low absolute neutrophil count (ANC) with elevated monocytes and eosinophils counts. Cyclic neutropenia patients present with drop in ANC every 3–4 weeks with fever, infections and mouth ulcers.

## Interferon- $\gamma$ /Interleukin-12 Pathway Defects

Patients with defects in interferon gamma receptor 1 (IFN- $\gamma$ R1), INF- $\gamma$ R2, interleukin 12 receptor beta 1 (IL-12R $\beta$ 1), IL-12 p40, and STAT1 have been identified through their extreme susceptibility to nontuberculous mycobacteria and BCG. These defects, all of which have been identified because of mycobacterial infection, have been grouped as Mendelian susceptibility to mycobacterial disease. They present early in life with disseminated severe infections, especially if they have received BCG vaccination, and have poor to absent granuloma formation. *Salmonella* and certain viral infections (herpes simplex virus, cytomegalovirus, parainfluenza, and respiratory syncytial virus) are also seen. Mortality in these children is high, and infections are severe and recurrent.

## DEFECTS OF INNATE IMMUNITY

Over the last few years, several defects in innate immunity have been discovered representing a new group of PIDs characterized by defects in pathogen recognition receptor signaling. The important four defects listed under this category include genes involved in nuclear factor kappa-light-chain-enhancer of activated B-cells (NF- $\kappa$ B) activation important in toll-like receptor (TLR) signaling: *NEMO*, nuclear factor of kappa light polypeptide gene enhancer in B-cells inhibitor, alpha (*I $\kappa$ B $\alpha$* ), interleukin-1 receptor-associated kinase 4 (*IRAK4*) and myeloid differentiation primary response gene 88 (*MyD88*). Patients with anhidrotic ectodermal dysplasia and immunodeficiency, which is caused by mutations in *NEMO* and *I $\kappa$ B $\alpha$* , have sparse hair, dry skin, and conical teeth and are at increased risk of severe infections caused by pyogenic bacteria and atypical mycobacteria.

Patients with *IRAK4* deficiency and *MyD88* deficiency are at increased risk of invasive bacterial infections, like meningitis, sepsis, arthritis, osteomyelitis and abscesses, due to *Streptococcus pneumoniae*, *Staphylococcus aureus* and *Pseudomonas aeruginosa* often in the absence of fever. These PIDs improve with age and patients often have no further invasive bacterial infections beyond their teenage years. These patients should receive conjugated and nonconjugated bacterial vaccines, antibiotic prophylaxis, and IgG replacement during the first decade of life.

## AUTOINFLAMMATORY DISORDERS

The disorders included under this category of PID are monogenic inherited disorders caused by dysregulation of innate immune system leading to aberrant inflammasome activation. To date, 12 monogenic AIDs have been identified; the common ones being: familial Mediterranean fever (FMF), mevalonate kinase deficiency (MKD), tumor necrosis factor receptor-associated periodic syndrome (TRAPS) and cryopyrin-associated periodic syndrome (CAPS). Clinical manifestations include recurrent inflammatory episodes with fever, and frequent involvement of the skin, serous membranes, eyes, joints, lymph nodes, gastrointestinal tract, and nervous system. Each of these syndromes varies in severity, duration, frequency and site of inflammatory signs and symptoms and their response to therapy with different anti-inflammatory and immunomodulatory therapy.

## Familial Mediterranean Fever

It is caused by loss-of-function mutations within the *MEFV* gene and is the most common AID. The classic phenotype is characterized by recurrent acute febrile episodes lasting 12–72 hours, sometimes triggered by stress, physical exercise. They may be associated with polyserositis especially peritonitis, arthritis, and erysipelas-like erythema usually localized on the surface of the legs between the hip and knee and/or on the top of the foot. In second phenotype of FMF, patients present as systemic amyloidosis as the sole manifestation of the disease.

## Mevalonate Kinase Deficiency

It is due to mutations in the *MVK* gene, encoding the second enzyme of mevalonate pathway. MKD usually starts in childhood within first 5 years of life with abrupt febrile flares that occur every 4–6 weeks and last about 3–7 days on average, with headache, mouth ulcers, abdominal pain, vomiting, and/or diarrhea with joint involvement in the form of arthralgia and/or arthritis, especially affecting large joints, a nonspecific maculopapular rash. The episodes are sometimes induced by vaccinations or viral infections. Attacks are generally more frequent during childhood and adolescence, but the disease may persist into adulthood in more than half of patients.

## Tumor Necrosis Factor Receptor-associated Periodic Syndrome

It is caused by mutation in *TNFRSF1A* gene. This is the most common dominant form of AID in Europe, historically known as *familial Hibernian fever*. Patients complain of inflammatory attacks of extremely variable duration and intensity (from 1–2 days to 3–4 weeks), accompanied often by sterile peritonitis with abdominal pain, diarrhea/constipation, nausea, and vomiting. Mono or bilateral periorbital edema is a characteristic feature of the disease, often associated with conjunctivitis and periorbital pain. Secondary amyloidosis is seen in 25% of the patients.

## Cryopyrin-associated Periodic Syndromes

These are a group of AID transmitted by AD inheritance caused by mutations in the *NLRP3* gene encoding for cryopyrin, a crucial inflammasome protein that directly activates IL-1 $\beta$ . There are three known forms of CAPS. The least severe is *familial cold autoinflammatory syndrome* which usually appears in early childhood and is characterized by brief recurrent inflammatory episodes triggered by exposure to cold or sudden change in temperature. *Muckle-Wells syndrome* is the clinical phenotype of medium severity with recurrent or chronic inflammatory symptoms often associated with episcleritis, neurosensorial deafness, and secondary amyloidosis (in up to 25% of cases). Finally, *chronic infantile neurological cutaneous articular syndrome* also known as neonatal-onset multisystem inflammatory disease, the most severe form presents with additional clinical manifestations like hypertrophic arthropathy involving both epiphyses of long bones and kneecaps, uveitis, papilledema, optic nerve atrophy leading to blindness, elevated intracranial pressure, deafness, and growth retardation.

## COMPLEMENT DEFICIENCIES

The complement system is a key component of innate immunity. More than 45 genes encoding the proteins of complement components or their isotypes and subunits, receptors, and regulators have been discovered. Deficiencies of all the soluble components and many membrane receptors and regulatory proteins have been described. Most of them are AR, although deficiency of C1q esterase is AD and that of properdin is X-linked. Genetic deficiency of any early component of the classical pathway (C1q, C1r/s, C2, C4, and C3) is associated with autoimmune diseases due to the failure of clearance of immune complexes and apoptotic materials. They also have impairment of humoral response and varying degree of susceptibility to bacterial infections especially encapsulated bacteria like *Streptococcus pneumoniae*, *Streptococcus pyogenes* and *H. influenzae*. Deficiencies of mannan-binding lectin and the early components of the alternative (factor D, properdin) and terminal pathways (from C3 onward components: C5, C6, C7, C8, C9) predominantly present with increase susceptibility to bacterial infections especially *Neisseria meningitidis*. Although blood-borne systemic infections, such as bacteremia and meningitis, are the most common manifestations, localized infections, like sinusitis, otitis and pneumonia, may also be seen in the complement deficient individuals. Also the prevalence of complement deficiencies is significantly higher in individuals with systemic meningococcal infections especially patients with recurrent disease (40%) and with positive family history (10%) or an unusual serotype of the meningococcus (20–50%).

## PHENOCOPIES OF PID

In the new updated PID classification of 2013, a new category, *phenocopies of primary immunodeficiencies*, has been added to the existing classification. This includes disorders which manifest

as inherited deficiencies of the immune system, but are not due to germ line mutations. Acquired mechanisms, such as somatic mutations and autoantibodies to cytokines or other immunologic factors, are implicated in their pathogenesis. The disorders included in this broad category include:

- Disorders with somatic mutations in the Kirsten rat sarcoma viral oncogene homolog (*KRAS*) and neuroblastoma RAS viral (v-ras) oncogene homolog (*NRAS*) genes mimicking a ALPS like phenotype
- Disorders with autoantibodies to cytokines and other immunological factors such as IL-17, IL-22, IFN- $\gamma$ , IL-6, granulocyte-macrophage colony-stimulating factor and C1 inhibitor.

## LABORATORY APPROACH

The investigations are largely guided by the clinical presentation of the patient, the suspected immune defect and the results of initial laboratory evaluation. The laboratory approach toward diagnosis of patients with PID can be broadly divided into two: approach for patients with recurrent infections and diagnosis of other PID either with syndromic manifestation, AIDs and disorders of immune dysregulation. Patients in the second category require totally different set of investigations and many of the diseases in this category have their individual diagnostic criteria. Discussing them individually is beyond the scope of this chapter and hence we will focus on evaluation of patients with recurrent infections.

For evaluation of patients with recurrent infections, the first and the most important step is to look at the complete blood count carefully. Look for ANC, absolute lymphocyte count (ALC), eosinophil counts, monocytes and platelet count carefully. Low ALC suggests combined immunodeficiency (CID) while low ANC suggests severe congenital neutropenia (SCN) or autoimmune neutropenia. Low platelet counts with low mean platelet volume suggest WAS. Persistently elevated ANC suggests LAD type I while high ALC is seen in patients with ALPS. Eosinophilia is often associated with HIES and Omenn syndrome. The most useful first-line immunological investigations include lymphocyte subset analysis, serum Ig levels and nitroblue tetrazolium test (NBT).

The panel of antibodies used lymphocyte subset analysis should include CD3, CD4, CD8, CD56/16, CD19 and human leukocyte antigen-DR (HLA-DR). It is aimed at measuring the absolute and relative number of:

1. B-cells (CD19+)
2. T-cells (CD3+)
3. T-helper cells (Th, CD3+/CD4+)
4. T-cytotoxic cells (Tc, CD3+/CD8+)
5. Natural killer cells (CD3-/CD56+/CD16+)
6. Activated T-cells (CD3+/HLA-DR+).

The total lymphocyte numbers and T-lymphocyte subsets are age dependent, being markedly increased in newborns and young infants and decreasing with age. In infants below 4 months of age, a CD4 count of less than 1000/mm<sup>3</sup> is generally associated with impaired cellular immunity, whereas the corresponding value is less than 500/mm<sup>3</sup> in children over 2 years of age and in adults. Immunosuppressive therapies like steroids also significantly alter the values of T- and B-cell subsets and should be interpreted carefully.

The results of these initial tests usually give an important clue to the underlying immune defect. Patients with low T-cell counts are likely to have CID. Patients with low or absent B-cell, low Ig levels and normal T-cell come under the category of predominantly antibody deficiency. Patients with abnormal neutrophil count or abnormal neutrophil function suggest defects in the phagocytic system. Large number of flow cytometry-based assays which measure cell number, cell function or expression of particular antigen/molecule on the cells help in diagnosis of individual disorders.

## Evaluation of Suspected CID

Lymphocyte subset analysis is abnormal in most cases of SCID and in many cases of CID. SCID is categorized broadly as T+ SCID and T- SCID depending on presence or absence of the T-cells. There are many genetic defects which can lead to T- SCID phenotype. The B-cells and NK cells count in these patients give an important clue to the underlying molecular defects (**Flow chart 1**). However, there is significant overlap between these categories and hence specialized tests, like CD132 and CD127 expression, functional studies, like pSTAT5 activation in lymphocytes after IL-2 stimulation, estimation of enzymes, like ADA and PNP in red blood cells, radiation sensitivity test, etc., are required for specific diagnosis.

Patients with normal T-cell numbers can still have CID. This is usually seen with patients with Omenn syndrome, major histocompatibility complex (MHC) class I or MHC class II deficiency, zeta-chain-associated protein kinase 70 (ZAP-70) deficiency, etc. These patients can be evaluated by doing T-cell proliferation assays (for evaluation of T-cell function), expression of HLA-DR on T and B-cells (for MHC class II expression) and T-cell receptor V $\beta$  repertoire analysis (for assessment of diversity of immune response).

## Evaluation of Patients with B-cell Defect

Patients with suspected B-cell defects require estimation of B-cell numbers (CD19, CD20 and CD79a), serum Ig levels (IgG, IgA, IgM, IgE and IgG subclasses). Patients with absent B-cells and markedly reduced Ig are suggestive of agammaglobulinemia which can be XLA or AR agammaglobulinemia. Patients with XLA will have absent or reduced expression of protein Bruton tyrosine

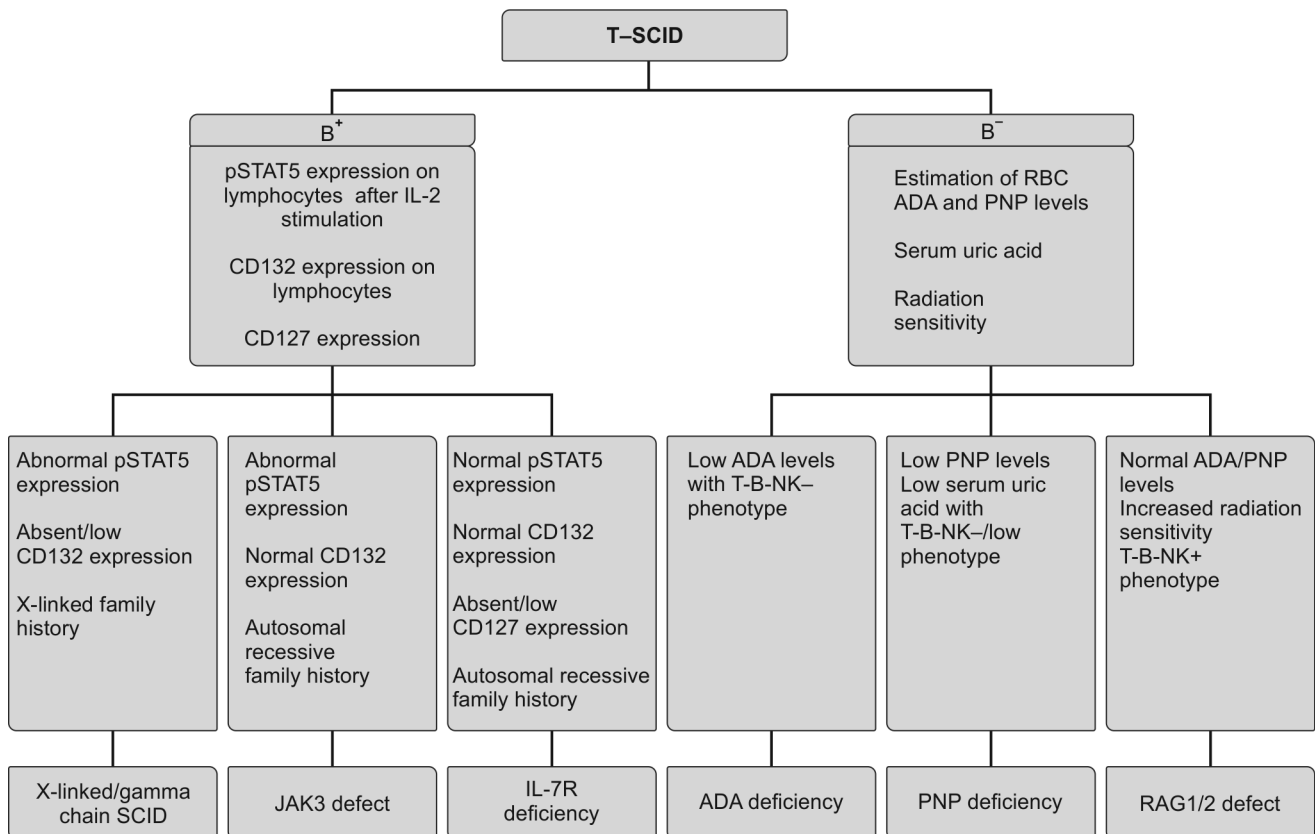

kinase with carrier mothers showing mosaic pattern. Patients with reduced Ig with normal to low B-cells with abnormal specific antibody responses suggest CVID. Patients with HIGM have markedly low IgG and IgA with normal to elevated IgM levels. They can be further evaluated by studying expression of CD40 and CD40L (CD154) expression on B-cells and T-cells, respectively. Patients with X-linked HIGM will have abnormal CD154 expression on T-cells after stimulation and carrier mothers will show mosaic pattern.

Patients with strong clinical suspicion of antibody deficiency with normal or only modestly reduced Ig levels should be evaluated for specific antibody titers (usually IgG) in response to vaccine antigens and IgG subclass levels. This approach involves immunizing a patient with protein antigens (e.g., tetanus toxoid) and polysaccharide antigens (e.g., pneumococcus) and assessing pre- and postimmunization antibody levels. In many PIDs, antibody responses to these antigens are diminished or even absent.

## Evaluation of Patients with Phagocytic Defects

In a patient with suspected phagocytic defect one must look at the ANC. A patient with low ANC with early neonatal presentation is suggestive of SCN. Characteristically, there is marked monocytosis with levels often 2–4 times that of normal. There may be associated anemia and mild thrombocytosis attributable to chronic inflammation. Bone marrow examination shows the presence of early precursor cells but very few mature cells beyond the promyelocyte stage or *promyelocyte arrest*. Patients with cyclic neutropenia have oscillations of neutrophil count with a periodicity of around 21 days. At the nadir, neutrophil counts are

**Flow chart 1** Evaluation of patients with common T-SCID

**Abbreviations:** SCID, severe combined immunodeficiency; pSTAT5, phosphorylated *signal transducer and activator of transcription 5*; IL, interleukin; JAK3, Janus kinase 3; ADA, adenosine deaminase; PNP, purine nucleoside phosphorylase; RAG, recombination activating gene; CD, cluster of differentiation; RBC, red blood cell; T-B-NK-, T-cell negative, B-cell negative and natural killer cell negative; T-B-NK+, T-cell negative, B-cell negative and natural killer cell positive.

generally less than  $0.2 \times 10^9/L$  for 3–5 days, after which they rise rapidly to levels near the lower limit of normal, about  $2 \times 10^9/L$ . Both SCN and cyclic neutropenia commonly result from mutations in neutrophil elastase gene (*ELA-2*).

Patients with suspected CGD have normal or elevated ANC and can be diagnosed by NBT and dihydrorhodamine test. These tests can also detect carrier mothers in X-linked CGD. Final confirmation of underlying defect can be done by studying the intracellular expression of gp91 for X-CGD and p22, p67 or p47 for AR-CGD followed by molecular analysis of the affected gene. Patients with LAD type I can be easily diagnosed by flow cytometric analysis of CD18, CD11a, CD11b and CD11c expression on peripheral blood leukocytes.

### Evaluation of Patients with Disorders of Innate Immunity

Standard immunological laboratory tests, such as blood cell and differential cell counts (platelet counts, ALC, neutrophil and eosinophil counts), lymphocyte subsets and CH50 (total complement activity) determinations will be normal in most patients suffering from a defect of the TLR/NF- $\kappa$ B pathway, whereas Ig levels are variable in MyD88, IRAK4 and NEMO deficiencies. The diagnosis of defects of the TLR/NF- $\kappa$ B pathway is, therefore, challenging and requires specific laboratory evaluations of TLR function. Enzyme-linked immunosorbent assays (ELISAs) or related assays are used to measure the ex vivo production of a number of cytokines [tumor necrosis factor alpha (TNF $\alpha$ ), IL-6, IL-10, IL-12/IFN- $\gamma$  and type I IFNs] by whole blood or peripheral blood mononuclear cells after stimulation with different TLR ligands. Rapid flow cytometry methods for detecting intracellular TNF $\alpha$  production or shedding of CD62L after stimulation with TLR ligands are useful screening tools for functional evaluation of TLR/NF- $\kappa$ B pathway. Depending on the results of these assays further genetic evaluation can be performed.

### Evaluation of Patients with Complement Deficiency

Initial evaluation is done with the CH50 (which tests the classical and final lytic components except C9) and AH50 (which tests alternative and final lytic pathways) assays. It is advisable that the assays be performed when the patient has completely

recovered from immune complex disease or infection. Both the tests require (X the) blood to be taken atraumatically and serum be separated within 1 hour and stored at  $-70^\circ\text{C}$ . If either of these screening tests identifies failure of a complement pathway on two occasions, the specific component defect should be determined.

### IN A NUTSHELL

1. Diagnosis of specific PID from a large spectrum of disorders requires expertise in clinical and laboratory evaluation.
2. Suspecting PID based on various clinical manifestations is the most important step in diagnosis of PID.
3. Wide array of assays are available for evaluation of immune system which help immensely in the diagnosis of PIDs.
4. Knowledge of clinical presentation of these disorders, correct interpretation of initial results of immunophenotyping of lymphocytes is essential for choosing the appropriate test for specific diagnosis.
5. There is very little data available from India on PID. Being a country with the second largest population in the world, we are likely to have large number of patients with PIDs.
6. Recognizing a suspicious case of PID at a regional hospital level is important to ensure timely referral to a specialized center for diagnosis and treatment for these patients.

## Chapter 4.4

# Therapy for Primary Immunodeficiency Disorders

Revathi Raj, Surjit Singh

The field of primary immunodeficiency disorders (PIDs) is still at its infancy in India. Each year, a significant number of infant and early childhood deaths could be due to an unrecognized immunodeficiency disorder. Exciting therapeutic developments have occurred in the care of these children including availability of intravenous immunoglobulins, optimal supportive care with antibiotics, hematopoietic stem cell transplantation and gene therapy. Early diagnosis and prompt referral to a center of excellence goes a long way in ensuring a high rate of cure for these children who pose fresh and interesting challenge at every stage of management.

## MANAGEMENT OF ANTIBODY DEFICIENCIES

Intravenous immunoglobulins (IVIG) were first introduced in 1952 to treat children with immunodeficiency. IVIG contains pooled immunoglobulin G (IgG) from over a thousand plasma donors and it is a sorbitol based formulation to minimize reactions during administration. IVIG given at a dose of 400 mg/kg every 28 days intravenously has made long-term survival a reality in patients with X-linked agammaglobulinemia. Other indications include children with severe combined immunodeficiency as a bridge to hematopoietic stem cell transplantation, common variable immunodeficiency, hyper IgM syndrome and Wiskott-Aldrich syndrome. Details of IVIG therapy are provided in a separate chapter in this *Section*.

## SUPPORTIVE THERAPY

### Prophylactic Antibiotics

Antibiotic prophylaxis is the standard of care in several PID. Pneumocystis pneumonia (PCP) is the hallmark infection in T-cell deficiency. This can be prevented by using co-trimoxazole at 5 mg/kg/day of trimethoprim 3 days a week. Fungal infections, particularly *Candida* causing oral thrush can be prevented by the use of fluconazole at 6 mg/kg/day. Children with neutrophil dysfunction like chronic granulomatous disease and hyper IgE syndrome can be managed with prophylactic co-trimoxazole to prevent staphylococcal infections and itraconazole at 5 mg/kg/day on a daily basis to prevent *Aspergillus* infection. Children with complement deficiency who are at risk of infection from diplococci can be managed with penicillin prophylaxis at Penicillin G at 400 mg or 400,000 units for above 5-year-old children twice a day and 200 mg or 200,000 units twice a day for children below 5 years of age.

### Diet in Primary Immunodeficiency Disorders

Children with PID need to be taken care of in a safe and clean environment. A low bacterial diet helps prevent diarrhea and sepsis. The use of tap water for mouth care must be avoided to prevent the risk of acquiring chronic *Cryptosporidium* diarrhea. Exposure to woodwork or building construction can result in *Aspergillus pneumoniae*. Breastmilk is the optimal diet for infants. Hypoallergenic formulae like rice or soya based diet will help prevent loose stools and failure to thrive. Children with neutrophil dysfunction are asked to consume freshly prepared home cooked foods and to avoid salads and fresh fruits, other than those in

which the skin can be peeled and consumed in a fresh manner. Soft cheese can result in listeriosis and is to be avoided. Pasteurized milk and yogurt are safe for consumption. Canned foods are best to be avoided.

## Treatment of Infections

Children with PID are present with infections and need to be treated in an aggressive manner with specialists input from the *Infectious Diseases* department. Bacterial infections are most common and the source of infection is usually the child's own body. Streptococci from the throat, staphylococci from the nostrils and skin, gram-negative bacteria from the gastrointestinal tract are all commonly seen and need to be treated with appropriate antibiotics based on local antibiotic policy. Complement deficiency children are prone to infections with opsonization defect and can be treated with penicillin or cephalosporins after appropriate cultures when they present with a fever. Atypical bacterial infections like *Burkholderia* or *Stenotrophomonas* are seen in children with chronic granulomatous disease. If the child does not respond to upfront broad spectrum antibiotics, early imaging with CT chest and bronchoscopy and culture will help guide further therapy. A baby with severe combined immune deficiency presenting with respiratory distress could be harboring cytomegalovirus, pneumocystis or disseminated BCG infection. Early intervention with ganciclovir, high dose cotrimoxazole or antituberculous drugs will help stabilize the child for transplantation.

## DEFINITIVE THERAPY

Hematopoietic stem cell transplantation is the only curative option for children with immune deficiency. In 1968, hematopoietic stem cell transplantation (HSCT) was first performed for a child with severe combined immunodeficiency (SCID). At the same time, another child with Wiskott-Aldrich syndrome (WAS) transplanted from a matched sibling. Since then, HSCT techniques have advanced due to high resolution human leukocyte antigen (HLA) typing, the availability of alternative donors like umbilical cord blood, less toxic chemotherapeutic conditioning and graft-versus host disease (GVHD) prophylaxis. Supportive care has improved with newer antifungal agents, rapid detection of viral infections using PCR-based assays enabling pre-emptive antiviral treatment before the onset of organ damage. Increased awareness of primary immunodeficiency (PID) amongst general pediatricians has led to earlier diagnosis and referral to specialist centers and better outcomes.

### Hematopoietic Stem Cell Transplantation

Hematopoietic stem cell transplantation (HSCT) aims to give stable donor stem cell engraftment to help regain full immune system. The overall survival has increased to 80% for babies with a genotypical donor and nearly 70% for those given matched unrelated donor (URD) HSCT. It is important to have precise molecular diagnosis as the prognosis can then be accurately assessed. For instance, the outcome following HSCT for patients with B negative forms of SCID such as RAG deficiency is less good than for those with B positive forms and those with Artemis deficiency have a worse prognosis than those with RAG deficiency because of the associated cellular radiosensitivity.

**Donor choice** The first step involved in HSCT is to identify a HLA matched donor for donating stem cells. The best HLA matched donor is a sibling and so any siblings of the patient should be tissue typed along with parents and if possible the extended family. If there are no matched family donors, search in the National and International unrelated donor registries is done as a high priority to obtain a donor at the earliest. There are currently 19 million adult

and over 500,000 cord blood donors that can be accessed through the Bone Marrow Donors Worldwide registry.

**Stem cell source** Bone marrow is the choice for source of stem cells and is harvested under general anesthesia from the posterior iliac crests. The option of donating peripheral blood stem cells (PBSC) rather than bone marrow is more appealing for adult donors as this avoids a general anesthesia. Umbilical cord blood stem cell transplantation (UCSCT) is a readily available stem cell source when a matched sibling donor is unavailable. The advantages of UCSCT include quick access to the cord blood unit and ease of arranging date of transplant, absence of risk to donor, lower risk of latent viral transmission and graft versus host disease (GvHD) and finally a higher chance of matching rare HLA haplotypes. Half matched parent or sibling transplantation is called haploidentical HSCT and is offered if there are no matched donors in unrelated or cord blood registries. This is used as a last choice as immune reconstitution is delayed for over 6 months to a year exposing the children to infections over prolonged periods of time.

**Assessment of donor and recipient** The donor and recipient need to go through mandatory tests including those for HIV, HBsAg, anti-hepatitis C antibody, VDRL, cytomegalovirus, herpes simplex virus and blood group.

### Preparation of Patient

Once the decision to transplant has been made and a donor selected each organ system should be assessed so that any infection is treated prior to transplant. Many children with PID fail to thrive and are malnourished and it is important to improve their nutritional status prior to transplant. This may be by high calorie enteral feeding via nasogastric tube or parenteral nutrition through a central venous catheter.

**Conditioning** Conditioning aims to create space in the recipient marrow niche to enable donor stem cells to engraft more easily. Newer drug combinations like treosulfan and fludarabine are superior when compared to busulfan and cyclophosphamide and have helped to reduce transplant related toxicity and ensure excellent survival. Infants with T negative, B positive, NK negative SCID can have stem cell infusion with no conditioning as they rarely reject a new graft.

**Stem cell infusion** The stem cells harvested from the donor are transfused into the recipient into a central vein. In haploidentical transplantation, T-lymphocytes are depleted from the stem cells to remove of alloreactive lymphocytes enabling transplantation across HLA barriers. The most commonly used method, the Miltenyi CliniMACS system, uses an organic iron bead attached to an anti-CD34 antibody to isolate purified CD34+ HSCs from the other cells by passing the HSC source through a magnetic column and the purified CD34+ HSC fraction is infused into the patient.

**Supportive care** Infections, veno-occlusive disease, mucositis, graft versus host disease and graft rejection are the main complications seen after infusion of stem cells.

**Post-transplantation immune-reconstitution** Full immune-reconstitution can take up to 2 years post-transplant. The children need to remain on immunoglobulin replacement for around 6 months post-transplant or until evidence of immunoglobulin production as evidenced by an increase in IgM production. Vaccines are then introduced and antibiotic prophylaxis can be discontinued. Children should be monitored for endocrine dysfunction— particularly thyroid dysfunction, growth and late side effects.

## GENE THERAPY

Children with SCID were the first to be treated with novel methods like gene therapy where the missing gene is introduced into the cells by a viral vector system. Gene therapy is now used for SCID, Wiskott-Aldrich syndrome and chronic granulomatous disease.

## ENZYME REPLACEMENT

Children with SCID due to deficiency of the enzyme adenosine deaminase have benefitted from replacement of the enzyme. Long-term results for drug safety over a decade are now available. The disadvantage is the huge costs involved and commitment to lifelong infusions.

### IN A NUTSHELL

1. Matched sibling donor transplantation for primary immunodeficiency disorders offers over 80% chance of cure.
2. Early referral for hematopoietic stem cell transplantation (HSCT) before the onset of organ damage ensures optimal outcome.
3. Novel stem cell sources such as T-cell depleted haploidentical stem cells and cord blood stem cells have ensured that every child is offered a chance of cure.
4. Enzyme therapy and gene therapy help alleviate symptoms in some forms of PID.
5. Intravenous immunoglobulin use is the backbone of care in children with primary immunodeficiency.

## Chapter 4.5

# Intravenous Immunoglobulin

Sujoy Khan, Surjit Singh

Intravenous immunoglobulin (IVIG) is prepared from pooled human plasma of between 3,000 and 15,000 healthy donors and contains predominantly of polyvalent immunoglobulin G (IgG). The large number of donors in the pool allows a broad range of anti-infective and immunomodulatory activities and is therefore the treatment of choice for primary immunodeficiency diseases like antibody deficiency and several autoimmune conditions. IVIG was first demonstrated to be useful in immune (idiopathic) thrombocytopenic purpura in childhood in the early 1980s and since then, use of Ig has been found to be beneficial in several different areas in pediatric practice (Table 1).

Immunoglobulins are comprised within the gamma portion of plasma proteins (Fig. 1) generated by an individual's immune system and are composed of five different isotypes (IgG, IgA, IgM, IgD and IgE), of which IgG is the most abundant. Polyvalent human immunoglobulins are produced along with several other therapeutic plasma proteins (such as coagulation factors, albumin) from the pooled plasma through a process called fractionation. The plasma can be collected either through the quicker process of blood donation (average 30 minutes, 5–6 donations per year) or through plasmapheresis (donation takes 1–1.5 hours, 20 donations possible per year). Only specialized plasma collection centers can deal with the latter as they require large equipment and freezer capacity and need to fulfill specific criteria including a small compensation amount to the donor for time spent in donations. Individual donor units are screened for hepatitis B and C viruses and HIV. After the cryoprecipitate is removed, cold ethanol (Cohn) fractionation of the resultant precipitate is used in several steps, a process developed in the 1940s by Professor Edwin J Cohn. The product is then treated by solvent-detergent (SD) or other chemicals, by pasteurization or nanofiltration for viral inactivation or virus removal, with some manufacturers adding a prion filter to further reduce the chances of transmission of prion disease. The final sterile product has a wide spectrum of antibacterial and antiviral including possibly antiparasitic antibodies.

Human Ig contains more than 95% IgG with minimal quantities of IgA and IgM but the latter globulin fractions do not have a therapeutic significance because of their short half-life (<7 days). The IgG portion in all preparations has half-life between 18 days and 25 days, with physiologically similar IgG subclasses, have minimal anticomplementary activity, diverse antibacterial and antiviral activity, and negative for hepatitis B surface antigen, hepatitis C virus, and HIV.

## MECHANISMS OF ACTION

The human body uses a distinct mechanism of the physiological role of IgG that is dependent on both the Ig dose (such as replacement 400–600 mg/kg or high-dose 1–2 g/kg body weight) and the pathological process under consideration.

## Effects due to the Antibody Binding Portion of Immunoglobulin G

Even though commercially available IVIG preparations are known to have significant batch-to-batch variations of pathogen-specific antibodies, the large donor pool allows the neutralization of a wide range of pathogens including superantigens. In vitro studies have shown that IVIG has significant inhibitory effects on mitogen induced T-cell proliferation, but more when the IgG is intact with both complement binding Fc and F(ab')<sub>2</sub> portions. Laboratory studies have shown that IVIG has the ability to suppress the proliferation of antigen-specific T-cells without inducing apoptosis, a mechanism thought to be important in ameliorating antigen-dependent and antigen-independent inflammatory processes in autoimmune conditions. IVIG contains Fas-blocking antibodies reducing keratinocyte death in toxic epidermal necrolysis.

As the IgG in IVIG is derived from a donor pool, it was thought to be an *end product*, but study into the in vitro differentiation of dendritic cells with IVIG from patients with X-linked agammaglobulinemia (XLA) who lack B-cells and antibodies proved that it contains germ line encoded natural IgG antibodies (i.e., can be generated in the absence of infection or vaccination). Dendritic cell differentiation is impaired in XLA, and the defect was reversed by natural antibodies (in the IVIG) reactive with CD40. Furthermore, anti-idiotypic antibodies in IVIG possibly play a role in the treatment of immune thrombocytopenic purpura (ITP).

**Table 1** Uses of intravenous immunoglobulin in pediatric practice

Immunology	Hematology	Dermatology	Neurology	Rheumatology and others
Primary antibody deficiency (XLA, CVID, HIGM, WAS and others)	Immune thrombocytopenic purpura	Kawasaki disease	Guillain-Barré syndrome	Systemic lupus erythematosus
Severe combined immunodeficiency	Neonatal allo (iso) immune thrombocytopenia	Blistering disorders	Childhood myasthenia gravis (myasthenic crisis, or before thymectomy)	Systemic onset JRA
Post-HSCT	Postbone marrow transplant	DRESS syndrome		Pediatric HIV infection
	Autoimmune neutropenia			Premature neonates
	Autoimmune hemolytic anemia			Autoimmune uveitis
	Parvovirus-B19 associated aplasia			Burn patients
	Hemophagocytic lymphohistiocytosis			

Abbreviations: XLA, X-linked agammaglobulinemia; CVID, common variable immunodeficiency; HIGM, hyper-IgM syndrome; HSCT, hematopoietic stem cell transplantation; JRA, juvenile rheumatoid arthritis; HIV, human immunodeficiency virus; WAS, Wiskott-Aldrich syndrome.

**Figure 1** Electropherogram showing peaks of different plasma proteins including immunoglobulins (gamma portion, extreme right)

### Effects of Intravenous Immunoglobulin due to Binding to Fc Receptor

The binding of IgG Fc to the only inhibitory Fc receptor (FcγRIIb) and the activating (FcγRI and FcγRIII) Fc receptors exerts several effects. IVIG competitively binds to FcR on macrophages in the liver and spleen and this is the postulated mechanism behind clearance of cells in autoimmune cytopenia. Binding of IVIG to the inhibitory receptor FcγRIIb prevents phagocytosis. Ig therapy induces the proinflammatory cytokines interferon gamma (IFN-γ), interleukin-6 (IL-6) and IL-1Rα (may be up to 1,000 fold), while IL-1 and IL-2 are downregulated by IVIG. However, this is always not the case as evident in children with ITP who go into remission; IVIG therapy induces the anti-inflammatory T helper cell (Th2) cytokines. This may be due to: (1) differential control of FcR expression, such as cross-linking of FcRI on macrophages, that leads to (2) downregulation of IL-12 production and hence of Th1 cytokines.

### Effects of Intravenous Immunoglobulin due to Complement-Fc Binding

Intravenous immunoglobulin modulates complement activity, as seen in the clinical response to IVIG in patients with dermatomyositis, a complement-mediated microangiopathy. IVIG also activates the classical and alternate pathway, as antibodies do; however, high-dose IVIG is able to *breakdown* immune complexes thus preventing further complement-mediated amplification.

### Antibodies against Soluble and Membrane Molecules

Intravenous immunoglobulin preparations contain cytokines, cytokine inhibitors, soluble CD4 including major histocompatibility complex class II molecules. The various stabilizing agents used such as the sugars maltose and sucrose can also exert an effect that can inhibit in vitro mitogen responses [such as phytohemagglutinin (PHA)—and to a lesser extent, phorbol myristate acetate (PMA)-induced proliferative responses] but the clinical effect appears minimal.

### Intravenous Immunoglobulin Expands Regulatory T-cells Population

A special subpopulation of T-cells that suppress activation of the immune system and maintain tolerance to self-antigens has been extensively characterized. The thymus produces these *self-check* T-cells that can be CD8+ or CD4+CD25+Foxp3+ regulatory

T-cells (also referred to as the *naturally occurring* Tregs). Treg cells produce the immunosuppressive cytokines transforming growth factor beta (TGF-β) and IL-10, which provides an explanation of their function in preventing autoimmunity. Studies have shown that IVIG modulates various myeloid and lymphoid cell populations. High-dose IVIG in autoimmune disease induces a down-modulation of monocyte-derived dendritic cells and expression of co-stimulatory molecules, which in turn prevents autoreactive T-cell proliferation. Experiments have shown that prophylactic infusion of IVIG prevented the development of experimental autoimmune encephalomyelitis, an accepted animal model for multiple sclerosis (MS). The protection was associated with peripheral increase in Tregs' number and function. Other investigators have also shown that IVIG inhibited expression of adhesion molecules on dendritic cells that prevented relapses of MS.

### Differential Effects of Intravenous Immunoglobulin due to IgG Glycosylation Status

G Bock and S Harnett in their book "*Carbohydrate recognition in cellular function*" (John Wiley and Sons, 1989) had commented that "...while the functions of DNA and proteins are generally known... it is much less clear what carbohydrates do". This holds true in most aspects of medicine even today. The major serum Ig, IgG, is a glycoprotein and the constant domains of the heavy chain (Fc portion) undergo modification at a single site (Asn297) by covalent bonds with carbohydrates (N-linked glycosylation). Over 30 different glycans (fucose, galactose, sialic acid) have been detected at this site (**Fig. 2**). Glycosylation of the Fc portion of IgG is considered to be essential in the maintenance of an open conformation of the heavy chains to engage specific FcγR. Disruption of glycosylation of Fc region disrupts several effector functions and results in increased agalactosylated IgG levels (G0 glycoform), which enhance immune complex formation in rheumatoid arthritis and are associated with various autoimmune diseases. The sialylation status of IgG in IVIG remains unknown in commercial Ig preparations, and is theoretically plausible that a low fraction is fully glycosylated that can engage inhibitory FcR, given the requirement of high doses to treat autoimmune diseases like cytopenia (ITP, autoimmune neutropenia).

## MAJOR CLINICAL INDICATIONS OF INTRAVENOUS IMMUNOGLOBULIN

### Primary Immunodeficiency Disorders

The advent of IVIG (intravenous) in the 1970s paved the way to the first major randomized trials of Ig replacement therapy and showed that IVIG was not only as good but perhaps superior to intramuscular immunoglobulin (IMIG) in reducing infection frequency in primary antibody disorders. The pros were quite obvious: use of relatively small doses of IVIG at 0.15 g/kg were effective; significantly less painful than IMIG. Clinical studies by various groups established the concept of *trough IgG* and that maintenance of a trough serum IgG level in excess of 5 g/L using doses of 0.6 g/kg (600 mg/kg) resulted in (1) greater reduction in infections; (2) significant improvement in spirometric indices compared to those patients who received 0.2 g/kg and (3) significantly better quality of life indices.

It is now universally accepted amongst clinical immunologists that trough IgG levels should definitely be maintained within the age matched normal reference range for patients with antibody deficiency with individual patients benefiting from higher through levels (sometimes > 8 g/L). Most centers use 0.4–0.6 g/kg (400–600 mg/kg) of IVIG every 21–28 days and aim for a trough

**Figure 2** The different sugar moieties on the IgG molecule

IgG level more than 5 g/L. Several studies have documented decrease in incidence of pneumonias in children with XLA and common variable immunodeficiency once IVIG is commenced. IVIG therapy, however, does not lead to reversal of lung pathology such as bronchiectasis despite persistent trough IgG more than 5 g/L, suggesting that disturbance of the immune system needs to be checked in certain primary or acquired antibody disorders than simply replacing the *missing* IgG.

### Immune Thrombocytopenic Purpura

Immune thrombocytopenia is characterized by thrombocytopenia, increased bone marrow megakaryocytes and reduced platelet survival. The first-line of treatment for children with ITP is a short course of corticosteroids failing which a single dose of IVIG (0.8–1.0 g/kg) should be used. In some patients, IVIG can be used instead of corticosteroids (Grade IV evidence). There is no evidence to support using corticosteroids for longer courses given the multiple complications associated with them. Anti-D may be considered for first-line therapy in Rh+ nonsplenectomized children with recognition of the risks such as active bleeding or in those with evidence of autoimmune hemolysis, where anti-D is contraindicated.

### Kawasaki Disease

Intravenous immunoglobulin together with high-dose aspirin is an established first-line therapy for acute Kawasaki disease (KD). The most important therapeutic benefit of high-dose IVIG (2 g/kg) lies in the prevention of development of coronary artery aneurysms, from 20% to 25% in untreated KD to less than 5% after IVIG therapy. **Table 2** provides a scoring system to judge efficacy of IVIG given during the acute phase.

### Bone Marrow Transplantation

Intravenous immunoglobulin has been shown to be effective in young bone marrow transplant patients (age > 20 years) in the first 100 days post-transplant for the prevention of systemic and local infections, interstitial pneumonia of infectious and

**Table 2** Harada Scoring system to predict response to IVIG in Kawasaki disease (given during first 9 days of onset of disease)

Predictor	Value
White cell count	$\geq 12 \times 10^9/\text{L}$
Platelet count	$\leq 3.5 \times 10^9/\text{L}$
C-reactive protein	$\geq 40 \text{ mg/L}$
Hematocrit	$< 35\%$
Albumin	$< 35 \text{ g/L}$
Age	$\leq 12 \text{ months}$
Sex	Male

Score 1 for each category; IVIG indicated if Score  $\geq 4$  in the acute phase; IVIG not indicated if Score  $< 3$ .

idiopathic etiologies [product insert for some brands of IVIG also recommends checking acid-base balance while use of product due to possibly presence of sugars (maltose) as stabilizer in critical bone marrow transplant patients].

### Human Immunodeficiency Virus Infection

Monthly courses of IVIG treatment was shown to significantly (1) decrease the frequency of serious and minor bacterial infections (laboratory-proven and clinically diagnosed); (2) frequency of hospitalizations; (3) increased the time patients were free of serious bacterial infection and (4) preventing primary bacteremia (including *Streptococcus pneumoniae* bacteremia) including acute pneumonias.

### SIDE EFFECTS OF INTRAVENOUS IMMUNOGLOBULIN

The side effects can be broadly classified into infusion-related side effects, transfusion transmitted infections and physiological effects of increasing serum IgG levels (usually related to high-dose IVIG therapy, **Table 3**). Close monitoring is required especially for

**Table 3** Side effects of immunoglobulin therapy

Immediate reactions—usually infusion related	Mild to moderate reactions: Headache, chill, nausea, backache, muscle pain (up to 1% of reactions); majority of cases this is related to the rate or speed of infusion <i>Severe:</i> Anaphylaxis with IVIG products; the premise with most of these are due to anti-IgA antibodies in IgA-deficient patients and IgA levels in IVIG products
Intravenous immunoglobulin transfusion-related infections	<i>Hepatitis C:</i> Several outbreaks to date in medical literature; this led to the additional antiviral steps in the manufacturing process (last known outbreak in 2001) <i>Prions:</i> No documented case of clear cut transmission; prion filtration step also introduced by some manufacturers
Effects of rise in serum IgG levels (usually related to high-dose IVIG)	<i>Renal:</i> Renal impairment (reversible in most cases, some related to maltose in products) <i>Hematological:</i> Thromboses, hemolysis, cytopenia (neutropenia) <i>Neurological:</i> Acute aseptic meningitis <i>NB:</i> Assure that patients are not volume depleted prior to the initiation of the infusion of IVIG <i>Dermatological:</i> Eczema, urticaria, erythema multiforme, vasculitis
Undesirable effects	Antibodies in IVIG preparations may interfere with the response to live viral vaccines such as measles, mumps and rubella. Therefore, use of such vaccines should be deferred until approximately 6 months after IVIG administration Response to BCG vaccine is not affected by IVIG therapy

Abbreviations: IVIG, intravenous immunoglobulin; BCG, Bacillus Calmette-Guérin.

the first few doses when patients develop chills and rigor, which becomes less common as they progress through several infusions. Intercurrent infections must always be treated with antibiotics and patients examined before commencing infusions to avoid wastage of product. A checklist of training needs must be met before patients can be considered safe for administering their infusions at home.

### Infusion-related Side Effects

Common reactions associated with infusions are immediate and typically include headaches, flushing, chills, myalgia, arthralgia, nausea/vomiting and abdominal pain. Moderate to severe reactions are uncommon and usually seen with initial infusions that include chest tightness, hives, including (rarely) anaphylactic reactions in some patients. Immediate reactions need to be recognized as minor ones can be avoided or diminished by lowering the infusion rate or stopping the infusion for some time. Patients should be treated with oral paracetamol, antihistamine and the infusion restarted or continued at a slow rate. Severe reactions will require immediate cessation of infusion, and treatment with hydrocortisone, adrenaline, bronchodilators and antihistamines. After a severe reaction, switching to a different brand of IVIG should be considered.

### Side Effects of High-dose Intravenous Immunoglobulin Therapy

A serious and late reaction that is almost always seen with high-dose IVIG is the aseptic meningitis syndrome. This usually begins within several hours to 2 days following IVIG and is characterized by severe headache, nuchal rigidity, drowsiness, fever, photophobia, painful eye movements, and nausea and vomiting. Cerebrospinal fluid studies are recommended and frequently positive with pleocytosis up to several thousand cells per mm<sup>3</sup> (granulocytes), and elevated protein levels up to several hundred mg/dL.

### Intravenous Immunoglobulin-induced Cytopenia including Neutropenia

Intravenous immunoglobulin products from various manufacturers when used in high doses (2 g/kg) have been reported to induce

neutropenia, and reports including a retrospective comparative cohort study on children with ITP that showed IVIG therapy resulted in significantly more neutropenic episodes (18 of 64 IVIG courses, 28%) than anti-D therapy (0 of 64, 0%). The reassuring fact is that IVIG-induced neutropenia is transient (counts return to normal within 2 weeks) and apart from oral ulcers, no severe infectious complications have been reported to occur during the episode.

The autoantibodies in IVIG preparations that potentially lead to neutropenia are: (1) antineutrophil antibodies, atypical antineutrophil cytoplasmic antibodies (ANCA) and antiSiglec-9 (sialic acid-binding Ig-like lectin, Siglec) antibodies. Others have suggested that increase in leukocyte aggregation by IVIG leads to neutropenia. It is possible that IVIG preparations bind to neutrophils in an FcγR-dependent manner leading to neutropenia, but findings of significant titers of atypical ANCAs in various IVIG batches that were capable of inducing peroxide generation in TNFα-primed human neutrophils in FcγR-independent manner also merit consideration of whether this can lead to neutropenia.

### Intrinsic Differences Exist between Commercial IVIG Preparations

Commercially available IVIG preparations do not provide information on the glycosylation status of the IgG in the product. Even when concentration of soluble molecules, such as CD4 or IgA levels, are concerned, there are differences within products (**Table 4**), although why side effects are observed in IgA-deficient patients with a low level IgA in an IVIG product, versus no clinically significant effects in a very low versus low level IgA product are not known, suggests other mechanisms may be at play. It would be interesting to note that perhaps contain only a small fraction of the IgG in IVIG products is sialylated IgG (**Fig. 2**), and thus high doses are required to have a clinically significant immunomodulatory effect when used in autoimmune diseases like ITP, *Guillain-Barré syndrome* and myasthenic crisis. Significant differences observed in Fc sialylation between commercial IVIG preparations may result during the purification process and antiviral steps employed (pH 4/pepsin treatment, caprylate or chromatography, SD treatment) which differ between manufacturers (**Table 4**).

**Table 4** Comparison of various commercial immunoglobulin products

Product	Manufacturer	Stabilizers and pH	Viral inactivation steps
Gamma IV (5% lyophilized)	Bharat Serum and Vaccines Limited, India	9–11% maltose pH 4–5	Pasteurization, solvent/detergent, PEG precipitation, pH 4
Octagam (IV, 5%)	Octapharma, UK	100 mg/mL maltose, Triton X-100, TNBP (pH 5.1–6.0)	Solvent/detergent, pH 4 incubation, ultrafiltration, chromatography
Gamimune N (IV, 10%)	Talecris Biotherapeutics Inc., Research Triangle Park, NC 27709 USA	0.16–0.24 M glycine Buffer capacity 35 mEq/L; osmolality is 274 mOsmol/kg solvent (pH 4.25)	Solvent/detergent, pH 4 incubation, ultrafiltration, chromatography
Flebogamma (IV, 5%)	Grifols, Spain	5% D-sorbitol, PEG (pH 5.0–6.0)	Pasteurization, solvent/detergent, double sequential nanofiltration, fraction precipitation, PEG precipitation, pH 4
Sandoglobulin® NF Liquid (IV, 12%)	CSL Behring, Switzerland	L-proline, L-isoleucine, nicotinamide	Depth filtration, pH 4/pepsin, nanofiltration
Subcuvia (SC, 16%)	Baxter AG, Industriestrasse 67, A-1221 Vienna	Glycine, sodium chloride	Ultrafiltration, chromatography, solvent/detergent
Subgam® (SC, 14–18%)	BPL Bio Products Laboratory, Elstree, Hertfordshire, UK	Sodium acetate trihydrate, sodium chloride, glycine, sodium hydroxide, polysorbate 80, HCl for pH adjustment	Ion exchange chromatography, solvent/detergent (6 hr at 37°C), low pH incubation
Vivaglobin (SC, 16%)	CSL Behring, Switzerland	Glycine, sodium chloride, HCl, NaOH for pH adjustment (pH 6.4–7.2)	Depth filtration, pH 4/pepsin, nanofiltration

**Abbreviations:** IV, intravenous; SC, subcutaneous; PEG, polyethylene glycol; TNBP, tri-n-butyl phosphate [part of solvent/detergent (S/D) treatment process that is a mixture of TNBP and Triton X-100, highly effective against enveloped viruses]; treatment with pepsin at pH 4 rapidly inactivates lipid-enveloped viruses; cold ethanol fractionation (ethanol at low pH) is first step for all products and is virucidal (HIV).

### IN A NUTSHELL

1. Intravenous immunoglobulin is a blood product, and all precautions for safe use must be taken as per any blood product.
2. Intravenous immunoglobulin therapy has unequivocal role in the management of primary immunodeficiency disorders.
3. For some autoimmune diseases, especially KD, IVIG plays a crucial role and recommended as the first choice of treatment.
4. Serious reactions with IVIG can occur especially in high doses, but does not necessarily mean alternative products cannot be used.
5. All IVIG products are different, and it is recommended that named products are prescribed to patients to help in tracking transfusion transmitted diseases should they occur.

## Chapter 4.6

# Approach to a Child with Allergic Disorder

H Paramesh

In the year 1819, John Bostock presented his paper on allergic rhinitis which took him 9 years to collect 28 cases. He was the first one to state that in mid-June patients feel itching of eyes (conjunctivitis) followed by sneezing, runny nose (allergic rhinitis) later leads to chest tightness (asthma). Now we are recognizing it as united airway disease.

The development of allergic inflammatory responses starting with intrauterine environment extends through the early years of life. Although one has allergic traits, the final expression of an individual's atopic background is highly influenced by various environmental exposures. The important environmental influences are the timing, dose of exposures, early infections, home environment and exposure to environmental pollution. Understanding the natural history of allergic diseases and the interventions that may modify the development of allergy is essential in determining prognosis and providing advice for children at risk for allergic sensitization and disease. This chapter will focus on clinical and laboratory evaluation and basic principles of management of children with common allergic disorders.

## PATHOPHYSIOLOGY

There are many types of cells, which play different roles in induction of allergy.

- **Epithelial cells** They form the major barrier to the outside world.
- **Goblet and mucus glands** Secrete mucus, which forms a layer above the epithelium so that the allergen or germs will slide away.
- **Dendritic cells** Act like immigration officers and make sure the protein, bacteria or parasites cannot pass through undetected. They break the foreign protein into small fragments called epitopes and present the same to T-lymphocytes to decide what action to be taken.
- **T-lymphocytes** Are the brains of the immune system and they decode the further course of action on allergen protein.

- **B-lymphocytes** Produce antibodies and arm the mast cells for activation.
- **Mast cells** Muscle man of immune system, produce histamine and other aggressive chemicals. In addition, they signal other cells for help, the eosinophils. Usually mast cells are beneath the epithelium but when an allergic attack begins they start migrating up between the epithelial cells.
- **Eosinophils** These cells produce potent proteins like major basic protein, cationic protein, eosinophil derived neurotoxin and eosinophil peroxidase. These proteins are toxic to parasites and also attack the epithelium and sensory nerves causing hyper-response to nonallergic stimuli.
- **Neutrophils** It is a primary emergency cell of the immune system for any infection.

When sensitized mast cell is re-exposed to allergen there is an early phase reaction in few minutes where degranulation occurs, releasing preformed histamine and proteases. Mediators like cysteinyl leukotrienes prostaglandins, platelet activating factor, bradykinin, interleukins, tumor necrosis factor, granulocyte-monocyte colony-stimulating factor (GM-CSF) are produced causing effects on blood vessels and nerve. In the late phase response which occurs in 2–8 hours postallergen exposure, the chemokines released by mast cells attract eosinophil, basophil, monocyte, lymphocytes causing infiltration and inflammation. The cascade of allergic reaction is shown in **Figure 1**.

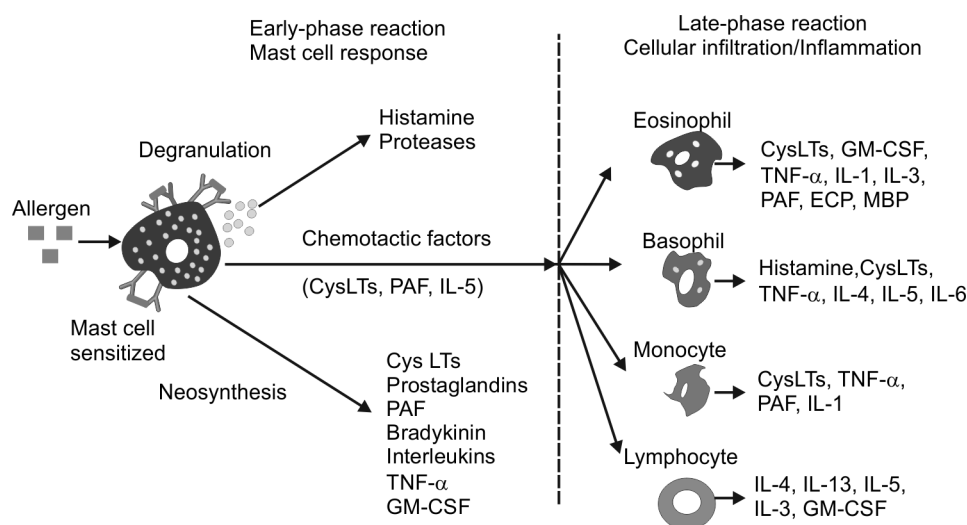

## CLINICAL EVALUATION

### Atopic Dermatitis

The clinician has to suspect atopic dermatitis with six basic criteria: History of flexural dermatitis; onset under 2 years of age; presence of itching rashes on facial, extensor surface involvement in infancy, flexural area in childhood and adolescents; personal and family history of atopy; history of dry skin; and visible flexural dermatitis with lichenification. The diagnosis of atopic dermatitis cannot be made without the history of itching. The itching intensifies in the evening and disrupts the sleep.

### Allergic Rhinitis

Allergic rhinitis is a chronic inflammatory disease of the upper airway. Due to the poor perception of symptoms and severity

**Figure 1** The allergic cascade

**Abbreviations:** CysLTs, cysteinyl leukotrienes; PAF, platelet activating factor; IL, interleukin; TNF, tumor necrosis factor; GM-CSF, granulocyte-monocyte colony-stimulating factor; ECP, eosinophil cationic protein; MBP, major basic protein.

by the doctor and patients, it is often treated as recurrent upper respiratory infection. In allergic rhinitis, the four major symptoms are sneezing, itching, rhinorrhea and nasal congestion. Any two or more of these symptoms for more than 1 hour for most of the days is diagnostic of allergic rhinitis. In addition, ask for nasal sniffing, lacrimation, headache, palatal pruritus, snoring, mouth breathing, bruxism and sleep difficulty.

### Asthma

Diagnosis of asthma in under 5-year-old is a challenge, since there is no objective supporting evidence. Usual symptoms consist of recurrent or persistent wheeze, cough, dyspnea with chest tightness, worsening at night and early morning, exacerbation with viral infection and on exposure to allergens, weather changes and with physical and emotional stress along with personal and family history of atopy. In a child in whom lung function shows more than 12% improvement after administration of nebulized bronchodilators, is an objective supportive evidence for diagnosis of asthma.

A few pointers of allergic airway diseases are listed in **Box 1**.

#### BOX 1 When to suspect allergic airway disease?

- Family history of atopy
- History of other atopic features in the child
- Afebrile episodes of respiratory distress
- Recurrence with complete clearance in between
- Sneezing with no purulent discharges (unless with secondary infection)
- Do not respond to antibiotics
- Responds to antihistamines and bronchodilators
- Usually same site involved, like middle lobe atelectasis, in asthmatics under the age of 5 years due to lack of lung collaterals
- These children have lymph nodes unlike in immune deficiency diseases.
- They have seasonal pattern.

### LABORATORY EVALUATION

Laboratory evaluation is aimed to confirm atopy, measure and assess the degree of airway obstruction variability and reversibility, and to look for features of inflammation and hypersensitivity.

### Tests to Confirm Allergic Background

Eosinophilia ( $> 4\%$ ) is suggestive; however worm infestations so common in our country can also cause eosinophilia. Absolute eosinophilia more than 1,500/cu mm or eosinophilia of 20% is suggestive of a systemic problem other than allergy. Nasal smear eosinophilia more than 5% is suggestive of allergic rhinitis. The nasal mucosal pH is alkaline in allergy but it is acidic with infective rhinitis.

### Tests to Measure Airway Obstruction and Reversibility

In allergic rhinitis, one can measure respiratory airflow and assess nasal airway resistance and their response to treatment. Spirometry can help diagnose airway obstruction in large, medium and small airways and can assess the severity. Asthmatics have low forced expiratory volume in 1 second ( $FEV_1$ ) and low forced vital capacity (FVC) and  $FEV_1$  ratio and low forced expiratory flow (FEF). Peak expiratory flow rate measurement is simple, quick and less expensive. It helps in finding response to bronchodilators and is beneficial for follow-up cases and it is a must instruments in the clinic. It measures large and medium airway dysfunction and is effort dependent. Impulse oscillometry is noneffort dependent measure of central and peripheral airway disease in all age group. Fractional exhaled nitric oxide (FeNO) measuring is a promising test but needs standardization. Other tests for bronchial hypersensitivity include *challenge tests* with histamine, methacholine and exercise.

### Tests to Confirm Atopy

These have been described in Chapter 2 of this Section and include measurement of serum immunoglobulin E (IgE), skin prick test, patch test, and radioallergosorbent test.

### MANAGEMENT OF ALLERGIC DISEASE

Management involves education, avoiding allergens and irritants, pharmacotherapy, immunotherapy and regular follow-up (**Fig. 2**). Specific drug management of individual disorders is detailed in respective chapters.

**Figure 2** Management issues in allergic disorders

### Immunotherapy

Immunotherapy is an effective mode of therapy in allergic rhinitis and asthma in reducing the sensitization to new allergens and preventing the allergic march from allergic rhinitis to asthma. The effect persists even after discontinuation of therapy for 5 years and may help in preventing airway remodeling. Sublingual route is the most preferred route as it is painless, child friendly and carried out at home with allergists monitoring.

### Anti-IgE Therapy

Omalizumab is a treatment option in patients with elevated specific IgE level. It down regulates the number of IgE receptors and tissue eosinophils and mast cells. It is recommended in children above 5 years. Only drawback is its cost and its potential risk to increase helminthic infections.

### Parental Education

It should be stressed that allergy is a noncontagious disease, does not spread to others; the main pathology is a chronic inflammation of skin or airways. Controller medicines should be used for a long time. Parents need to identify the triggers and remove them from the immediate environment of the child. The home environment should be made smoke free. Pets are not a major concern but they should not share the bedroom with children. For better control of the disease better compliance of medicines with proper technique is essential. Always involve grandparents in our culture along with parents for better compliance.

### Follow-up

Monitoring the asthma and allergic rhinitis children is very important in terms of developing a teamwork and gaining confidence and trust in disease control is assessed at regular intervals of 3 months in a stable patient and always assess the technique of inhalation, dosage, quality of life, sleep and activity. The dose has to be reduced by 25–50% every 3 months and the last drug used should be the first one to

go. Always infuse confidence, trust and positive approach to life, and plan according to social economic determinants of family.

### IN A NUTSHELL

1. Allergic diseases are increasing globally more so in developing countries.
2. Rapid urbanization is one of the major contributing factors.
3. Urban children suffer more from allergic manifestations than rural children.
4. Allergy is a chronic inflammation affecting skin and respiratory system.
5. Allergy is an interaction of genetics and the environment.
6. Immunotherapy in pediatric age group does help in preventing *allergic march*.
7. Encourage traditional food habits, good cross ventilated houses to build to our needs and yoga exercise.

# Section 5 FLUID AND ELECTROLYTES

Section Editor Rakesh Lodha

## Chapter 5.1 Body Fluids

Raghuvamsi Chaitra, Suchitra Ranjit

The homeostasis of fluid in the human body remains remarkably constant in a wide variety of conditions. The regulation is complex and is essential for optimal functioning of every organ system in the body. In health, water homeostasis is determined by the intake and output of water and its distribution in the body. However, during illnesses this balance is lost leading to deterioration and numerous complications.

### FLUID DISTRIBUTION

In health, water comprises approximately 60% of the total body weight (BW) in young adult males and about 50% in a young adult female. Since adipose tissue has less water, an obese person will have proportionately lower body water content in comparison to a lean individual. Neonates have water comprising up to 80% of BW and this gradually decreases with age (**Fig. 1**). Of the total body water, two-third (40% of BW) is intracellular fluid (ICF) and one-third (20% of BW) is extracellular fluid (ECF) (**Fig. 2**).

The ECF compartment is divided into the interstitial fluid (fluid in between tissue cells), the blood (plasma) and another small compartment of fluid known as transcellular fluid. This compartment includes fluid in the synovial, peritoneal, pericardial, and intraocular spaces, as well as the cerebrospinal fluid; it is usually considered to be a specialized type of ECF.

**Figure 1** Distribution of body water. Shaded area represents amount of body water

### Constituents of Extracellular and Intracellular Fluids

Both the ECF and ICF contain differing concentrations of electrically charged ions. The major cation (positively charged) in the ECF is sodium and potassium is the major cation in the ICF. The major negatively charged anion in the ECF is chloride, while phosphate and proteins comprise the anions in the ICF (**Table 1**).

A *solvent* is a liquid, solid, or gas into which another solid, liquid, or gaseous substance can dissolve (the *solute*). The result is a *solution*, which is in the same physical state as the solvent, for example, sugar in water. To form a solution, the solvent and solute undergo a reaction with breaking and forming of physical bonds. This is contrasted with a mixture where no physical or chemical reaction occurs when one substance is added to another, and the two remain separate.

Within the human body, fluid has a dual role as it is simultaneously a solution and a mixture at the same time. The solvent is water; the solutes are many including sodium, potassium, and chloride ions, other solute molecules, e.g., sugar and urea, and also gases including oxygen and carbon dioxide. Intracellular and ECF contains proteins, while the intravascular fluid contains

**Figure 2** Body fluid compartments  
Abbreviations: ECF, extracellular fluid; ICF, intracellular fluid.

**Table 1** Osmolar substances in extracellular and intracellular fluids

	Plasma (mOsm/L H <sub>2</sub> O)	Interstitial fluid (mOsm/L H <sub>2</sub> O)	Intracellular fluid (mOsm/L H <sub>2</sub> O)
Sodium	142	139	14
Potassium	4.2	4.0	140
Calcium	1.3	1.2	0
Magnesium	0.8	0.7	20
Bicarbonate	108	108	4
Amino acids	2	2	8
Lactate	1.2	1.2	1.5
Glucose	5.6	5.6	
Urea	4	4	4

proteins, fats, and blood cells making these fluids mixtures as well as solutions.

### Principles of Regulation of Fluid Exchange and Osmotic Equilibrium between ICF and ECF

**Osmolarity and osmolality** Osmoles are units used to express the osmotic activity of solutes in body fluids such that one mole ( $6.02 \times 10^{23}$  molecules) of solute particles has osmotic activity equal to 1 Osmole/L of solution. One mole of glucose per liter of a solution has an osmolarity of 1 Osm/L while a molecule like NaCl, which dissociates into two ions, sodium and chloride, will have an osmolarity of 2 Osm/L in a solution containing 1 mol/L of NaCl. Since logistically, an osmole is too large a unit for expressing osmotic activity of solutes in the body fluids, the unit milliosmole (mOsm) (equals 1/1,000 osmole) is used.

**Osmolarity** is the number of osmoles of solute per unit volume of solution and is expressed as osmoles/L. Osmolality is the number of osmoles of solute per unit weight of solvent and is expressed as osmoles/kg. These terms are used to quantify how much of a solute is dissolved in a solution; the main difference is that when temperature changes, volumes (osmolarity) will change, but mass (osmolality) remains the same.

The osmolality of plasma may be estimated by summing the major solute particles in plasma, i.e., sodium, potassium and chloride ions, glucose, and urea. As sodium chloride and potassium chloride dissociate in a solution to form two ions each, the serum sodium and potassium ion concentrations are doubled when calculating serum osmolality.

$$\text{Plasma osmolality} = 2 * [(\text{Na} + \text{K})] + [\text{glucose}(\text{mg/dL})]/18 + [\text{BUN}(\text{mg/dL})]/2.8$$

Note: If blood urea nitrogen (BUN) is not available, use urea/6

**Tonicity** Tonicity differs from osmolality in that it is influenced only by the solutes which are unable to cross a semipermeable membrane separating two solutions. The tonicity of two solutions separated by a membrane can be described in relative terms depending on the concentration of solution, so that a solution may be as hypertonic, isotonic or hypotonic (higher, same or lower concentration respectively, of solute on one side compared to solute on the other side of the membrane).

**Diffusion** Rather than the movement of fluid, diffusion results in the movement of solutes and substances from an area of high concentration to one of low concentration (Fig. 3).

**Figure 3** Diffusion: Diffusion of molecules across a semipermeable membrane from an area of high concentration to an area of low concentration

Source: <https://www.moodle.kent.ac.uk/external/mod/book/tool/print/index.php?id=2396&chapterid=81>.

**Facilitated diffusion** The carrier molecules transport substances from high to low concentrations. This form of transport does not require energy (Fig. 4).

**Active transport** Here, substances move against concentration gradients, and the energy for this active transport is supplied by membrane ATP pumps (Fig. 5).

**Osmosis** This is the passive movement of water from a dilute solution (i.e., relatively hypotonic) to a more concentrated solution (i.e., relatively hypertonic) across a selectively permeable membrane. The permeability of the membrane is said to be selective as it permits free movement of water molecules from one side to the other but does not allow any solute particles to cross. For example, when NaCl is added to the ECF, water moves from ICF to ECF; this principle governs hypertonic saline treatment of patients with cerebral edema (Fig. 6).

**Oncotic pressure** Oncotic pressure is the osmotic pressure generated by large molecules (especially proteins) in solution.

### What Regulates the Movement of Water Between Fluid Compartments?

Selectively permeable membranes separate the intravascular, interstitial, and ICF compartments from each other. The capillary wall separates the intravascular and interstitial compartments, while the ICF and ECF compartments are separated by the cell membrane. The two membranes have different properties (Fig. 2).

**Capillary wall** The movement of fluid across a capillary wall is passive and determined by filtration and passive diffusion. Filtration is determined by hydrostatic (blood pressure) and oncotic pressures, the well-known Starling forces. These Starling forces act to drive water out of the capillary into the interstitium and, in the process, passively drag dissolved solutes with it. Diffusion refers to the movement of solutes from an area of high concentration to an area of lower concentration. The water crosses the capillary wall via the gaps between cells or directly through the cell membrane.

**Figure 4** Facilitated diffusion: Transport substances from high to low concentrations by carrier proteins  
 Source: [http://www.en.wikipedia.org/wiki/File:Scheme\\_facilitated\\_diffusion\\_in\\_cell\\_membrane-en.svg](http://www.en.wikipedia.org/wiki/File:Scheme_facilitated_diffusion_in_cell_membrane-en.svg). Accessed October 21, 2014.

**Figure 5** Active transport of solute across the cell membrane against the concentration gradient using energy  
 Abbreviations: ADP, adenosine diphosphate; ATP, adenosine triphosphate.  
 Source: [http://www.en.wikipedia.org/wiki/File:Scheme\\_sodium-potassium\\_pump-en.svg](http://www.en.wikipedia.org/wiki/File:Scheme_sodium-potassium_pump-en.svg)

**Figure 6** Osmosis: movement of water across a semipermeable membrane

**Cell membrane** The movement of most solute and water across this membrane occurs via transmembrane proteins or ion channels which provide different permeability to different solutes. In a steady state, the ICF and ECF are in osmotic equilibrium and hence, no water movement occurs.

In order for water to move between ECF and ICF, a difference in tonicity must exist between the two sides of the cell membrane. Any difference in extracellular or intracellular tonicity is due a change in the solute concentration in either fluid compartment. Water then moves by osmosis up a concentration gradient from a hypotonic to hypertonic compartment. The cell membrane is essentially impermeable to  $\text{Na}^+$  ions, and so the  $\text{Na}^+$  concentration in the ECF principally governs the distribution of water between ECF and ICF. The ECF  $\text{Na}^+$  concentration is controlled by various neuroendocrine controls via the kidneys. The net movement of fluid between the two compartments can occur in either direction and depends on the balance of various forces acting across the membrane.

## NORMAL DAILY INTAKE AND OUTPUT OF FLUID

To assure optimal functioning of the body systems, it is essential that the overall amount of body water remains constant. Appropriate distribution across all of the fluid compartments at all times is just as vital. This process whereby the body tries to ensure the correct fluid balance is maintained is called *homeostasis*. In health, as part of the body's normal function, water and electrolytes are continually being lost. These need to be replaced to maintain equilibrium. In certain situations, losses are increased, e.g., diarrhea, burns. Abnormal losses may also occur when fluid is abnormally distributed, resulting in too much in some or too little in the other body's fluid compartments, e.g., postoperatively or in sepsis. These fluid losses may be termed *sensible* meaning that it is easily seen and measured, e.g., urine output and losses from the gastrointestinal tract, while other fluid losses are often referred to as *insensible* meaning they are harder to see and measure, e.g., evaporative fluid loss from the skin and respiratory tract. Normal insensible fluid loss is 400 mL/m<sup>2</sup> of body surface area.

## Sweat

Sweating is centrally controlled by thermosensitive neurons located in the preoptic and anterior regions of the hypothalamus; this can be an important source of fluid loss as the rate of sweating can vary between 100 mL/day and 8,000 mL/day. Sweat is not pure water; it always contains a small amount (0.2–1%) of solute. At any given time, the actual electrolyte content of sweat varies depending on emotional state, diet, exercise, acclimatization, and some hereditary factors, e.g., cystic fibrosis. Sodium is the major electrolyte lost in sweat and losses can range from 5 mmol/day to 50 mmol/day (**Table 2**). Sweating is different from insensible loss from the skin; the latter is lost by evaporation which is pure water.

## Urine

The formation of urine is a complex process and occurs due to highly sophisticated mechanisms including glomerular filtration, tubular secretion and reabsorption. The volume and composition of urine can vary widely and depends principally on the intravascular fluid volume and composition as the state of kidney function. For a patient with normal hydration and kidney function, there is an obligatory volume of urine produced and electrolyte loss in a 24-hour-period. The obligatory loss is a result of the daily solute intake and metabolic waste products, e.g., urea, creatinine and drug metabolites, all of which increase ECF tonicity, and need to be excreted. For healthy patients with normal renal function urine osmolality can range from 50 mOsm/kg to 100 mOsm/kg H<sub>2</sub>O up to around 1,200 mOsm/kg H<sub>2</sub>O.

**Table 2** Electrolyte composition of various body fluids

Fluid	$\text{Na}^+$ (mEq/L)	$\text{K}^+$ (mEq/L)	$\text{Cl}^-$ (mEq/L)
Gastric	20–80	5–20	100–150
Pancreatic	120–140	5–15	90–120
Small bowel	100–140	5–15	90–130
Bile	120–140	5–15	80–120
Ileostomy	45–135	3–15	20–115
Diarrhea	10–90	10–80	10–110
Burns	140	5	110
Sweat			
Normal	10–30	3–10	10–35
Cystic fibrosis	50–130	5–25	50–110

Alterations in the intravascular fluid volume and osmolality affect the kidney's glomerular filtration rate and tubular resorption resulting in a variable amount of sodium chloride in the filtrate reaching the distal tubule of the kidney. This is detected by a region called the *juxtaglomerular apparatus* (JGA) which is responsible for producing and secreting the hormone renin which controls the renin-angiotensin-aldosterone system (RAAS).

When a patient is hypovolemic (low circulating intravascular volume) or has high osmolality (dehydration), a higher concentration of sodium chloride in the filtrate is presented to the JGA, stimulating an increase in renin production thereby activating the RAAS. One of the actions of the RAAS is to increase sodium and water reabsorption in the proximal tubule (by the action of angiotensin II) and in the collecting ducts [by the action of aldosterone and antidiuretic hormone (ADH)]. The increased water resorbed will tend to return intravascular fluid volume and osmolality toward normal.

## Gastrointestinal Tract

In a normal person, over a day, large volumes of electrolyte-rich fluid are secreted into and reabsorbed from the gut in a continuous manner. The source of the gut fluid is oral fluid consumed by the individual, and also secretions of saliva, gastric juices, and small intestine secretions. Virtually all ( $\approx 98\%$ ) of this fluid is reabsorbed resulting in only 200 mL/day of fecal water loss. This highly efficient continuous recycling of fluid results in a very small fraction of fluid remaining in the gut lumen at any one time; this is considered the transcellular fluid. If the continuous recycling mechanism is disturbed on account of persistent diarrhea or vomiting, then the large volumes of electrolyte-rich fluid secreted proximally will be lost and not be reabsorbed distally. This results in fluid and electrolyte losses culminating in dehydration of the individual.

## Respiratory Tract

Exhaled gases from the respiratory tract are fully saturated with water vapor but contain no solutes. The respiratory fluid loss is usually in consequential, but may be considerable in a tachypneic patient with high minute ventilation, especially if the patient is administered dry gases, e.g., nonhumidified oxygen.

## HORMONAL MECHANISMS

Vasopressin (antidiuretic hormone, ADH) is an important hormone which is responsible for maintaining intravascular volume and osmolality. Vasopressin is stored in the posterior pituitary and its secretion is increased in various conditions, such as hypovolemia,

**Figure 7** Body fluid distribution  
Abbreviations: BW, body weight; ECF, extracellular fluid;  
ICF, intracellular fluid.

hyperosmolality, emotional upsets, pain and stress. Vasopressin act on V2 receptors on the basolateral membrane of the renal collecting ducts, leading to water reabsorption via newly inserted aquaporin water channels. Angiotensin II and aldosterone, along with ADH pay a key role in the control of ECF osmolality and sodium concentration.

### Applied Physiology

Example to calculate fluid distribution in different compartments in a child weighing 20 kg using the flow diagram in **Figure 7**.

Total body water	: $0.6 \times 20 \text{ kg}$	= 12 liters
ECF volume	: $0.2 \times 20 \text{ kg}$	= 4 liters
ICF volume	: $0.4 \times 20 \text{ kg}$	= 8 liters
Interstitial fluid	: $0.75 \times 4 \text{ liters}$	= 3 liters
Plasma	: $0.25 \times 4 \text{ liters}$	= 1 liter

*What happens to ECF volume when fluids of various tonicity are infused?*

- If an isotonic saline solution (0.9% NaCl or Ringer's lactate) is infused into the ECF compartment, the osmolality of the ECF does not change; therefore, no osmosis occurs through the cell membranes.
- If a hypotonic solution (isolyte P, 0.45% NaCl) infused into the ECF, the osmolality of the ECF decreases and some of the extracellular water diffuses into the cells until the intracellular and extracellular compartments have the same osmolality.
- If a hypertonic solution (3% NaCl, mannitol) is infused into the ECF compartment, the ECF osmolality increases and

causes osmosis of water out of the cells into the extracellular compartment. This causes increase in extracellular volume and decrease in intracellular volume.

### IN A NUTSHELL

1. Water is a major constituent of the human body, accounting for 60% of the BW. Body water is divided between two major compartments ICF and ECF. Two-thirds of the water is in the ICF, and one-third is in the ECF.
2. Osmotic pressure gradients between ICF and ECF are responsible for water movement between these compartments.
3. The ECF is divided into a vascular compartment (plasma) and an interstitial fluid compartment. Starling forces across capillaries determine the exchange of fluid between these compartments.
4. Sodium is the major cation of ECF and potassium is the major cation of the ICF.
5. Tonicity is a way of describing the relative solute concentrations of two solutions which are separated by a selectively-permeable membrane.
6. Daily water intake should balance daily water loss (sensible plus insensible loss) to maintain tight fluid balance which is required for optimal functions of tissue.

## Chapter 5.2

# Maintenance Fluid Therapy

Banani Poddar, Kirti M Naranje

Intravenous (IV) fluid therapy is the most common medical intervention in hospitalized children. It is one of the essential supportive care treatments for a variety of diseases. Traditionally, IV fluids are intended to provide free water and electrolytes in a fasting patient. However, with rapid advances in medical care, IV fluid therapy has become more challenging and complex. Five common reasons to infuse IV fluid in a hospitalized child are listed in **Box 1**. This chapter will focus on maintenance fluid therapy in children and does not pertain to neonates who have their own distinctive fluid and electrolyte requirement.

### BOX 1 Indications for IV fluids

- Maintaining hemodynamics
- Normalizing intracellular fluid volume
- Replacing ongoing renal and nonrenal losses
- Providing glucose to brain, and
- Providing maintenance fluids to match the daily insensible water losses.

## MAINTENANCE FLUIDS

Maintenance fluid therapy, in general, implies that a precise volume and electrolyte content is prescribed to a child who cannot be fed orally or via feeding tube, assuming that fluid and electrolyte balance is normal to begin with. It intends to maintain homeostasis till the time the child is able to take orally and control his own fluid balance. Maintenance fluids are solutions containing water, dextrose and electrolytes. The major objectives of any maintenance fluid therapy are to: (1) prevent dehydration; (2) prevent electrolyte disturbances; (3) prevent ketoacidosis, and (4) prevent protein degradation.

Maintenance therapy is most frequently used in preoperative and postoperative surgical children, though a large proportion of acutely ill children do require fluids as maintenance requirement. It is important to identify when to administer maintenance fluids in a child. A healthy adolescent can easily tolerate 12–18 hours of fasting as compared to an infant who needs maintenance fluids within 8 hours of being kept nil per orally. This is because infants tend to get dehydrated more rapidly than older children. Similarly, it is essential to make sure that a child is not receiving maintenance fluids for an indefinite period in hospital. These fluids are typically devoid of sufficient calories, proteins, fats, vitamins and minerals and can cause 0.5–1% body weight loss daily. Maintenance fluids are meant to be used for shorter time periods. Those children in whom enteral feeds cannot be started beyond a few days should be shifted on to total parenteral nutrition in order to meet adequate nutritional requirements. This is especially true in undernourished children.

## Estimation of Electrolyte Free Water

One of the fundamental constituents of maintenance fluid therapy is water because body loses water daily through various routes. These can be via urine or stool (measurable) or evaporative losses such as through skin, lungs (nonmeasurable). Similarly, there is obligatory loss of electrolytes through body daily. **Table 1** depicts the average daily water and electrolyte losses through various organ systems. One of the purposes of any maintenance fluid is to replace these insensible water and electrolyte losses. Almost 60% water loss is through urine. The kidneys play an important role in regulation of water balance and have the capacity to concentrate

or dilute urine in response to wide variations in fluid intake. This is advantageous since the majority of traditional formulas for estimating maintenance water need lack absolute precision. Provision of electrolyte-free water (EFW) via maintenance fluid gives adequate margin of safety for the body homeostatic mechanisms to adjust urinary water losses with the aim to prevent disturbances in hydration status of a child.

Conventionally, maintenance fluid volumes are calculated by formulas based upon body weight (**Table 2**). Other methods include those based on body surface area (Crawford) and age (Wallace). The body weight method was first published in 1957 in a landmark study by Holliday and Segar. Since then, it has been most popular, convenient and universally accepted for estimation of water requirements. This method assumes that fluid losses occur normally (insensible or obligatory losses) and approximately 1 mL equals 1 kcal energy generated. In addition, alterations in maintenance volume are required in conditions whenever there are increased losses through skin, lungs or urine (**Table 3**). Thus, maintenance fluid volume needs to be increased in situations of excessive transcutaneous losses like fever, burns, undue sweating, and use of radiant warmer or phototherapy. It also needs to be augmented in a tachypneic or tracheostomized child who is not receiving humidified oxygen and in those who have excessive gastrointestinal (diarrhea, nasogastric suction, vomiting) as well as urinary losses (polyuria). The causes for decreased water requirement include oliguria/anuria, use of humidifier for oxygen therapy, hypothyroidism and use of incubator.

Recently, there has been a lot of criticism of the traditional weight-based formulas, mainly for overestimating EFW volumes in maintenance therapy. Firstly, these calculations are derived from findings in healthy children and cannot be extrapolated to critically sick children due to differing physiology. Secondly, this method of estimating EFW requirements is based on caloric

**Table 1** The daily fluid and electrolyte losses (expressed as per 100 calories of metabolism per day)

Route	Water (mL/kg)	Na(mEq/kg)	K(mEq/kg)
Evaporative			
Lung	15	0	0
Skin	40	0.1	0.2
Stool	5	0.1	0.2
Urine	65	3.0	2.0
<b>Total</b>	<b>125</b>	<b>3.2</b>	<b>2.4</b>
Metabolic water produced	-10	-	-
<b>Net balance</b>	<b>115</b>	<b>3.2</b>	<b>2.4</b>

**Table 2** Holliday and Segar calculation of maintenance water volumes based on body weight. Also shown are the hourly maintenance fluid rates

Body weight*	Maintenance water #	Hourly maintenance fluid rate†
Till 10 kg	100 mL/kg	4 mL/kg/h
10–20 kg	1,000 mL + 50 mL for every kg >10 kg	40 mL/h + 2 mL/kg/h for each kg >10 kg
20 kg and above	1,500 mL + 20 mL for every kg above 20 kg	60 mL/h + 1 mL/kg/h for each kg above 20 kg

\* Body weight (BW) should preferably be child's lean body weight estimated by using 50th percentile of BW for the child's height

# Upper limit for maintenance water is 2.4 liters for an adult size patient

† Maximum fluid rate should be restricted to 100 mL/h

**Table 3** Required alterations in maintenance fluid volume in diverse clinical states

Clinical state	Route	Adjustments in maintenance fluid volume
Fever (persistent)	Skin	Increase volume by 10–15% for every 1°C above 38°C
Tachypnea Tracheostomy	Lungs	Increase volume by 20–50% (note: do not increase if child is receiving humidified oxygen therapy either noninvasively or via ventilator)
Polyuria	Urinary	Measure actual urinary output every 1–2 hourly and add to maintenance volume for next 1–2 hours
Anuria		Exclude urinary loss from maintenance volume
Oliguria		Measure actual urinary output every 6–12 hourly and add to maintenance volume for next 6–12 hours

expenditure and energy production. The calculation of energy expenditure based on body weight has been found to be unreliable in acute diseased states. Also, the insensible losses in a sick child is varied due to diminished muscle activity, decreased dietary intake, altered cutaneous blood flow and environmental factors such as temperature, humidity and air circulation. The net energy expenditure in critically ill children may be as low as 50–60 kcal/kg/day. A low metabolic state because of physical immobility, use of sedation, muscle relaxants and mechanical ventilation contributes to low caloric requirements in acute illness. Further, in critically sick children there are various osmotic (hypovolemia, hypotension, serum osmolality) and nonosmotic (pain, drugs, anesthetic agents, nausea, stress) stimuli for the release of vasopressin from posterior pituitary which leads to accumulation of EFW. Lastly, EFW may be generated by kidneys due to *desalination* phenomenon; it has a poorly understood mechanism and is presumed to occur as a result of excretion of hypertonic urine in children who receive isotonic or near-isotonic fluids.

### Composition of Maintenance Intravenous Fluids

As stated earlier, the maintenance fluid normally contains glucose, water and electrolytes. The commonest IV fluids used in day to day practice are 0.2% NaCl and 0.45% NaCl in 5% dextrose. Sodium and

potassium are the chief electrolytes required in a typical maintenance fluid regime. Sodium and potassium can be added at 3.0 mEq/kg/day and 2.0 mEq/kg/day to the fluid. This is based on estimates derived from dietary requirement and sodium intake to urinary excretion ratio in healthy breast-fed infants. IV solutions are also commercially available with or without added potassium chloride at concentration of 10 mEq/L and 20 mEq/L. Other commonly available IV fluids are listed in **Table 4**. Other electrolytes like calcium, magnesium, phosphate, bicarbonate and vitamins and minerals can be added to maintenance fluid in desired concentration. It may be a good idea to start with 0.45% normal saline along with 5% dextrose and 20 mEq/L of potassium chloride (provided child is passing adequate urine) as maintenance therapy in an unwell child. However, type of fluid should be modified according to clinical state. The advantages of commercially available IV fluids are that they are ready to use, requires no preparation time and are less costly. Conversely, IV solution can be customized and prepared in hospital pharmacy; the disadvantage being more cost and time of preparation and risk of contamination if strict aseptic precautions are not followed. Mixing various IV fluids to obtain the desired content of glucose and electrolytes at the bedside is a frequent practice but can be a source of infection if attention is not paid to asepsis.

### Glucose and Maintenance Fluids

In general, dextrose forms one of the vital components of maintenance fluid in children in order to avoid the risk of hypoglycemia. However, hyperglycemia has been found to be associated with negative prognosis in critically ill children, especially in traumatic brain injury and burns. Further, hyperglycemia has been found to reduce immune function and increase mortality risk in sick children. Therefore it may be judicious to avoid glucose in maintenance fluid in older children, particularly in vulnerable group of patients, such as traumatic brain injury and burns, with a caution to monitor blood sugar levels vigilantly in order to avoid hypoglycemia. For smaller infants it is desirable to keep a minimum glucose infusion rate of 4 mg/kg/min and monitor blood sugar levels in order to prevent hypoglycemic effects on developing brain. The energy generated from the commonly used IV fluids containing 5% dextrose is 17 calories/100 mL. This accounts for around 20% of daily caloric needs. The aim is to prevent generation of ketones and minimize protein degradation in the body. However, it is not sufficient enough to prevent weight loss; hence the rationale for starting total parental nutrition if oral feeds cannot be started beyond a few days in a sick child.

**Table 4** Composition of commonly used intravenous solutions

Intravenous fluid	Glucose content (g/dL)	Na <sup>+</sup> K <sup>+</sup>		Concentration in mEq/L				Lactate/Acetate	Osmolality (mOsm/L)	Electrolyte*-free water (%)
		Na <sup>+</sup>	K <sup>+</sup>	Cl <sup>-</sup>	Ca <sup>++</sup>	Mg <sup>++</sup>	PO <sub>4</sub>			
5% dextrose in water (D5)	5	-	-	-	-	-	-	-	252	100
10% dextrose in water (D10)	10	-	-	-	-	-	-	-	505	100
0.2% NaCl in 5% dextrose in water (N/4 saline in 5D)	5	34	-	34	-	-	-	-	321	78
IsoLyte P in 5% dextrose in water (Iso P)	5	25	20	29	-	3	3	23 (acetate)	340	84
0.45% NaCl in 5% dextrose in water (N/2 saline in 5D)	5	77	-	77	-	-	-	-	406	50
0.9% NaCl in 5% dextrose in water (DNS)	5	154	-	154	-	-	-	-	560	0
Lactated Ringer's solution (RL)	-	130	4	109	3	-	-	28	273	16
Lactated Ringer's solution in 5% dextrose in water (RL in 5D)	5	130	4	109	3	-	-	28	525	16

## HYPOTONIC VERSUS ISOTONIC FLUIDS

One of the important considerations in selecting appropriate maintenance fluids is osmolality of the infused fluid. The normal serum osmolality in human body ranges from 285 mOsm/kg to 295 mOsm/kg. Infusing an IV fluid with low osmolality can cause movement of free water from plasma to red blood cells and may cause hemolysis. Hence, IV fluids which have osmolality equal to or slightly greater than normal plasma osmolality are safer than hypotonic fluids. Thus, infusing plain 5% dextrose in water or 0.2% or 0.45% NaCl (without dextrose) can create trouble and should be avoided. Further, recent literature suggests that hypotonic fluids are responsible for occurrence of hyponatremia with serious neurological consequences in children. To prevent the occurrence of hyponatremia as a result of IV fluid therapy, the two practices would include reducing the fluid rate and/or use of isotonic fluids as maintenance therapy, thus decreasing the accumulation of excess water and thereby its harmful effects. However, there is no consensus as to which practice is superior.

In spite of vast literature on the dangers of hypotonic maintenance fluids, a recent survey of pediatric residents found that nearly 78% continued to use hypotonic maintenance fluids in four diverse clinical circumstances classically associated with excess antidiuretic hormone (ADH) secretion. The role of isotonic fluids has been largely restricted to restore intravascular volume as a resuscitation fluid. The main concerns with the use of isotonic fluids as maintenance therapy are risk of hyperchloremic metabolic acidosis, circulatory overload in at risk patients, excess renal solute loading and hypernatremia. But these side effects have not been well-substantiated in literature. On the contrary, use of isotonic fluids may also be associated with occurrence of hyponatremia as a result of *desalination* phenomenon especially in postoperative period.

### Maintenance IV Fluids and Hyponatremia

The incidence of hyponatremia in hospitalized children has been found to vary from 9.2% to 31% as reported in different studies. It is also the commonest electrolyte abnormality found in hospitalized children. There are many factors including use of hypotonic fluids, excess solute diuresis, less caloric expenditure and overestimation of fluid requirement with traditional formulas. In addition, there are a variety of stimuli for the release of ADH in a critically sick child (as discussed earlier), which further contributes to retention of excess free water in the body leading to hyponatremia. Nonetheless, accumulation of EFW alone may not be the only mechanism for causation of hyponatremia in critically sick children; contribution of other mechanisms also needs to be explored. The signs and symptoms of hyponatremia may be subtle such as nausea and vomiting which are often attributed to other reasons. Therefore, hyponatremia is often unanticipated and under-recognized until overt signs of raised intracranial pressure or seizures develop. Since sodium is the principal cation in ECF which maintains ECF volume and regulates movement of water across cell membrane, it explicates the development of intracellular fluid retention and consequent edema in presence of significant hyponatremia. This is particularly important in smaller children who have greater intracellular fluid volume per total skull volume in their brains. Hence, even a small increase in intracellular fluid volume may cause significant cerebral edema which in turn can lead to serious neurological sequelae in children. In a recently conducted systematic review of maintenance IV fluids in hospitalized children, hypotonic fluids have been found to increase the development of hyponatremia by odds of 17 as compared to isotonic fluids. Thus, isotonic fluids may be more physiological to use as they maintain the plasma osmolality and may decrease the incidence of unfavorable effects of hyponatremia. Further, isotonic fluids may cause the ADH levels to return to normal more rapidly when compared to hypotonic fluids as reported in a study by Powell et al.

## Restricted Volume of Maintenance Fluids

What constitutes an ideal volume for maintenance fluid is still debated worldwide. Conventional calculation often leads to overestimation of required fluid volume and consequent side effects of excess free water retention including hyponatremia. Provided that the intravascular volume is maintained, maintenance fluid volume and rate can be limited up to a range of 40–66% of the standard. This view is being increasingly favored in many studies. Use of isotonic saline in such cases may not be completely helpful. Hence, restriction of maintenance fluid volumes may be a more appropriate strategy; though presently there is not much evidence in literature showing clear advantage of using restricted fluid volumes and reduction in incidence of hyponatremia. Also it is prudent to restrict fluid volumes in patients with problem of antidiuresis due to various reasons particularly renal dysfunction. Conservative fluid strategy targeting a negative or even fluid balance has also been found to be beneficial in patients with acute respiratory distress syndrome after correction of shock.

## PRESCRIBING MAINTENANCE FLUID THERAPY

Prescribing maintenance fluid therapy appears to be routine in pediatrics. However, one should not ignore the potential morbidity and mortality linked with this simple daily intervention. Hence, it is imperative that maintenance fluid in a child should be prescribed with extreme vigilance and the same care and precaution should be taken as with any drug prescription. It is important to remember that fluid administration should be tailored according to individual needs and no single fluid is ideal for all situations. There is no evidence that a single fluid is better than other and the notion that *one size fits all* does not have scientific substantiation.

While choosing appropriate maintenance fluid, one should always determine the goal and indication in each clinical scenario. Selection of fluid for maintenance therapy in acute disease states and postoperative period should not only satisfy the daily electrolyte and water requirements but should also be aimed at maintaining the tonicity balance while they are at heightened risk of developing electrolyte imbalance, particularly hyponatremia. Physiologic parameters, body weight, fluid balances and laboratory investigations like blood glucose levels and serum electrolytes should be monitored at regular intervals in order to prevent complications from maintenance fluid therapy. Holliday-Segar's formula continues to guide IV fluid prescription; however, it should be modified according to the clinical condition. Syringe infusion pumps or pediatric drip set to administer IV maintenance fluid is desirable, especially in smaller children to avoid inadvertent fluid overload.

Isotonic fluids may be more physiological to use in settings where higher osmolality needs to be maintained such as acute gastroenteritis with dehydration, severe sepsis with hypovolemia, salt losing nephropathy (Bartter syndrome, adrenal insufficiency), hypothyroidism, etc. Isotonic fluids are also indicated in conditions where there is ADH excess with or without hypovolemia such as postoperative state, central nervous system infections, pulmonary diseases (pneumonia, asthma, and bronchiolitis) and glucocorticoid insufficiency.

Conservative fluid strategy should be employed in situations of edema like congestive cardiac failure, nephrosis, cirrhosis and hypoalbuminemia. Fluid should also be limited to around 400–600 mL/square meter of body surface area in oliguric conditions such as renal failure due to acute glomerulonephritis, acute tubular necrosis and end-stage renal diseases. Recent literature also supports restricted fluid strategy in certain disease settings like acute respiratory distress syndrome and traumatic brain injury, once the intravascular volume is restored to normal.

The indications for hypotonic fluids include conditions of free water deficit (e.g., hypernatremia); renal concentrating defects

such as nephrogenic diabetes insipidus, recovery phase of acute tubular necrosis, reflux nephropathy, obstructive uropathy, tubulointerstitial nephritis, etc. The other reasons to administer hypotonic fluid are the problems of extrarenal free water loss like burns, fever, gastrointestinal losses and in premature neonates.

There are still many unanswered questions regarding IV fluid therapy in children such as ideal concentration of dextrose, ideal concentration of chloride and efficacy of half normal saline versus isotonic saline. Further research is required to clarify these concerns about maintenance IV fluid therapy in children.

### IN A NUTSHELL

1. Intravenous fluid therapy composition and rate should be tailored to the clinical situation.
2. Maintaining tonicity balance may be more important in acute disease states than just meeting the insensible water losses and daily electrolyte requirement.
3. Traditional formulas to calculate fluid requirement often overestimate the fluid needs in critically ill children.
4. Hyponatremia is the single most common electrolyte abnormality observed in hospitalized children and it has significant neurological morbidity if undiagnosed and untreated.
5. Isotonic fluid may be more physiological as maintenance therapy than hypotonic fluids.
6. Adequate monitoring of physiological and biochemical parameters including blood glucose and serum electrolytes should be done when a child is on IV fluid therapy.

## Chapter 5.3

# Acid-Base Equilibrium

Dinesh Raj, Rakesh Lodha

The acid-base equilibrium of the body is tightly regulated to maintain the systemic arterial pH between 7.35 and 7.45. This tight regulation is necessary as various enzymatic and metabolic processes function optimally in this range. Compensatory mechanisms are activated when pH crosses these limits, which attempt to restore the pH toward normal. The initial attempt to normalize the pH is made by extracellular and intracellular chemical buffering which is followed by respiratory or renal compensation. Disturbances of acid-base balance are commonly encountered in the emergency and critical care setting. A thorough understanding of the underlying pathophysiology leading to the acid-base disorders is needed to correctly diagnose and effectively manage the patient. This chapter reviews the physiology of acid-base equilibrium.

Hydrogen ion ( $H^+$ ) concentration is very closely regulated in the extracellular fluid (ECF) to maintain its concentration around 40 nmol/L (corresponding to a pH of 7.4). Despite acids and bases being added to the ECF, the compensatory mechanisms attempt to maintain the  $H^+$  concentration in a narrow range to ensure physiologic body functions. The physiological processes leading to decrease or increase in pH are referred as *acidosis* and *alkalosis*, respectively, whereas, *acidemia* and *alkalemia* indicate the state of an abnormal pH.

### NET ACID PRODUCTION

The metabolism of carbohydrates and lipids results in production of  $CO_2$ . The daily production of  $CO_2$  is in the range of 10,000–15,000 mmol/L. Apart from these volatile acids, there is generation of nonvolatile or fixed acids from the metabolism of proteins containing acidic amino acids. Byproducts of cellular metabolism (acetic acid, lactic acid, and pyruvic acid) are added to the ECF, adding to the acid load. Organic anions from diet and metabolism of basic amino acids add to the alkali load of the ECF. Apart from the volatile acids, around 1–2 mEq/kg of fixed or nonvolatile acids are generated. Lungs are responsible for the disposal of volatile acids, whereas kidneys eliminate the nonvolatile acids from the body.

### CARBON DIOXIDE TRANSPORT

An understanding of  $CO_2$  transport is important as enormous quantities of  $CO_2$  is produced in the body and exhaled by the lungs.  $CO_2$  is transported in the blood in three forms: dissolved  $CO_2$ , as carbonic acid, and bound to proteins predominantly hemoglobin. The red blood cell is responsible for the transport of around 75% of  $CO_2$ ; rest is transported in plasma.

**Dissolved  $CO_2$**  Carbon dioxide is 20 times more soluble than oxygen in blood. As a result, large quantities of  $CO_2$  can be transported dissolved in blood with little increase in partial pressure. Because of the high solubility and diffusing capacity, its partial pressure in alveoli and pulmonary end-capillaries is essentially the same.

**Carbonic acid ( $H_2CO_3$ )** The combination of  $CO_2$  and water leads to the formation of carbonic acid (a reaction accelerated by carbonic anhydrase by 5,000 times). Carbonic acid dissociates freely into  $H^+$  and  $HCO_3^-$ .

**Carbon dioxide bound to proteins**  $CO_2$  combines with the amino groups of proteins to form carbamino compounds. The

combination between  $CO_2$  and amino groups of hemoglobin forms carbaminohemoglobin ( $CO_2Hb$ ).  $CO_2Hb$  contributes more to  $CO_2$  transport as hemoglobin is three times the quantity of plasma proteins.

**Carbon dioxide transport in tissues** Carbonic anhydrase present in the red blood cell catalyzes the formation of  $H_2CO_3$  which dissociates to form  $H^+$  and  $HCO_3^-$ . RBC membrane is impermeable to  $H^+$ , which is taken up by the reduced hemoglobin (through the imidazole group of histidine).  $HCO_3^-$  diffuses out of the cell while Cl diffuses inside to maintain electrical neutrality. The dissociation constant of the imidazole group of histidine is affected by the oxygenation state of hemoglobin. The oxygen bonding is weakened in the acidic state leading to unloading of oxygen in the tissues and buffering of  $H^+$  ions released from carbonic acid.

**Carbon dioxide transport in lungs** An increase in  $CO_2$  concentration in blood causes displacement of oxygen from the hemoglobin (Bohr's effect), with the reverse also true. Binding of oxygen to hemoglobin in the pulmonary capillaries augments  $CO_2$  unloading (Haldane effect).

### BUFFER SYSTEMS

Buffers are substances which maintain the pH in a narrow range despite addition of an acid or base to the body. Buffers are able to accept or donate protons ( $H^+$ ) to regulate pH. These buffers are able to maintain pH around normal but unable to remove the acid or alkali from the body. The pH at which the buffers (weak acids or bases) are in half dissociated form is known as the *dissociation constant* or pKa. As the physiologic buffers have their pKa close to systemic pH, they function best in these ranges.

The most important buffer system is the carbonic acid-bicarbonate buffer. Addition of any acid (HA, for example) leads to conversion of bicarbonate to  $CO_2$  via the following reaction mediated by the enzyme carbonic anhydrase:

$CO_2$  is eliminated by the lungs. Bicarbonate is consumed in this reaction to buffer the acid, thereby minimizing the change in pH. The ratio of bicarbonate to carbonic acid determines the systemic arterial pH. Normally, this ratio is about 20:1. The bicarbonate-carbonic acid buffer is extremely rapid and effective.

Other important buffers include plasma proteins, phosphates (organic and inorganic) and hemoglobin. Bones also attempt to buffer by acid-induced dissolution of bone-apatite releasing calcium salts and bicarbonate. Hemoglobin releases  $H^+$  after combining with  $O_2$ . In the peripheral capillaries with low  $O_2$  tension and exposure to acid, hemoglobin accepts  $H^+$  and releases  $O_2$ . This controls the pH in the peripheral capillaries despite a high  $PCO_2$ . A reverse of this happens in the lungs with high  $O_2$  partial pressure. The released  $H^+$  in the lungs combines with  $HCO_3^-$  to form  $CO_2$  which gets eliminated with respiration.

The bicarbonate buffer system is the most effective in the extracellular space, where proteins contribute to the intracellular buffering predominantly.

### HENDERSON-HASSELBALCH EQUATION

To understand the respiratory and metabolic components which regulate the systemic pH, it is important to understand the Henderson-Hasselbalch equation:

$$pH = 6.1 + \log \left[ \frac{HCO_3^-}{(0.03 \times PaCO_2)} \right]$$

( $PaCO_2$  measured in mm Hg)

This equation suggests that the ratio of dissolved  $CO_2$  and  $HCO_3^-$  determines the pH. In other words, with primary problem being alterations in  $HCO_3^-$  or  $CO_2$ , the systemic pH can be regulated

by change in the same direction of the other component ( $\text{HCO}_3^-$  or  $\text{CO}_2$ ). The lungs eliminate or retain  $\text{CO}_2$  as necessary; similarly, kidneys optimize the  $\text{HCO}_3^-$  concentration as per situation. The clinical utility of this equation is that pH can be calculated if  $\text{PCO}_2$  and  $\text{HCO}_3^-$  concentrations are known. However, this equation is somewhat difficult for routine use; therefore to have an insight in the acid-base disorder, the equation can be interpreted as the following relationship:

$$\text{pH} \propto \text{HCO}_3^- / \text{PCO}_2$$

This relationship suggests that pH is positively related to  $\text{HCO}_3^-$ , and inversely related to  $\text{PCO}_2$ .

## Respiratory Regulation

The lungs participate in regulating pH by increasing or decreasing the elimination of  $\text{CO}_2$ . The respiratory compensation begins almost immediately within minutes and is fully established by 24 hours. Peripheral chemoreceptors respond to changes in pH,  $\text{PCO}_2$ , and  $\text{PO}_2$ , whereas central chemoreceptors respond only to  $\text{PCO}_2$ . With acidosis, pH changes around the brainstem stimulate hyperventilation, and the reverse is observed with alkalosis. However, the respiratory compensation is not completely effective in restoring pH as only volatile acids, i.e.,  $\text{CO}_2$  can be taken care of by the lungs.

## Renal Regulation

Kidneys are involved in the removal of nonvolatile acids/bases through several active transport systems in the tubules. Kidneys regulate the serum bicarbonate concentration by controlling  $\text{H}^+$  excretion, regulating bicarbonate reabsorption and generation of new bicarbonate. Renal compensation is a comparative slow process and may take up to 3–5 days for full compensation. Elimination of  $\text{H}^+$  in the renal tubule is facilitated by  $\text{Na}^+/\text{H}^+$  counter transport.  $\text{H}^+$  combines with  $\text{HCO}_3^-$  forming  $\text{CO}_2$  and water, where  $\text{CO}_2$  diffuses back into the tubular cell. Close to 85% of filtered bicarbonate is reabsorbed in the proximal tubule through these mechanisms for  $\text{H}^+$  secretion. Apart from this mechanism, secreted  $\text{H}^+$  is also excreted in combination with phosphate ( $\text{HPO}_4^{2-}$ ,  $\text{H}_2\text{PO}_4^-$ ) and ammonia (forming  $\text{NH}_4^+$ ). In this way, kidneys are able to excrete the nonvolatile or fixed acids, amounting to around 1 mmol/kg/day, generated in the body from various sources. Measurement of the amount of  $\text{H}^+$  excreted in the urine can be done by calculating the amount of alkali needed to neutralize the urine, referred to as *titratable acidity*. Normally urine pH is around 6.0 because of  $\text{H}^+$  and ammonium ions.

## ARTERIAL BLOOD GAS ANALYSIS

### Sample Collection

Radial artery is the preferred artery for arterial blood gas (ABG) because of its superficial location and ease of assessment of the collateral circulation. Other alternatives include posterior tibial, dorsalis pedis and femoral artery. Nondominant hand is selected for the radial/ulnar artery puncture. Umbilical artery can be utilized in the first week of life in neonates.

Modified Allen's test must be performed to assess collateral circulation. With the child's hand held high and fist clenched, both radial and ulnar arteries are compressed by the examiner. Once the fist appears blanched, the hand is lowered and pressure is released over the ulnar artery. Return of pink color of the hand within 6 seconds suggests a patent superficial palmar arch.

### General Precautions

- Prolonged storage of the sample (beyond 15 minutes at room temperature or 1 hour at  $4^\circ\text{C}$ ) underestimates  $\text{PO}_2$  especially in hyperleukocytosis, polycythemia, and thrombocytosis. If delay

is inevitable, sample should be kept at  $4^\circ\text{C}$  (not on ice!). With prolonged storage ongoing metabolism in RBCs reduces pH and  $\text{PO}_2$ , whereas  $\text{PCO}_2$  rises.

- Presence of air bubbles in the sample (especially if their volume exceeds 1% of the sample) underestimates  $\text{PCO}_2$ . Bubbles if any should be expelled immediately after sampling.
- Too much heparin may dilute the sample and measured values may be falsely low.
- *Temperature correction* With decrease in temperature,  $\text{PCO}_2$  decreases and pH increases. This is especially important in interpreting blood gases in a hypothermic child.
- Ensure proper mixing of the sample prior to analysis. The syringe should be rolled between the fingers and inverted many times to ensure proper mixing. This two-dimensional movement ensures proper mixing.
- While drawing sample from an arterial catheter, aspirate at least three to four times the volume of the dead space of the catheter before withdrawing ABG sample in another syringe. The aspirated blood can be pushed back into the catheter after sampling.
- Hemolysis of blood may lead to errors in measurement of electrolytes.

## Arterial Blood Gas Analyzer

Automated ABG analyzers have a complex electronic circuitry, electrolyte solutions to promote chemical reaction and electric current, and electrodes (pH,  $\text{PCO}_2$ , and  $\text{PO}_2$ ). pH is measured by determining the potential difference between the measuring electrode and the reference electrode. The  $\text{PCO}_2$  electrode (*Severinghaus electrode*) is a modification of the pH electrode.  $\text{CO}_2$  diffuses across a gas-permeable membrane to a bicarbonate solution and enters a chemical reaction to generate  $\text{H}^+$ . The change in pH is measured indirectly indicating  $\text{PCO}_2$ .  $\text{PO}_2$  is measured by the Clark electrode. Oxygen diffuses across a semipermeable membrane and gets reduced at the cathode generating a current which is proportional to  $\text{PO}_2$ . To ensure appropriate functioning of the analyzer, frequent calibration as recommended by the manufacturer should be performed.

In the routine blood gas analysis, pH,  $\text{PCO}_2$ , and  $\text{PO}_2$  are measured values, whereas rest are calculated values. It is therefore important to measure the electrolyte panel simultaneously which will provide the measured electrolytes needed to calculate anion gap (AG).

Common terms routinely used in blood gas reports are defined in **Box 1**.

## NORMAL BLOOD GAS VALUES

**Table 1** provides the normal blood gas values for arterial and mixed venous blood.

## Interpretation of Blood Gases

There are four major methods of identifying the acid-base disorders: the physiological approach, the base excess approach, the physicochemical approach (Stewart method), and nomograms. Physiological method utilizes the interpretation of pH,  $\text{PCO}_2$  and  $\text{HCO}_3^-$  using the Henderson-Hasselbalch method. Base excess approach is simple but less accurate. Stewart method utilizes the concepts of strong ions and weak acids in calculating strong-ion difference. Siggaard Anderson nomogram relates  $\text{PaCO}_2$  and pH to base excess. We will discuss the widely used and comprehensive physiological approach to interpret blood gases.

### Step 1: Is the pH acidic or alkalotic?

However, acidosis or alkalosis may even be present with a normal pH (i.e., in mixed disorders).

**BOX 1 Terminology in measurement of arterial blood gas**

- **pH:** pH is the negative logarithm of  $H^+$  concentration.
- **$PCO_2$ :**  $PCO_2$  is the partial pressure of  $CO_2$  in blood.
- **$PO_2$ :**  $PO_2$  is the partial pressure of  $O_2$  in blood.
- **Standard pH:** Standard pH is the pH adjusted for temperature of  $37^\circ C$  and  $CO_2$  of 40 mm Hg, that is, it purely reflects  $H^+$  concentration due to the metabolic derangements.
- **Actual bicarbonate (ABC):** Actual bicarbonate is the concentration of bicarbonate in the plasma which is calculated from measurements of  $PCO_2$  and pH.  $PCO_2$  falls by about 4.5% and pH rises by around 0.015 per  $^\circ C$  fall in temperature.
- **Standard bicarbonate (SBC):** Standard bicarbonate is defined as the bicarbonate concentration under standard conditions (temperature  $37^\circ C$ ,  $PCO_2$  40 mm Hg, saturated with oxygen). Hence, it reflects the change in  $HCO_3^-$  due to a nonrespiratory disorder. With respiratory acidosis, ABC is more than SBC, and converse in respiratory alkalosis.
- **Buffer base (BB):** Buffer base is defined as the total buffer capacity of the blood which includes bicarbonate, hemoglobin, plasma proteins and phosphate. Normal range is  $48 \pm 2$  mmol/L. This is estimated by the blood gas analyzer. It is important to feed in the hemoglobin value of the patient into the machine.
- **Actual base excess (ABE):** Actual base excess is defined as the concentration of titratable base when the blood is titrated with a strong acid or base to a plasma pH of 7.40,  $PCO_2$  of 40 mm Hg and  $37^\circ C$  at actual oxygen saturation. ABE is the deviation of the buffer base amount from the normal level. The normal range of base excess or base deficit is between +2 and -2. ABG analyzers calculate BE based on formulas including pH and  $HCO_3^-$  or pH and  $PCO_2$ . A positive base excess (above 2) suggests metabolic alkalosis, whereas negative base excess (below 2) suggests metabolic acidosis.
- **Standard base excess (SBE):** Standard base excess is a reflection of the base excess in the total ECF, of which blood represents approximately one-third. In a way, it is an in vivo expression of base excess. SBE is independent of the  $PCO_2$  and an indicator of the metabolic components in acid-base balance. Normal levels of SBC and SBE base excess excludes metabolic acid-base disorder, whereas an elevated SBC concentration and positive base excess indicates metabolic alkalosis.
- **Total  $CO_2$ :** Total  $CO_2$  value reflects  $CO_2$  in all forms present in the blood, i.e., sum of  $HCO_3^-$ ,  $H_2CO_3$ , carbonate, dissolved  $CO_2$ , and  $CO_2$  bound to amino acids.  $HCO_3^-$  constitutes nearly 95% of the total  $CO_2$ ; hence,  $tCO_2$  is nearly 2 mmol/L higher than  $HCO_3^-$ .

**Table 1** Normal blood gas values

Value	Arterial blood	Mixed venous
pH	7.40 (7.35–7.45)	7.36 (7.31–7.41)
$PO_2$	80–100 mm Hg	35–40 mm Hg
$O_2$ saturation	95%	70–75%
$PCO_2$	35–45 mm Hg	41–51 mm Hg
$HCO_3^-$	22–26 mEq/L	22–26 mEq/L
Base excess	-2 to +2	-2 to +2

**Step 2: Is the primary abnormality respiratory, metabolic or both?**

In primary respiratory disorders, change in pH and  $PCO_2$  is in opposite direction, whereas in primary metabolic disorders, change in pH and  $PCO_2$  is in same direction.

**Acidosis (pH < 7.35) with:**

- **Low  $PCO_2$  ( $PCO_2 < 35$  mm Hg):** Metabolic acidosis with respiratory compensation (respiratory alkalosis)
- **Normal  $PCO_2$ :** Uncompensated metabolic acidosis (uncommon)
- **High  $PCO_2$  ( $PCO_2 > 45$  mm Hg):** Primary respiratory acidosis

**Alkalosis (pH > 7.45) with:**

- **Low  $PCO_2$  ( $PCO_2 < 35$  mm Hg):** Primary respiratory alkalosis
- **Normal  $PCO_2$ :** Uncompensated metabolic alkalosis
- **High  $PCO_2$  ( $PCO_2 > 45$  mm Hg):** Primary metabolic alkalosis with respiratory compensation.

**Step 3: Assessment of hypoxemia and measures of oxygenation**

Assessment of oxygenation relative to ventilation may help in distinguishing respiratory from nonrespiratory causes of acid-base imbalance.

**Step 4: Calculate the AG and adjust the AG for hypoalbuminemia**

$$\text{Anion gap} = Na^+ - (HCO_3^- + Cl^-)$$

Normal AG is between 8 mEq/L and 14 mEq/L. Increased AG is usually associated with metabolic acidosis. There are a few causes of normal AG metabolic acidosis; these are discussed in the following chapter. The anion gap is influenced by the albumin concentration; so, in hypoalbuminemia, the AG has to be adjusted.

$$\text{Adjusted AG in hypoalbuminemia} = \text{observed AG} +$$

$$[2.5 \times (\text{normal albumin} - \text{observed albumin})]$$

**Step 5: What is the extent of compensation?**

Compensation usually does not normalize the pH. Respiratory compensation of metabolic disorders is usually rapid (within minutes to hours), but metabolic compensation of respiratory disorders take longer (hours to days). Extent of compensation depends on the duration of the underlying disorder (acute or chronic). Calculation of the expected compensation is also important to identify mixed acid-base disorder. **Table 2** depicts the extent of compensation in various disorders.

**Step 6: Calculate delta/delta or delta gap**

The ratio of change in anion gap to the change in bicarbonate ( $\Delta AG / \Delta HCO_3^-$ ) helps in assessing the contribution of process causing AG to the actual acidosis.

$$\text{Delta/delta} = (\text{Measured AG} - 12) / (24 - \text{measured bicarbonate})$$

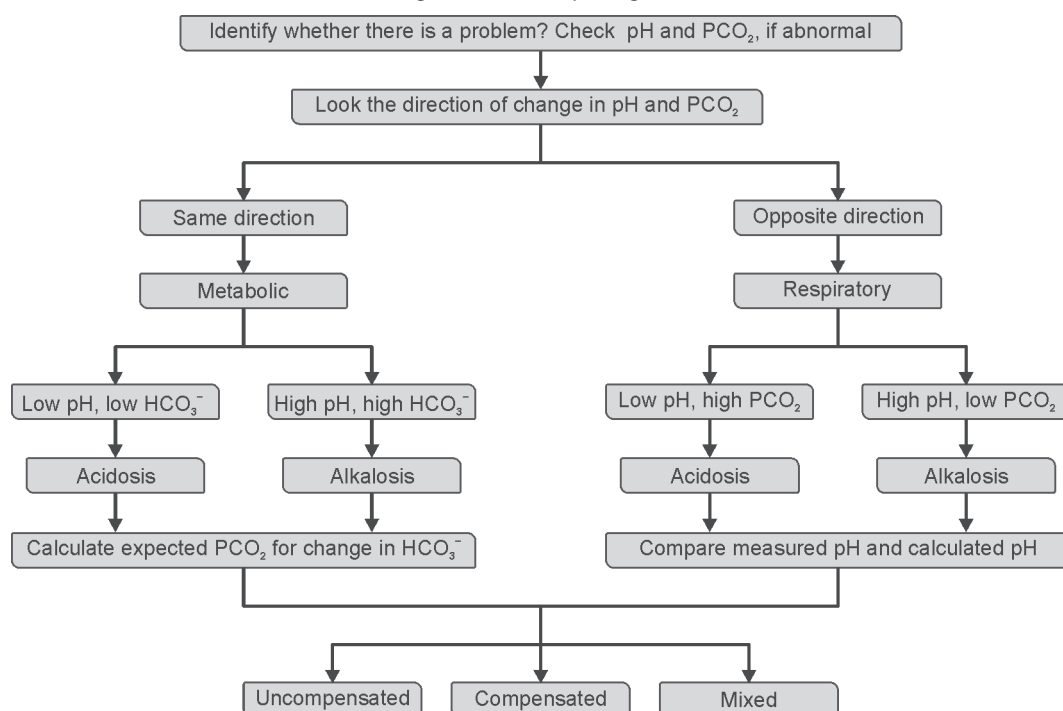

The ratio is usually around 1 if an uncomplicated metabolic acidosis is present. For every one unit increase in AG, the bicarbonate should decrease by 1 mmol/L, keeping the ratio at 1. If the change in the AG is more than the change in the serum bicarbonate, concomitant metabolic alkalosis is also likely to be present. Similarly, if the change in the AG is less than the change in the serum bicarbonate, a concomitant non-AG metabolic acidosis is also likely to be present.

The other parameter is delta gap. When an increased AG metabolic acidosis is present,  $\Delta AG - \Delta HCO_3^-$  is used to screen for mixed disorders. If  $\Delta AG - \Delta HCO_3^- \geq 6$  additional normal AG

**Table 2** Expected compensation in various acid-base disorders

Abnormality	Compensation
Metabolic acidosis	$PCO_2$ decreases due to hyperventilation (respiratory compensation) Expected $PCO_2 = 1.5 \times [HCO_3^-] + 8 \pm 2$
Respiratory acidosis	Acute: $HCO_3^-$ increases by 1 mmol/L for every 10 mm Hg increase in $PCO_2$ Chronic: $HCO_3^-$ increases by 3.5 mmol/L for every 10 mm Hg increase in $PCO_2$
Metabolic alkalosis	$PCO_2$ increases by 7 mm Hg for every 10 mmol/L increase in $HCO_3^-$
Respiratory alkalosis	Acute: $HCO_3^-$ decreases by 2 mmol/L for every 10 mm Hg decrease in $PCO_2$ Chronic: $HCO_3^-$ decreases by 4 mmol/L for every 10 mm Hg decrease in $PCO_2$

**Flow chart 1** Algorithm for interpreting acid-base disorder

(hyperchloremic) metabolic acidosis is present. On the other hand, if  $\Delta AG - \Delta HCO_3^- \leq -6$ , additional metabolic alkalosis is present.

#### Step 7: Identify the cause for the acid-base disorder

A good history and examination is important to understand the likely underlying physiological disturbance which helps in interpreting the blood gas disorder. If the clinical setting does not correlate with the acid-base disorder, errors in ABG analysis must be considered. A thorough assessment of the respiratory, neurological, and renal status is necessary to understand the extent of compensation in blood gases.

**Flow chart 1** gives an algorithmic approach to identify and interpret acid-base disorder.

### IN A NUTSHELL

1. Lungs are responsible for the disposal of volatile acids, whereas kidneys eliminate the nonvolatile acids from the body.
2. Increase in  $CO_2$  concentration in blood causes displacement of oxygen from the hemoglobin (Bohr's effect), and binding of oxygen to hemoglobin in the pulmonary capillaries augments  $CO_2$  unloading (Haldane effect).
3. Kidneys regulate the serum bicarbonate concentration by controlling  $H^+$  excretion, regulating bicarbonate reabsorption and generation of new bicarbonate.
4. Errors in ABG measurements can be avoided by keeping in mind general precautions.
5. In the routine blood gas analysis, pH,  $PCO_2$ , and  $PO_2$  are measured values, whereas rest are calculated values.
6. The assessment of the type of acid-base imbalance and the presence of a mixed acid-base disorder can be done by measurement of  $pCO_2$ , serum bicarbonate, and calculation of the AG.
7. Compensation usually doesn't normalize the pH. Respiratory compensation of metabolic disorders is usually rapid (within minutes to hours), but metabolic compensation of respiratory disorders takes longer (hours to days).
8. Mixed acid-base disorders can present with normal pH.
9. Assessment of oxygenation relative to ventilation may help in distinguishing respiratory from nonrespiratory causes of acid-base imbalance.
10. The ratio of change in AG to the change in bicarbonate ( $\Delta AG/\Delta HCO_3^-$ ) helps in assessing the contribution of process causing AG to the actual acidosis.

## Chapter 5.4

# Abnormalities of Acid-Base Balance

*Dinesh Raj, Rakesh Lodha*

Acid-base abnormalities are common in sick children. Timely recognition of the abnormalities and their causes can be lifesaving. In the respiratory disorders, the primary change is in  $\text{PCO}_2$ ; while in metabolic disorders, the bicarbonate ( $\text{HCO}_3^-$ ) concentrations are primarily affected. So, overall there are four simple acid-base disorders: metabolic acidosis, respiratory acidosis, metabolic alkalosis, and respiratory alkalosis. Mixed acid-base disorders have independently coexisting disorders, apart from the expected physiologic compensatory responses. This chapter reviews the pathophysiology, etiology and brief management of these various acid-base disorders.

## RESPIRATORY ACIDOSIS

Respiratory acidosis is characterized by an increase in  $\text{PaCO}_2$  and a decrease in pH. It can be either acute or chronic.

### Etiopathogenesis

Accumulation of  $\text{CO}_2$  can result from increased production or abnormalities in washing out  $\text{CO}_2$ ; the latter is usually the cause. Respiratory acidosis can be caused by hypoventilation due to decreased respiratory drive or respiratory muscle fatigue; these lead to a generalized fall in alveolar ventilation (**Table 1**). Severe lung diseases associated with ventilation-perfusion mismatch (pneumonia, pulmonary edema or ARDS), airway obstruction (foreign body, asthma or bronchiolitis) or diffusion abnormalities cause hypercarbia due to an imbalance between ventilation and perfusion. Excessive  $\text{CO}_2$  production, as in malignant hyperthermia, is a rare cause of respiratory acidosis.

Acute compensation of respiratory acidosis begins within a few hours with a rise in plasma bicarbonate by 1 mmol/L for every 10 mm Hg increase in  $\text{PCO}_2$ . This early response is due to the acid titration of nonbicarbonate buffers (hemoglobin, intracellular proteins, phosphate and plasma proteins). Chronic compensation is usually complete within 3–5 days with adaptive increase in renal acidification leading to new bicarbonate generation; for every 10 mm Hg increase in  $\text{PCO}_2$ , plasma bicarbonate increases by 3–4 mmol/L (up to a maximum of 38 mmol/L).

The various causes of respiratory acidosis are tabulated in **Table 1**.

### Clinical Features

The clinical features of respiratory acidosis are usually those of the underlying cause. Children with respiratory acidosis due to hypoventilation resulting from central nervous system depression or respiratory muscle fatigue and respiratory failure will have bradypnea, hypoxia and altered sensorium. On the other hand, child with respiratory acidosis due to pulmonary or airway obstruction manifests with tachycardia, tachypnea, respiratory difficulty and features of hypoxia.

Severe acute respiratory acidosis may lead to symptoms of restlessness, anxiety, headache, blurred vision and excessive sweating. Excessive  $\text{CO}_2$  retention may lead to  $\text{CO}_2$  narcosis as manifested by drowsiness, headache, confusion, hallucinations,

**Table 1** Causes of respiratory acidosis

Decreased respiratory drive	Drugs (anesthesia, sedatives) Head trauma Stroke Encephalitis Sleep-disordered breathing Hypothyroidism
Neuromuscular problems	Guillain-Barre syndrome Spinal cord injury Myasthenia gravis Poisonings causing neuromuscular blockade (curare, organophosphate) Myopathies and muscular dystrophies Diaphragmatic palsy
Severe lung disease	Severe pneumonia Acute respiratory distress syndrome Pulmonary edema Lung collapse Interstitial pneumonia Infiltrative disorders
Airway obstruction	Laryngospasm Angioedema Obstructive sleep apnea Foreign body Severe asthma Bronchiolitis
Miscellaneous	Flail chest Pneumothorax Hemothorax Massive ascites Obesity Kyphoscoliosis Permissive hypercapnia

stupor, and even coma. There may be features of raised intracranial pressure. The symptoms are more evident in acute respiratory acidosis compared to chronic respiratory acidosis.

Severe acidosis may also lead to significant vasodilatation and hypotension. With a significant fall in arterial pH, impairment in cardiac function, altered response to catecholamine and cardiac arrhythmia can also occur similar to metabolic acidosis. Rise in serum potassium is uncommon in children with respiratory acidosis as compared to those with metabolic acidosis.

### Diagnosis

The presence of acidemia and elevated  $\text{PCO}_2$  is diagnostic of respiratory acidosis. An accurate history and good examination are essential to help determine whether it is acute or chronic. It is essential to remember the expected compensations in acute and chronic respiratory acidosis to determine presence of mixed metabolic and respiratory abnormalities. Calculation of alveolar arterial oxygen gradient  $[(A-a) \text{DO}_2]$  can assist in determining the etiology. It is usually increased in patients with intrinsic pulmonary disease. A normal gradient usually excludes pulmonary disease and indicates central alveolar hypoventilation or abnormalities of chest wall or muscles of breathing.

### Treatment

Treatment of respiratory acidosis usually depends on the severity of the abnormality and the rapidity of development. Rapidly developing severe acidosis may need intubation for optimization of alveolar ventilation. Treatment of the underlying cause is the mainstay of management. Respiratory acidosis in a ventilated

child should warrant assessment of tracheal tube displacement or obstruction, air leaks, worsening of the lung/airway disease and/or ventilator malfunction. In the absence of these, a change in ventilator settings usually facilitates CO<sub>2</sub> removal.

As increased PCO<sub>2</sub> is associated with cerebral vasodilatation and increase in intracranial pressure. Children with CNS disorders especially meningoencephalitis, benefit with mechanical ventilation. Invasive mechanical ventilation should be avoided as far as possible in children with chronic respiratory acidosis. Measures to improve lung function usually result in improvement in respiratory acidosis. Ventilation of such patients should be cautious as rapid reduction in PCO<sub>2</sub> may lead to sudden elevation in pH which can be life-threatening. Such patients also tolerate extubation poorly with increasing acidosis in the absence of metabolic compensation. As these patients are poorly responsive to hypercarbia, and more sensitive to hypoxemia, the lowest possible FiO<sub>2</sub> to maintain adequate oxygenation is recommended. A high FiO<sub>2</sub> may decrease the respiratory drive, increasing the acidosis further.

## RESPIRATORY ALKALOSIS

Respiratory alkalosis is characterized by decrease in PCO<sub>2</sub> and an increase in pH.

### Etiopathogenesis

The causes of respiratory alkalosis include increased CO<sub>2</sub> elimination (hyperventilation) or uncommonly decreased CO<sub>2</sub> production. Respiratory alkalosis is often seen in mechanically ventilated children in the pediatric critical care setting. The various causes of respiratory alkalosis are summarized in **Table 2**. Hyperventilation often occurs as a response to hypoxemia via the peripheral chemoreceptors. Lung pathology may cause respiratory

alkalosis by stimulation of chemoreceptors or mechanoreceptors in the lung.

The immediate compensatory response to decrease in CO<sub>2</sub> is an acute decrease in plasma bicarbonate mediated by alkaline titration of nonbicarbonate buffers. Renal adaptation accounts for the further reduction in bicarbonate levels attributed to reduction in renal ammonium and titratable acid secretion and decrease in filtered bicarbonate reabsorption. For every 10 mm Hg decrease in PCO<sub>2</sub>, acute compensation reduces bicarbonate levels by 2 mmol/L, whereas chronic compensation (occurs over 2-3 days) reduces bicarbonate concentrations by 4 mmol/L.

### Clinical Features

Acute respiratory alkalosis is more often symptomatic than chronic respiratory alkalosis. The symptoms are secondary to decreased cerebral perfusion including light-headedness, confusion, and seizures. As respiratory alkalosis may lead to hypocalcemia due to decrease in ionic calcium, some of the symptoms attributed to hypocalcemia may be observed. They include perioral numbness, tetany, paresthesias, and laryngeal spasm. Uncommonly, cardiac arrhythmias may be observed.

### Treatment

Treatment is usually directed toward the underlying disorder. Chronic respiratory alkalosis is often asymptomatic, and treatment is usually not required. Rapid assessment of the cause of acute respiratory alkalosis should be made to reduce the acute symptoms. In case of anxiety or psychogenic hyperventilation, reassurance or rebreathing into a paper bag may help in increasing PaCO<sub>2</sub>. Children on mechanical ventilation benefit with reduction in rates, tidal volume or inspiratory pressures.

## METABOLIC ACIDOSIS

Metabolic acidosis is characterized by low systemic pH along with low bicarbonate concentration. An associated decrease in PCO<sub>2</sub> is observed due to respiratory compensation. Low PCO<sub>2</sub> may sometimes not be found in case of a mixed acid-base disorder with concurrent respiratory acidosis.

### Anion Gap

A calculation of anion gap helps in further characterizing the underlying problem leading to metabolic acidosis. The concept of anion gap rests on the fact that to maintain electrical neutrality in the blood, the total number of cations and anions must be equal. As the concentration of minor anions and cations does not change much, so anion gap can be described as the difference of major cations and major anions as follows:

$$\text{Anion gap} = \text{Na}^+ - [\text{Cl}^- + \text{HCO}_3^-]$$

Anion gap is hence the difference of unmeasured cations and unmeasured anions. The normal anion gap is 8-14, but can be up to 16 in sick neonates. With modern analyzers using ion specific electrodes estimating chloride levels very accurately, the anion gap could actually be low at  $6 \pm 3$ . Therefore, analyzer manufacturer's reference range should be kept in mind before interpreting anion gap. A major contribution to the anion gap is by serum albumin. Therefore, in certain situations with low albumin (nephrotic syndrome, liver failure, and malnutrition), the anion gap is low. Hypoalbuminemia can therefore mask the increase in anion gap needing a correction for the level of hypoalbuminemia. For every 1 g/dL decrease in albumin, anion gap decreases by 2.5.

Miscellaneous	Drugs: Progesterone, salicylates, catecholamines Sepsis Hepatic failure Mechanical ventilation

## Etiopathogenesis

With loss of bicarbonate, pH decreases due to increase in  $H^+$ . If the anion accompanying  $H^+$  is chloride, then serum chloride levels increase matching bicarbonate, keeping the anion gap normal. This type of acidosis is known as *normal anion gap metabolic acidosis*. However, if the anion accompanying  $H^+$  is other than chloride, chloride levels remain normal and anion gap increases. The increased unmeasured anions balance the fall in bicarbonate. This type of acidosis is known as *increased anion gap metabolic acidosis*.

The normal anion gap metabolic acidosis could be either of renal origin (renal tubular acidosis) or extrarenal origin (diarrhea, chloride excess due to parenteral fluids). A commonly used mnemonic for increased anion gap metabolic acidosis is MUDPILES (Methanol; Uremia [renal failure]; Diabetic or starvation ketoacidosis; Paracetamol or Propylene glycol; Iron or Inborn error of metabolism; Lactic acidosis; Ethylene glycol; Salicylates).

Even in the setting of a normal pH and bicarbonate, a significantly elevated anion gap (above 20) is strongly suggestive of metabolic acidosis.

### Normal Anion Gap Metabolic Acidosis (Table 3)

To compensate for the bicarbonate loss, new bicarbonate generation resulting from net acid excretion in the form of ammonium ion is performed by the kidney. A useful method for evaluation of normal anion gap metabolic acidosis is assessment of urinary ammonia excretion. As direct measurement of urinary ammonia is not routinely available, indirect evidence can be obtained by calculation of urinary anion gap (UAG).

$$UAG = (U_{Na^+} + U_{K^+}) - U_{Cl^-}$$

UAG can be either positive or negative depending on urinary ammonia excretion. Negative UAG suggests presence of an unmeasured cation (usually  $NH_4^+$ ) in the urine. Whereas positive UAG is observed in renal tubular acidosis, renal failure, and hypoaldosteronism due to impaired urinary ammonia excretion. More than the magnitude of UAG, the direction of UAG (positive or negative) is of more clinical relevance. However, in certain scenarios UAG is not reliable. These include urine pH above 6.5, presence of polyuria, excretion of urinary ammonium with anions other than chloride (such as ketoacids, salicylates, D-lactate, and penicillins).

*Diarrhea* is commonly associated with normal anion gap metabolic acidosis. The diarrheal losses are usually rich in bicarbonate leading to metabolic acidosis. The volume depletion accompanying diarrhea increases renal NaCl reabsorption causing hyperchloremic metabolic acidosis with a normal anion gap. In response to acidosis, kidneys increase net acid excretion in the form of urinary ammonium.

*Proximal renal tubular acidosis* (Type 2 RTA) is characterized with decreased ability to reabsorb filtered bicarbonate. More commonly it presents as a diffuse proximal tubular dysfunction with impaired reabsorption of glucose, amino acids, phosphate, uric acid, and low molecular weight proteins. As distal acidification is intact in proximal RTA, children are able to acidify urine and urine pH is below 5.5. Some medications (trimethoprim-sulfamethoxazole, topiramate, spironolactone, and cyclosporine) can impact the kidneys and present with normal anion gap acidosis.

Children with *distal RTA* (Type 1) are unable to acidify urine and urine pH is above 5.5. The underlying problem could be reduced  $H^+$  secretion (secretory defect) in distal tubule or back-leak of protons (gradient defect) due to an abnormally permeable

distal tubule. Amphotericin B can also present as a distal RTA physiology by increasing the back-leak of protons.

*Glue sniffing* is an uncommon cause of acquired distal RTA. The fumes contain toluene which inhibits  $H^+$  secretion in collecting ducts. Metabolism of toluene leads to formation of hippuric acid and benzoic acid. With normal blood volume and urine output, these are eliminated in the urine and a normal anion gap metabolic acidosis is observed. In volume depleted state, urinary elimination is restricted and an increased anion gap is observed.

### Increased Anion Gap Metabolic Acidosis (Table 3)

Increased anion gap metabolic acidosis suggests the addition of an acid to the blood. This could be either secondary to increased production or decreased elimination of an endogenously produced acid (lactic acidosis, renal failure) or due to presence of an exogenous acid in the blood (as in poisoning).

*Lactic acidosis* is one of the commonest causes of increased anion gap metabolic acidosis. Most often it is due to tissue hypoxia causing anaerobic metabolism and excess formation of lactate. The cause underlying tissue hypoxia usually include shock (septic, cardiogenic, or hemorrhagic), severe anemia, hypoxemia (respiratory distress due to any cause), and carbon monoxide poisoning. A small amount of lactate normally produced by the body is metabolized by the liver. However, in some cases the excessive amounts produced in the body overwhelms the capacity of liver to metabolize. Once the underlying problem resolves, lactate is metabolized and converted in bicarbonate thereby normalizing the pH. Sometimes, lactic acidosis occurs without tissue hypoxia (as in inborn errors of metabolism, poisonings and liver failure).

*Diabetic ketoacidosis* is another common cause of increased anion gap metabolic acidosis. The excessive production of ketone bodies, i.e.,  $\beta$ -hydroxybutyrate and acetoacetate attribute to the unmeasured anions in the anion gap. A simultaneous presence of increased anion gap acidosis and hyperglycemia should suggest this diagnosis. As routine urine dip sticks for ketoacids detects acetone and acetoacetate but not  $\beta$ -hydroxybutyrate, this diagnosis is sometimes missed early on as the predominant ketoacid is  $\beta$ -hydroxybutyrate. With treatment, acetoacetate increases and the

**Table 3** Metabolic acidosis: causes

<i>Normal anion gap (hyperchloremic) metabolic acidosis</i>	<i>Increased anion gap metabolic acidosis</i>

	<i>Advanced renal failure</i>

strip test becomes strongly positive. Other causes of ketoacidosis include starvation, prolonged fasting and alcohol use.

*D-lactic acidosis* is an uncommon form of metabolic acidosis which occurs in children with small bowel syndrome with bacterial overgrowth. In these children, carbohydrates which normally get absorbed in the small intestine reach the colon in large amounts and get fermented by intestinal bacteria releasing D-lactic acidosis. The typical presentation is presence of neurological symptoms (in the form of confusion, slurred speech, and ataxia) after a carbohydrate rich meal. Serum lactate levels are fallaciously normal as the laboratory assays estimate the L-enantiomer. Supportive care, antibiotics, and low carbohydrate therapy is usually sufficient.

*Toxic ingestions* are frequent causes of increased anion gap metabolic acidosis. These include iron, paracetamol, salicylates, metformin, ibuprofen, methanol, ethylene glycol, toluene, paraldehyde and propylene glycol. Iatrogenic propylene glycol toxicity is observed in patients receiving large doses of intravenous benzodiazepines (as in lorazepam) which contain propylene glycol as solvent. Toxic alcohol ingestions can be identified by calculating the serum osmolar gap which is the difference between measured and calculated serum osmolality. As alcohols are osmotically active, an osmolar gap of above 20 mOsm is suggestive of toxic alcohol ingestion.

*Advanced renal failure* causes an increased anion gap acidosis due to decreased ability of urinary acidification and undersecretion of ammonium ion.

## Clinical Features

The clinical features of the underlying disorder causing metabolic acidosis are more prominent. The clinical manifestations due to metabolic acidosis depend on the severity of the acidosis and the respiratory function. Mild metabolic acidosis with appropriate respiratory compensation is characterized by rapid and deep breathing (Kussmaul respiration). Fall in blood pH below 7.2 may be associated with myocardial dysfunction with impaired contractility; the risk of ventricular arrhythmias increases if pH is less than 7.1. Severe acidosis attenuates the response to catecholamines. In neonates, metabolic acidosis can cause pulmonary vasoconstriction which aggravates persistent pulmonary hypertension.

Neurological symptoms, varying from lethargy to coma have been described in metabolic acidosis. Chronic acidemia, as with renal failure and renal tubular acidosis, can result in skeletal problems due to release of calcium ions and phosphate during bone buffering of the excess  $H^+$  ions; this contributes to impaired growth. Other metabolic impairments that may occur with metabolic acidosis are hyperkalemia, insulin resistance, increased protein catabolism and reduced ATP synthesis that are seen more commonly with long standing metabolic acidosis.

## Treatment

Though in most conditions, correction of the acidemia can be achieved by  $NaHCO_3$  infusion, it is more important to correct the underlying disorder. The initial therapeutic goal in patients with severe acidemia is to raise the systemic pH to above 7.0–7.1, a level at which arrhythmias become less likely. At this pH, the cardiac contractility and responsiveness to catecholamines is likely to be restored. Intravenous administration of sodium bicarbonate is indicated only in patients with severe metabolic acidosis; this should be done only if ventilation is adequate. Exogenous sodium bicarbonate is usually not required if the initial arterial pH is greater than 7.10, the child is asymptomatic and the underlying

process can be controlled. The amount of bicarbonate ( $HCO_3^-$ ) required to correct the acidemia can be estimated by the formula:

$$HCO_3^- \text{ required} = 0.6 \times \text{body weight} \times HCO_3^- \text{ deficit per liter.}$$

As the added  $HCO_3^-$  produces a large increase in the plasma  $HCO_3^-$  concentration within a few minutes, measurement of pH shortly after administration of  $HCO_3^-$  may overestimate the final effect of the treatment. Alkali therapy is usually not required in lactic acidosis or ketoacidosis where the metabolism of the organic anions will regenerate  $HCO_3^-$ . Similarly, citrate salts of sodium or potassium may be preferable in the chronic treatment of renal tubular acidosis.

Metabolic acidosis due to diarrheal losses should be corrected by expansion of extracellular fluid; in mild cases use of oral rehydration sachets for correction of dehydration suffices, while more severe cases are treated with intravenous Ringer's lactate solution. Correction of the underlying disorder is the primary therapy in lactic acidosis. For example, reversal of circulatory failure will reduce the output of lactate and allow metabolism of lactate to  $HCO_3^-$ . Current evidence does not support routine use of sodium bicarbonate in treatment of lactic acidosis. However, a small amount of sodium bicarbonate may be administered to patients with severe metabolic acidosis to raise the pH to 7.10.

In diabetic ketoacidosis, insulin is the mainstay of therapy. However, sodium bicarbonate therapy may be beneficial if there is marked acidemia (pH < 6.9).

In renal failure, exogenous alkali therapy is not used routinely. Usually in most patients, the arterial pH is maintained close to 7.3 because of respiratory compensation. If child has hypocalcemia, an increase in pH can precipitate tetany. There is also a risk of volume expansion. Sodium bicarbonate therapy may be considered if the plasma  $HCO_3^-$  is less than 12 mEq/L, the patients are symptomatic or there is persistent hyperkalemia. In children, alkali therapy is used more frequently, as acidemia interferes with growth. In renal failure, the alkali of choice is sodium bicarbonate. Citrate may increase aluminum absorption in children receiving aluminum hydroxide.

Sodium bicarbonate administration is helpful in poisoning due to salicylates, tricyclic antidepressant, ethylene glycol and methanol as they help in eliminating the poisonous agent through renal route. Long term sodium bicarbonate therapy may be necessary in cases of inborn error of metabolism.

Dialysis either peritoneal or hemodialysis may be required in treatment of severe metabolic acidosis due to renal failure or poisoning due to methanol or ethylene glycol.

## METABOLIC ALKALOSIS

Metabolic alkalosis is characterized by an increase in the systemic pH along with increased bicarbonate concentration. Hypoventilation occurs as respiratory compensation attempts to bring down pH by increasing  $PCO_2$ . With every 10 mmol/L increase in  $HCO_3^-$ ,  $PCO_2$  increases by 7 mm Hg. As kidneys have enormous capacity to eliminate bicarbonate, accumulation of bicarbonate must be accompanied by a decreased ability to eliminate bicarbonate, so as to sustain metabolic alkalosis.

## Etiopathogenesis

**Table 4** lists the causes of metabolic alkalosis.

Contraction alkalosis (or chloride depletion alkalosis) is the situation in which extracellular fluid contraction caused by chloride losses lead to metabolic alkalosis. The volume contraction in this setting alters the renal handling of electrolytes, bicarbonate

**Table 4** Metabolic alkalosis: causes

Chloride responsive	Chloride resistant
Vomiting	Primary hyperaldosteronism
Nasogastric drainage	Cushing syndrome
Diuretics (Thiazides, metolazone, loop diuretics)	ACTH or renin secreting tumor
Cystic fibrosis	Glucocorticoid remediable aldosteronism
Recovery from chronic hypercapnia	Adrenogenital syndrome
Congenital chloride diarrhea	Fludrocortisone treatment Bartter syndrome Gitelman syndrome Liddle syndrome Severe hypokalemia Severe hypercalcemia Severe hypomagnesemia

and acid excretion. Sodium and bicarbonate excretion increase initially but then decrease rapidly with a concomitant increase in potassium excretion. Hence, hypokalemia is a prominent feature of metabolic alkalosis. Hypokalemia stimulates  $H^+$  secretion and  $NH_4^+$  generation needing to sustain metabolic alkalosis. Chloride depletion affects  $HCO_3^-$  secretion through  $Cl^- - HCO_3^-$  exchanger. With severe hypokalemia, chloride reabsorption is also limited via the  $Na^+ - K^+ - 2Cl^-$  transporter. An understanding of this complex interplay of potassium, chloride, and bicarbonate handling of the kidneys in sustained metabolic alkalosis may help in identifying the likely cause and initiating appropriate therapy.

Broadly metabolic alkalosis can be divided into *chloride responsive* and *chloride resistant metabolic alkalosis*. The causes of *chloride responsive metabolic alkalosis* are persistent vomiting, nasogastric drainage, diuretics administration, recovery from chronic hypercapnia, and congenital chloride diarrhea. With vomiting and continuous nasogastric drainage,  $Cl^-$  and  $H^+$  are lost simultaneously. Hypokalemia occurs both due to gastric potassium losses and renal potassium wasting. A volume and chloride depleted state results, which persists unless resuscitation with chloride containing fluids is done to replenish chloride stores.

Children with *cystic fibrosis* can present with metabolic alkalosis, hypokalemia, and hyponatremia due to excessive losses in sweat. This is more often in hot summer months and occasionally they may be wrongly labelled as pseudo-Bartter syndrome due to such presentation.

An additional condition may be seen in ICU settings. In children with chronic respiratory acidosis, there is increase in the bicarbonate as a compensatory mechanism. If there is a rapid fall in the  $PCO_2$  due to initiation of mechanical ventilation or modification of settings of ventilator, the blood gas analysis will suggest metabolic alkalosis. This situation can easily be diagnosed if the clinical course and serial blood gas analysis reports are evaluated.

Urinary chloride excretion can differentiate between chloride responsive and chloride resistant metabolic alkalosis. A urinary chloride level below 25 mmol/L is suggestive of an appropriate response to alkalosis and indicates volume contraction and non-renal causes. A high urinary chloride (>40 mmol/L)

suggests an inappropriate renal excretion of NaCl probably due to mineralocorticoid excess or severe hypokalemia. A child on diuretics may have a high chloride excretion initially but decreased excretion once the diuretic effect is over. Patient with low urinary chloride respond to saline with improvement of ECF and correction of alkalosis. However, children with high urinary chloride do not benefit with chloride supplementation and continue to lose chloride in urine unless the underlying condition is corrected.

Diuretics (loop or thiazides) cause volume depletion stimulating angiotensin II, aldosterone and adrenergic pathways. Hypokalemia caused by these diuretics increases acid excretion. Enhanced delivery of sodium to distal tubules also facilitates acid excretion. An edematous child who may already be volume depleted is at increased risk of metabolic alkalosis due to diuretics.

The causes of chloride resistant metabolic alkalosis include mineralocorticoid excess, severe hypokalemia, severe hypercalcemia, severe hypomagnesemia, Bartter syndrome, Gitelman syndrome, and Liddle syndrome. Presence of hypertension and metabolic alkalosis suggests mineralocorticoid excess. In a child with normal or low blood pressure and metabolic alkalosis, the Bartter or Gitelman syndrome are likely. Measurements of plasma renin and aldosterone levels are useful in differentiating syndromes of mineralocorticoid excess from those with apparent mineralocorticoid excess. Children with severe  $K^+$  deficiency do not improve despite chloride supplementation, but a small increment in  $K^+$  levels lead to remarkable recovery. Refeeding after starvation may also lead to a sudden rise in  $HCO_3^-$  leading to mild metabolic alkalosis. The possible causes include bicarbonate formed from the metabolism of organic anions, and concomitant deficiency of  $K^+$  and  $Cl^-$ .

## Clinical Features

Mild to moderate metabolic alkalosis is usually asymptomatic. The symptoms of the underlying disorder leading to acid-base imbalance may be predominant. Altered sensorium can occur secondary to cerebral vasoconstriction due to alkalosis. Hypokalemia which usually accompanies metabolic alkalosis may cause cardiac arrhythmias. Hypocalcemia due to decreased ionized calcium may lead to tetany, muscle cramps, seizures and other neurologic manifestations. Polyuria and polydipsia may occur secondary to potassium depletion. Patients on digitalis are on higher risk of arrhythmia in a setting of hypokalemia and metabolic alkalosis.

## Treatment

The aim of treatment of metabolic alkalosis is to correct the volume,  $Cl^-$  and  $K^+$  deficits. Efforts should be directed at correction of the underlying disease/condition. Oral or intravenous administration of sodium chloride and water is indicated in chloride responsive causes of metabolic alkalosis. With the exception of hypotension or shock or severe metabolic derangement, gradual correction is preferable to avoid complications of volume overload. The efficacy of such treatment can be assessed bedside by monitoring the urine pH. Urine pH, which is often below 5.5 before therapy, increases to beyond 7.0 once volume and chloride are replaced.

The administration of saline is usually ineffective in chloride resistant causes of metabolic alkalosis and can worsen hypertension. In patients with edematous states, withholding diuretics is the corrective therapy. Acetazolamide may be used to treat both edema and alkalosis, where withholding diuretics alone does not help. Correction of severe hypokalemia (as in states of mineralocorticoid excess) leads to correction of alkalosis.

### IN A NUTSHELL

1. Respiratory acidosis can be caused by hypoventilation, severe lung disease associated with ventilation-perfusion mismatch, airway obstruction or diffusion abnormalities.
2. Respiratory alkalosis can be caused by either increased CO<sub>2</sub> elimination (hyperventilation) or less commonly decreased CO<sub>2</sub> production.
3. A calculation of anion gap helps in characterizing the underlying problem leading to metabolic acidosis.
4. Causes of normal anion gap metabolic acidosis include diarrhea, renal tubular acidosis, early renal failure and chloride excess.
5. A useful method for evaluation of normal anion gap metabolic acidosis is assessment of urinary ammonia excretion.
6. Causes of increased anion gap acidosis include lactic acidosis, ketoacidosis, poisonings, and advanced renal failure.
7. Causes of chloride responsive metabolic alkalosis are persistent vomiting, nasogastric drainage, diuretics administration, recovery from chronic hypercapnia, and congenital chloride diarrhea.
8. Causes of chloride resistant metabolic alkalosis include mineralocorticoid excess, severe hypokalemia, severe hypercalcemia, severe hypomagnesemia, Bartter syndrome, Gitelman syndrome, and Liddle syndrome.
9. Urinary chloride excretion can differentiate between chloride responsive and chloride resistant metabolic alkalosis.

## Chapter 5.5

# Sodium and Related Disorders

Andrew C Argent, Mignon I McCulloch

Sodium is the dominant ion in the extracellular space and is extremely important in the maintenance of osmotic gradients and electrical neutrality in the body. Normally the human body has a remarkable capacity to deal with large loads of water and/or sodium, but under certain circumstances that capacity is limited and abnormalities of sodium concentrations occur. The renal control of sodium is integral to the understanding of these processes. Dysnatremia (where sodium levels are above or below the normal range) or rapid changes in sodium concentration are relatively common in sick children and both may have profound consequences, with major impact on the brain. There is a growing realization that even relatively mild dysnatremia may be associated with increased morbidity in sick adults.

Pediatricians have been aware of hyponatremia related to inadequate feeding in breastfed neonates or as a complication of gastroenteritis or salt overload. Symptomatic hyponatremia in hospitalized children has been reported in bronchiolitis, pneumonia and meningitis; and following surgery, together with a growing realization that this might have been iatrogenic. More recently, iatrogenic deaths and severe neurological morbidity have been attributed to hyponatremia related to administration of hypotonic fluids to previously normal children in hospital.

## ETIOLOGY

Dysnatremia may be the consequence of a primary illness affecting the child, but is frequently the consequence of inappropriate administration of fluids and electrolytes to sick or injured children.

Hypernatremia is seen most commonly in the setting of acute fluid loss, which may occur in a variety of settings. In preterm infants, hypernatremia may be related to excessive water losses through the skin, particularly in very low birthweight infants who are kept under radiant heaters and/or phototherapy units. Hypernatremia is also seen in breast-fed infants who have been receiving inadequate amounts of breast milk or if formula feeds have been overly concentrated. In older infants, gastroenteritis is the most common cause of hypernatremia, particularly those in whom oral rehydration fluid have been mixed incorrectly with a high concentration of salt.

Hyponatremia develops frequently in hospitalized children, particularly if they are treated with hypotonic intravenous fluids (the higher the proportion of fluids given intravenously, the higher the risk). These fluids can be either as prepackaged *maintenance fluid* solutions or as “*self-mixed*” cocktails of fluids. Particular clinical conditions which are more frequently associated with development of hyponatremia include cardiac diagnosis, pneumonia or respiratory infections, neurological disease or neurosurgical procedures, surgical reason for admission, or an underlying hematology/oncology diagnosis. Recently a number of authors and organizations have concluded that the incidence of hyponatremia could be substantially reduced by the use of intravenous fluids with 0.9% saline and not hypotonic fluids in sick children.

Hyponatremia is seen much less frequently in the context of endocrine abnormalities such as adrenal insufficiency, and more commonly in the context of children who have renal disease (transient acute kidney injury or chronic established disease) and those who have been on diuretic therapy (often in the context of underlying cardiac disease).

## PATHOGENESIS

### Normal Physiology

The concentration of sodium in the body is closely related to the water content of the body. In the infant, total body water constitutes approximately 70% of body weight (approximately 45% in the intracellular compartment, and about 25% in the extracellular compartment) and this changes during normal growth to the adult situation where body water constitutes 50–60% of body water (more in males).

Sodium is distributed throughout the body, with major differences in concentration between the intracellular and extracellular compartments (**Table 1**) and approximately 40% of total body sodium is within bone (in adults). Generally, water can move freely across cell membranes and does so in response to the osmotic pressure differences between the intracellular and extracellular spaces. As the intracellular space includes a wide number of osmotically active substances, the osmotic pressure within the cell is maintained by the active extrusion of sodium from the cell and normally there is little osmotic gradient across the cell membrane. As sodium is the major extracellular ion, significant changes in extracellular sodium may be associated with significant fluid shifts between the intracellular and extracellular spaces. Cells are able to respond in a variety of ways to changes in extracellular osmolality and change the intracellular osmolality. In hyperosmolar situations, they are able to increase the intracellular osmolality by degrading macromolecules such as proteins and glycogen to amino acids and glucose while forming other *osmolytes* such as polyols, methylamines and certain amino acids. The reverse process occurs in hypo-osmolar situations. Unfortunately these processes take time, and thus, rapid changes in electrolyte

**Table 1** Electrolyte concentrations in the body

Electrolyte	Intracellular concentration	Extracellular concentration	Plasma concentration
Sodium (Na <sup>+</sup> )	15 mmol/L	143 mmol/L	141 mmol/L
Potassium (K <sup>+</sup> )	140 mmol/L	4 mmol/L	4 mmol/L
Chloride (Cl <sup>-</sup> )	8 mmol/L	115 mmol/L	103 mmol/L
Calcium (Ca <sup>++</sup> )	0.1 μmol/L	1.3 mmol/L	2.5 mmol/L
Bicarbonate (HCO <sub>3</sub> <sup>-</sup> )	15 mmol/L	28 mmol/L	25 mmol/L
Magnesium (Mg <sup>++</sup> )	15 mmol/L	0.7 mmol/L	1 mmol/L
Phosphate (PO <sub>4</sub> <sup>-</sup> )	10 mmol/L	1 mmol/L	1 mmol/L

concentration (particularly sodium) may cause significant cell damage, particularly within the brain where changes may be exacerbated by thrombosis in the venous structures and by changes in intracranial pressure. These processes are often complicated by administration of various fluids and drugs.

Generally water moves freely through the endothelia between body compartments in response to the balance between oncotic pressures and hydrostatic pressures in those compartments. Fluid shifts between the intravascular and extracellular fluid compartments are largely driven by hydrostatic pressure and oncotic pressure related to macromolecules such as proteins.

Different body fluids have different concentrations of sodium (**Table 2**). Usually gastrointestinal fluids are secreted into the gut and mostly reabsorbed (leaving approximately 30 mmol/L sodium in relatively low volumes of normal stool), particularly in the large intestine. Thus, the normal gastrointestinal losses of sodium are low. However, in situations where there are abnormal gastrointestinal

**Table 2** Sodium concentration in different body fluids

Fluid	Sodium concentration (mmol/L)
<i>Gastrointestinal</i>	
Saliva	80
Gastric	60

losses (vomiting; nasogastric tube drainage; presence of fistulae or stomas; diarrhea) there may be considerable losses of sodium. In gastroenteritis, the sodium losses may be related to specific pathogens with much higher sodium losses in gastroenteritis related to enteropathogenic *E. coli* or *Vibrio cholerae* than in rotavirus diarrhea. It is important to note that insensible fluid losses (from respiration and skin losses) do not contain sodium. While little sodium is generally lost through sweat, this may not be true in patients with cystic fibrosis who may lose significant amounts of sodium through sweat.

In the normal adult kidney, approximately 1.3 kg of sodium chloride (NaCl) is filtered through the glomeruli each day, together with some 180 liters of water. The vast majority of the NaCl and water are reabsorbed in the tubular system and both salt and water levels in the body are tightly regulated by a variety of endocrine systems. The urine output may vary substantially and urinary sodium concentration can vary between less than 1 mmol/L and 300 mmol/L. As a consequence the normal adult has a considerable capacity to deal with a wide range of both water and sodium intake without developing abnormal serum sodium levels. This is not true in premature babies and young infants who have limited renal concentrating capacity.

Water intake and output may vary considerably throughout the day and from day to day. The excretion of sodium and water by the kidney are controlled by the renin-angiotensin system via the adrenal glands (increased angiotensin II production causes the retention of sodium and associated water), the arginine vasopressin system via the posterior pituitary gland (increased secretion increases water retention by the body) and the natriuretic peptides secreted by the brain and the heart (**Flow chart 1**). The arginine vasopressin system may also stimulate thirst with subsequent changes in fluid intake in patient who are able to seek additional fluid and drink.

## Pathophysiology

Dysnatremia may arise in a number of situations (**Table 3**). Changes in the sodium concentrations significantly alter the osmolality of the extracellular fluid compartment, and this may be exacerbated if there are concomitant changes in the glucose concentration (as in diabetes mellitus, or not uncommonly in severe hyponatremia related to gastroenteritis). This change in osmolality may cause fluid shifts between the intracellular and extracellular spaces with subsequent damage, particularly to the brain. In addition, hyponatremic states may be associated with hypercoagulability. Thus, cerebral sinus and venous thrombosis have been associated with hyponatremia in children of all ages. Complications of dysnatremia have been described both in response to the primary

condition, and in response to rapid iatrogenic correction of the dysnatremia.

## Hypernatremia

Hypernatremia may be related to either water loss, sodium overload or a combination of both of these (**Table 3**). Severe hypernatremia in the neonatal period may be a complication of inadequate breast-feeding, of inappropriate mixing of formula feeds or less frequently underlying gastrointestinal problems or renal disease. The condition may have a range of presentations, but may have severe complications including cerebral venous and venous sinus thrombosis with severe long-term neurological consequences.

Hypernatremia in gastroenteritis may be relatively common in developing countries, particularly if there have been errors with the constitution of rehydration fluids. In this setting, the hypernatremia is primarily related to gastrointestinal fluid losses, but may also be exacerbated by renal tubular dysfunction with inadequate urinary concentration. This will only become obvious if urine output is specifically monitored using a urinary catheter.

Hypernatremia is also seen in neurological conditions where it may be the result of diabetes insipidus related to damage to the posterior pituitary, or it may be the consequence of iatrogenic administration of hypertonic saline. Although hypertonic saline has been extensively used to try and reduce brain swelling in neurological or neurosurgical situations, there is evidence that hypernatremia in this setting may be associated with adverse outcomes.

## Hyponatremia

During illness or injury there may be substantial changes in the endocrine environment which generally tend toward retention of water (with or without sodium). Arginine vasopressin levels are frequently elevated in patients with pneumonia and meningitis (including tuberculous meningitis, following surgery or other procedures or following therapy with vasopressin). The elevation of vasopressin may reflect relative hypovolemia or an attempt to improve cerebral perfusion. In some situations administration of a fluid bolus has been shown to cause normalization of the vasopressin levels, but administration of hypotonic fluids—which used to be common clinical practice—to these children will almost invariably result in the development of hyponatremia.

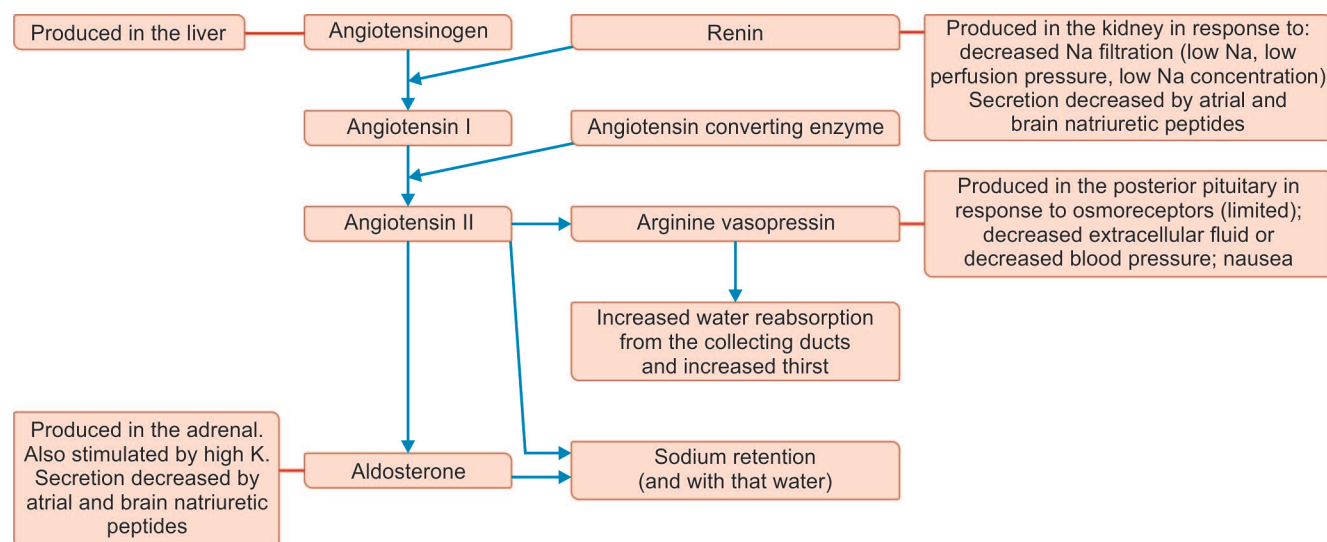

There is considerable debate as to whether the hyponatremia that may occur in hospitalized children on hypotonic intravenous fluids is related to excessive fluid intake, or the hypotonic fluids administered (or possibly both). Some children may still become hyponatremic despite the administration of 0.9% NaCl. There is however, a consensus that *maintenance intravenous fluid* in sick children or following surgical procedures should be given at a rate less than that initially recommended by Holliday and Segar. Fluid overload is increasingly seen to have adverse clinical outcomes.

Following surgical procedures, particularly neurosurgical and spinal procedures there is a high incidence of hyponatremia which may be related to high arginine vasopressin levels, but has also been related to the entity of cerebral salt wasting. While the entity of cerebral salt wasting may be controversial, it is clear that in this setting, fluid restriction alone may be inadequate to improve sodium levels and administration of 0.9% NaCl (or higher concentrations) may be necessary in order to normalize dysnatremia.

While primary endocrine causes of hyponatremia are relatively rare, it is important to be aware of this possibility. The full clinical picture of adrenal insufficiency may take time to develop and may not be obvious. However, the association of low sodium levels together with high potassium levels should alert the clinician to this possibility.

**Table 3** Hyponatremia—real or not?

	Problem	Correction
Spurious hyponatremia	Contamination of the specimen with fluid that has a low sodium concentration—may occur if specimen collected from vein into which an intravenous infusion with low sodium concentration is running	Not possible, need to repeat specimen collection
Pseudohyponatremia	Specimen has high concentration of lipid (particularly seen if patient is on total parenteral nutrition) or protein	The concentration of sodium in water is normal, but each liter of serum contains less water. [True sodium] (mEq/L) = [reported sodium (mEq/L)] $\times$ [0.021 $\times$ (triglycerides in mg/dL) + 0.994]
Fictitious hyponatremia	Sodium content of the serum is normal, but concentration is decreased by the osmotic impact of hyperglycemia	Measured sodium levels decrease by approximately 1.6 mmol/L for every 100 mg/dL (approximately 5.5 mmol/L) increase in glucose concentration. Alternatively [Corrected Na] = [measured Na] + 2[(plasma glucose - 5.6)/5.6] (mmol/L)

**Flow chart 1** Regulation of sodium and water excretion

## CLINICAL FEATURES

The most common clinical features of acute dysnatremia in children relate to the central nervous system with symptoms ranging from altered behavior, changes in level of consciousness and irritability to convulsions and features of raised intracranial pressure. Although these signs and symptoms are very nonspecific, they should be taken as warning signs in any clinical situation where there are (or potentially have been) significant fluid shifts, either with loss of fluid or with administration of significant fluid volumes.

### Hyponatremia

Mild symptoms of hyponatremia include headache, nausea, vomiting and anorexia. There may be development of altered sensorium, abnormal behavior, hallucinations, seizures and respiratory depression. Severe cerebral edema may manifest with abnormal posturing, abnormal blood pressure, prolonged seizures, and coma.

### Hypertnatremia

Symptoms of hypertnatremia include high-pitched cry, irritability, lethargy, abnormal sensorium, seizures and hypertonia. Few children may have rhabdomyolysis.

There are high-risk situations which include:

- Children with renal disease, cardiac disease (particularly with use of diuretics), infections (particularly of the central nervous

system or the respiratory system) or following either injury or surgical procedures

- Children who are receiving significant volumes (> 24% of total daily fluid intake) of intravenous fluids
- Children have been given hypertonic saline infusions or other osmotically active solutions such as mannitol.
- Children with skin conditions that are related to excessive fluid losses (including burns, Stevens Johnson syndrome, extreme prematurity, etc.)
- Situations in which there are marked elevations in glucose levels—as may happen in diabetes mellitus.

One of the challenges with the diagnosis of dysnatremia in children is the overlap of the clinical features with the clinical features of the underlying and contributory conditions. Thus the diagnosis is likely to be missed unless the possibility is frequently considered. Chronic dysnatremia may develop in children on diuretic therapy and with cirrhosis, and correction of the dysnatremia has been associated with improved quality of life.

## APPROACH TO DIAGNOSIS

Dysnatremia should be considered within the clinical context mentioned above, but particularly when patients present with altered level of consciousness, irritability and/or seizures. The diagnosis is made by direct measurement of serum sodium levels. As shown in **Table 4**, there are a number of situations where the

reported value of sodium may be lower than the actual level, and this may be important both in the diagnosis of hyponatremia, and when considering the severity of hypernatremia. Total fluid overload since admission can be determined by careful input and output measurements.

## MANAGEMENT

As soon as the diagnosis of dysnatremia has been made, measures should be taken to provide an understanding of the etiology of the condition and to correct sodium levels to normal. An underlying principle is that if dysnatremia is associated with severe symptoms such as seizures, the initial correction should be relatively rapid. In all other settings the sodium concentration should be corrected at a rate that does not exceed 0.5–1 mmol/L per hour.

### Hypernatremia

Ongoing hypernatremia is associated with ongoing brain injury. If the patient is hypovolemic, then fluid boluses with approximately 150 mmol/L of Na should be given until the patient is normovolemic. Thereafter, the fluid administration would depend on the cause of the hypernatremia. In settings where excessive fluid losses are ongoing and dehydration is part of the cause, therapy should focus on limiting ongoing losses where possible (this may include the administration of vasopressin in diabetes insipidus, obtaining skin cover for burns, etc.).

If the patient is dehydrated, then maintenance fluids together with rehydration fluids should be administered. As it may be impossible to predict ongoing fluid losses, it is reasonable to estimate the fluid requirements (planning to provide rehydration over approximately 48 hours) and then monitor the patient at regular intervals (using weight, urine output and serum electrolyte levels) to ensure that the patient is actually being rehydrated. The sodium content of the fluid to be administered would depend to some extent on the underlying pathology. Some authors have recommended fluid replacement with isotonic saline, while other studies have shown that patients with severe hypernatremic dehydration related to gastroenteritis can be safely rehydrated using a 0.45% saline solution. Measurement of the sodium content of the fluids that are being lost may provide some insight into what replacement fluids can be administered. In a child with diabetes insipidus, the child's hyponatremia will respond to administration

of vasopressin or its analog—1-deamino-8-D-arginine vasopressin; however, one should be careful about intake of electrolyte-free water during this period as there may be rapid fall in serum sodium.

Some patients can have oral fluid administration for correction of hypernatremia, but great care should be exercised if there is a depressed level of consciousness.

### Hyponatremia

If there is hyponatremic encephalopathy, then emergency therapy with 2 mL/kg bolus of 3% NaCl (maximum 100 mL) can be given (a similar sodium load could be used if only 5% solutions are available), and be repeated 1–2 times if symptoms persist. Once acute symptoms have resolved sodium concentrations should be corrected at a rate of 0.5–1 mmol/L per hour.

Again the principles in achieving that rate of correction depend on adjusting fluid intake (if fluid overload is a component of the problem then restriction of fluid intake would be appropriate).

## OUTCOMES/ PROGNOSTIC FACTORS

There is increasing recognition that dysnatremia is associated with adverse outcomes in adults, in children and in neonates. In many of these settings, it is difficult to separate the prognosis related to dysnatremia from the prognosis of the underlying illness, but there is evidence that the outcomes are related to the severity of the dysnatremia. However, there is data from adult intensive care studies to show that correction of dysnatremia is associated with improved outcome.

## PREVENTION

Within the healthcare environment, prevention needs to be focussed on identification of high-risk patients, careful management of intravenous fluid administration and appropriate monitoring. In general hypotonic intravenous solutions with [Na] of less than 70 mmol/L should not be given to hospitalized children or those following surgical interventions (in the early neonatal period there may still be a place for hypotonic intravenous fluids particularly in infants with high insensible fluid losses). A number of international guidelines have recommended the removal of such hypotonic fluids from pediatric clinical areas. Several authors have recommended the use of intravenous fluids containing at least 130 mmol/L of Na for maintenance fluids in children. There are even

**Table 4** Causes of dysnatremia

recommendations that children with dehydrating diarrhea should be rehydrated with intravenous fluids containing 0.9% saline, but these recommendations have not been tested in settings with a high incidence of severe dehydrating gastroenteritis.

Children on enteral feeds are at less risk of developing dysnatremia than those given significant volumes of intravenous fluids, so enteral feeds should be provided to children where at all possible. When intravenous fluids are given in volumes exceeding 30% of recommended daily fluids, then serum sodium levels should be checked at least daily.

Probably the most important consideration in the prevention of dysnatremia is the recognition that the condition is common in hospitalized children, particularly those on intravenous fluids and can be largely avoided by careful monitoring of fluid and electrolyte intake of children at risk, and regular monitoring of serum sodium levels.

Outside the hospital environment, dysnatremia is probably best addressed by general education (particularly directed at mothers) of the risks associated with water and electrolyte imbalance in children.

### IN A NUTSHELL

1. Dysnatremia (serum sodium < 135 mmol/L or > 145 mmol/L) is common in sick children of all ages and is associated with increased morbidity and mortality.
2. Children are at particular risk of dysnatremia in the settings of: significant fluid administration (particularly intravenous) or losses, renal disease, cardiac disease (particularly with diuretic therapy) or in the setting of acute respiratory or neurological disease.
3. Children are at significant risk of hyponatremia if given hypotonic fluids as *maintenance fluid* in the perioperative period particularly if surgery has involved the spine and the brain.
4. Dysnatremia may have devastating effects on the brain with acute presentations of seizures and long-term adverse consequences.
5. Most cases of hyponatremia could be avoided by careful implementation of fluid guidelines together with careful monitoring of children at risk.

## Chapter 5.6

# Potassium

Virendra Kumar

Potassium, an essential cation for cellular functions, is widely distributed in body. It is one of the most commonly affected ions in sick children. The spectrum of disorders related to the potassium homeostasis may vary from asymptomatic to serious life-threatening state, requiring immediate intervention. This section will deal with the physiological aspects of potassium homeostasis and disorders related to them.

### BASICS OF POTASSIUM PHYSIOLOGY

The total body content of potassium may vary from person to person depending upon the muscle mass. In an average person it is approximately 50 mEq/kg body weight. Nearly 98% of potassium is distributed in the intracellular compartment with a concentration of 140–150 mEq/L. Three-fourths of intracellular potassium is in muscles. Only 2% of the potassium is in the extracellular compartment, mostly in bones. Normal plasma concentration of 3.5–5.2 mEq/L represents about 0.4% of total body potassium.

The intracellular to extracellular potassium gradient (38:1) is maintained by sodium potassium adenosine triphosphatase (Na-K-ATPase) and selective potassium channels located in the cell membrane. Na-K-ATPase allows active transport of potassium into the cells whereas selective channels allow passive diffusion of potassium out of cells. Potassium gradient across the cell membrane helps in maintaining resting membrane potential. Potassium is also required for generation of action potential and depolarization.

*Potassium homeostasis* depends on a number of renal and extrarenal factors, such as intake, gastrointestinal and urinary losses and transcellular shift. Daily requirement of potassium is about 1–2 mEq/kg. Nearly 90% is absorbed in small intestine and eliminated through kidney; 5–10% is excreted in stool and less than 5% in sweat. Potassium losses in stool may be increased in diarrhea and other related disorders. Colonic secretion of potassium in response to hyperkalemia is also increased under the influence of aldosterone and glucocorticoids.

Transcellular shift of potassium is an early protective measure against loss of excess of potassium and helps maintaining the electroneutrality between intracellular and extracellular compartment without altering the total body potassium. Major factors which influence transcellular shift are metabolic acidosis, alkalosis, insulin, glucagon, catecholamine, hyperosmolality, failure of Na-K-ATPase pump, and cellular injury. Insulin and  $\beta$ -adrenergic receptor agonist activate Na-K-ATPase and promote potassium uptake by the cells. Acidosis promotes extracellular movement of potassium, whereas alkalosis leads to potassium uptake by the cells. Extracellular increase in osmolality results in water movement from intracellular to extracellular space and potassium moves out of cells passively as dragging effect. Hyperkalemia itself stimulate insulin secretion and thereby intracellular movement of potassium.

### Excretion of Potassium

Kidney is the primary organ responsible for excretion of 90% of the potassium. Colonic secretion may contribute to a small amount. In persons with normal renal function, potassium is filtered freely from the glomerulus. Nearly 85–90% of the potassium is reabsorbed up to distal tubules and only 10–15% reaches cortical and outer

medullary collecting duct, which is the principle site of regulation of potassium excretion. They have the capacity to reabsorb and secrete as well into the lumen. In case of potassium depletion, absorption exceeds the secretion and urinary  $K^+$  levels of less than 15 mEq/day suggest renal potassium conservation.

Potassium secretion in cortical collecting duct (CCD) is regulated mainly by the aldosterone secreted from adrenal cortex. Plasma concentration of potassium and sodium and water delivery to *distal convoluted tubule* also influences the regulation of potassium secretion by activating the Na-K-ATPase pump. *Antidiuretic hormone* does not contribute much to the overall potassium excretion.

Aldosterone facilitates the movement of sodium into the peripheral cells of CCD through sodium channels. Increased intracellular sodium concentration stimulates Na-K-ATPase activity and potassium is secreted into the lumen to balance the negative luminal charges. Intracellular concentration gradient also allows the passive diffusion of potassium from the cells through potassium channels.

The net  $K^+$  secretion at CCD level can be evaluated by transtubular  $K^+$  concentration gradient (TTKG), which is the ratio of  $K^+$  concentration in the lumen of CCD to that of plasma.  $K^+$  concentration in CCD lumen can be calculated by urinary  $K^+$  concentration divided by the ratio of urinary and plasma osmolality (Uosm and Posm).

$(K^+)_{CCD} = (K^+)_{urine} / (Uosm/Posm)$ ;  $TTKG = (K^+)_{CCD} / (K^+)_{plasma}$ . In hypokalemic children TTKG of more than 4, indicates renal loss of  $K^+$ , whereas in hyperkalemic children TTKG of less than 8, suggests impaired renal secretion of potassium.

### HYPOKALEMIA

Hypokalemia is defined as plasma potassium concentration of less than 3.5 mEq/L. It is reported in 20–68% of hospitalized patients in different clinical settings. In addition to plasma potassium concentration, intracellular to extracellular potassium ratio and concentration gradient across the membrane also effect the polarization of cell membrane and its function. Hypokalemia possesses a greater risk of complications in cases with pre-existing heart disease, liver disease, severe acute malnutrition, respiratory disease or on ventilatory support.

### Etiology

Reduction of plasma potassium levels may broadly be attributed to inadequate intake of some duration, result of transcellular shift, or renal and extrarenal losses. However, in day to day practice, errors related to sample collection, processing or estimation causing spurious hypokalemia are also common.

*Inadequate oral intake* or intravenous supplementation of potassium may result in hypokalemia, though renal conservation of potassium helps preventing it unless the net intake is less than 15 mEq/day. However, it takes 3–5 days for effective renal conservation.

*Transcellular shift* of potassium can give rise to hypokalemia without total body potassium depletion. Beta-adrenergic receptor agonist (catecholamine, bronchodilators), insulin and alkalosis are commonly associated with intracellular shift. Theophylline by blocking the degradation of cyclic *adenosine monophosphate* and barium by blocking the potassium channels can also lead to hypokalemia. Hypokalemic periodic paralysis and thyrotoxicosis are rare causes but may be associated with massive shift of potassium into the cells.

*Gastrointestinal (GI) losses of potassium* in children are commonly observed with large volume diarrhea. Fecal content of potassium in diarrhea is usually 30–35 mEq/L; in severe diarrhea

the losses may exceed 100 mEq in a day. Persistent vomiting or nasogastric aspirates, losses from GI fistula and congenital chloride losing diarrhea are the other causes which can lead to GI losses. Potassium content of gastric fluid is not more than 10 mEq/L and hypokalemia observed with upper GI losses is also contributed by urinary loss of potassium in response to hypovolemic stimulation of aldosterone.

*Increased urinary loss of potassium ( $K^+$ )* alone or in addition to other losses is a common cause of hypokalemia in children. Hypokalemia due to renal loss can be categorized on the basis of acid-base status. *Hypokalemia with normal acid-base status or metabolic acidosis* is seen in diuretic phase of acute tubular necrosis, postobstructive uropathy, renal tubular acidosis type I and II, osmotic diuresis, hypomagnesemia and drugs. Commonly associated drugs are diuretics, aminoglycosides, and amphotericin B. Children having *hypokalemia with alkalosis* require estimation of urinary chloride. Normal urinary chloride varies from 10 mEq/L to 20 mEq/L. Cases presenting with *hypokalemia, alkalosis and low urinary chloride* are generally secondary to conditions resulting in chloride loss, such as postdiuretic phase, chloride losing diarrhea, persistent vomiting or cystic fibrosis.

*Hypokalemia, alkalosis and high urinary chloride with normal blood pressure* is usually associated with diuretics, Bartter or Gitelman syndrome. In thick ascending limb of loop of Henle [thick ascending limb (TAL)], defect in  $Na^+-K^+-Cl^-$  co-transport results in poor sodium reabsorption, salt wasting, and elevated renin and aldosterone levels in Bartter syndrome. A significant proportion of filtered calcium is also reabsorbed in TAL; defect in TAL also results in poor calcium absorption and hypercalciuria. Loop diuretics act on  $Na^+-K^+-Cl^-$  co-transporter in TAL and prolonged use of them can give rise to Bartter like picture. Mutations in gene encoding for thiazide-sensitive  $Na^+-Cl^-$  co-transporter in distal tubule are responsible for Gitelman syndrome. Since calcium absorption is normal hypercalciuria is not seen. Hypocalciuria, hypomagnesemia and late presentation are distinguishing feature of Gitelman syndrome.

A similar combination of metabolic alkalosis, hypomagnesemia and hypocalciuria is also seen in epilepsy, ataxia, sensorineural hearing loss and tubulopathy (EAST) syndrome. Defect in gene encoding for potassium channels present in kidney, ear and brain results in EAST.

Cases with *hypokalemia, alkalosis and hypertension* are classified on the basis of mineralocorticoid activity. Aldosterone, being a primary regulator of potassium loss in urine, raised levels increases  $Na^+-K^+-ATPase$  activity, resulting in sodium retention and potassium secretion into the tubular lumen and excretion in urine. This leads to the development of hypokalemia and hypertension. Primary hyperaldosteronism is seen in adrenal hyperplasia, adenoma or glucocorticoids remediable aldosteronism. In all these cases, PRA activity is low. Secondary hyperaldosteronism may result from decreased intravascular volume or increased renin activity. Elevated levels of mineralocorticoids other than aldosterone such as cortisol, deoxycorticosterone and exogenous steroids can also produce hypertension and hypokalemia.

Similarly, nonaldosterone upregulation of sodium ( $Na^+$ ) channels is seen in cases with Liddle syndrome. Mutations of  $\beta$  or  $\gamma$  subunit of intracellular carboxyl terminal of  $Na^+$  channels of distal tubules increases  $Na^+$  conductance resulting in more of  $Na^+$  absorption and  $K^+$  secretion into the tubular lumen and hypokalemia.

### Pathological Changes Observed With Hypokalemia

Reversible epithelial vacuolization of proximal tubules are early changes observed with hypokalemia. In cases with persistent hypokalemia, interstitial lymphocytic infiltration, scarring and

tubular atrophy may be seen. Rarely, rhabdomyolysis may be seen with severe persistent hypokalemia.

### Clinical Features

Clinical manifestations are primarily dependent on the extracellular potassium concentration and the gradient across the membrane. Acute changes in plasma potassium may affect neuromuscular, cardiac, renal and GI system. Hypokalemia may be graded on the basis of plasma potassium concentration as mild (3.5–3 mEq/L), moderate (3–2.5 mEq/L) or severe (< 2.5 mEq/L). Mild hypokalemia is generally asymptomatic, however worsening of pre-existing heart disease, liver disease or ventilatory functions is known to occur even with mild hypokalemia.

Moderate hypokalemia results in muscle weakness, hypotonia, hyporeflexia, decrease bowel movements (distension, feed intolerance). Severe hypokalemia may lead to ascending paralysis, respiratory failure, and cardiac dysrhythmia. Consciousness remains normal unless there is some other cause to affect it. Persistent hypokalemia may present with polyuria and polydipsia similar to diabetes insipidus. Inability of the kidney to excrete bicarbonate, increased collecting duct secretion of  $H^+$  ion and increased chloride loss in urine contribute to metabolic alkalosis in hypokalemia, which can further reduce the plasma potassium levels.

### Electrocardiographic Changes

All cases with hypokalemia may not show electrocardiographic (ECG) changes. Appearance of U wave with amplitude more than that of T wave, ST segment depression and flattening of T wave are commonly seen in moderate hypokalemia. Prolongation of PR interval, QRS widening and ectopic rhythm usually suggests severe hypokalemia.

### Management

All children should be clinically evaluated for the underlying disease, clinical features, ECG changes, nutritional status, hydration, hypertension and status of respiratory, cardiac, liver and renal functions. Exposure to drugs especially digoxin, insulin,  $\beta$  agonist, amphotericin B, diuretics and steroids in the recent past should also be checked. Initial investigations required, in addition to plasma/serum  $K^+$  are *arterial blood gas*, electrolytes, blood glucose, osmolality and urinary potassium and chloride.

Most of the children with plasma potassium levels between 3 mEq/L and 3.5 mEq/L are asymptomatic and many have spurious hypokalemia. True asymptomatic hypokalemia may be managed with dietary or oral potassium supplementation, 2–4 meq/kg/day mixed with feed to avoid GI irritation. If oral potassium cannot be given, intravenous fluid concentration of potassium may be increased from maintenance of 20 mEq/L to 40 mEq/L and then reassess every 6–8 hours for further need. Each milliliter of injection potassium chloride (KCl), 15% solution provides 2 mEq of potassium and should be diluted at least 50 times of its volume. Simultaneously appropriate replacement of ongoing losses and correction of underlying cause should also be considered.

Children with severe hypokalemia with respiratory failure or cardiac dysrhythmia should initially be supported for airway, breathing and circulation. Hypokalemia should be treated either with increasing the intravenous fluid concentration of potassium to 60 mEq/L or with a rapid infusion of 0.5–1 mEq/kg (maximum 40 mEq) of KCl diluted in 5–10 mL/kg of saline (dextrose may stimulate insulin secretion and shift of  $K^+$  into the cells) to be given over 30–60 minutes under strict monitoring in pediatric intensive care unit (PICU). As the plasma  $K^+$  concentration improves the rate of infusion should be reduced to maintenance. Children who respond poorly to potassium replacement should also be checked and corrected for hypomagnesemia and hypophosphatemia.

## HYPERKALEMIA

Hyperkalemia is defined as plasma potassium levels of greater than 5.5 mEq/L. Though less common than hypokalemia, the serious consequences such as arrhythmia and sudden death are more common. Based on the plasma  $K^+$  concentration hyperkalemia can be categorized as mild, (5.5–6.5 mEq/L), moderate (6.6–8 mEq/L) or severe ( $> 8$  mEq/L). Rapidly rising potassium levels, presence of hypoxia or acidosis and compromised cardiac status are other contributory factors for complications.

### Etiology

*Spuriously raised levels* may be due to release of potassium from hemolyzed RBCs at the time of sampling or due to delay of more than 3 hours in sample processing at room temperature. Release of potassium during clot formation may result in about 0.4 mEq/L higher potassium level in serum compared to plasma. This may become significant if there is marked leukocytosis or thrombocytosis.

*True hyperkalemia* may either be due to increased load of potassium, impaired renal excretion or transcellular shift of potassium. In a given case there may be more than one mechanism responsible for hyperkalemia. Since kidneys have potential of excreting large amount of potassium, generally there is some degree of renal impairment associated with increased potassium load to cause hyperkalemia.

An excess load of  $K^+$  from exogenous source (potassium salt supplements, stored blood transfusion) or endogenous source (intravascular hemolysis, resolving hematoma, rhabdomyolysis and tumor lysis) may result in hyperkalemia.

Renal excretion of potassium is influenced mainly by the sodium and water delivery to distal cortical tubules and functional aldosterone. Potassium excretion is generally maintained within normal range unless GFR falls below 10 mL/min; however, their ability to handle excess load is seriously compromised at GFR less than 20 mL/min. Reduction of GFR is primarily a part of acute kidney injury or chronic kidney disease due to a number of renal or systemic diseases. Reduced sodium and water delivery may either be due advanced kidney disease or volume depletion as a result of dehydration, shock, or cardiac failure.

Aldosterone helps in sodium reabsorption and potassium excretion in urine and hypoaldosteronism usually results in hyperkalemia. Hypoaldosteronism with high renin levels indicate primary adrenal disease, aldosterone synthase deficiency or use of drugs (angiotensin converting enzyme inhibitor or receptor blockers). Renin produced from kidney converts angiotensinogen to angiotensin I which is then converted to angiotensin II with the help of converting enzyme. Angiotensin-II stimulates adrenals for aldosterone synthesis. If this stimulus is lost (low renin state), aldosterone levels are also reduced. This is commonly seen in *systemic lupus erythematosus* (SLE), interstitial nephritis, obstructive uropathy, and nonsteroidal anti-inflammatory drugs. End organ failure to aldosterone causes functional hypoaldosteronism which is seen in SLE, sickle cell disease, postrenal transplant and use of potassium sparing diuretics.

Transcellular shift of  $K^+$  from intracellular to extracellular space is commonly seen in acidosis, hypertonicity, exercise, diabetes, myolysis, and drugs such as digoxin,  $\beta$ -blockers, and succinylcholine. Extensive muscles or cellular injury may result in shift of intracellular potassium to plasma. Hyperkalemia due to cellular damage is also commonly associated with hyperphosphatemia.

### Clinical Features

In children, hyperkalemia is often asymptomatic and picked up on ECG monitoring or routine testing. Some of the nonspecific

symptoms of hyperkalemia include paresthesiae, muscle cramps, muscle weakness, paralysis and symptoms related to cardiac rhythm disturbances (palpitation, missed beat, syncope).

### Electrocardiographic Changes

These correlate well with plasma  $K^+$  levels. However, cases even with early ECG changes may suddenly develop fatal cardiac rhythm disturbances. Earliest ECG changes with hyperkalemia (plasma potassium 6–7 mEq/L) are tall ( $> 50\%$  of QRS) and peaked T waves, best observed in chest leads. With increasing levels of potassium, flat P waves, prolonged PR interval and wide QRS complex become evident (plasma potassium 7–8 mEq/L). Absence of P waves, wide QRS complex to appear as *sine wave* or progressing to asystole or ventricular fibrillation indicate severe hyperkalemia.

### Management

Clinical evaluation of children with hyperkalemia should include detailed history and examination, especially for hydration, hypertension, hyperpyrexia, hyperglycemia, hypoxia, acidosis, and cardiac and renal status. ECG should be done for changes in cardiac rhythm. If plasma  $K^+$  is more than 6.5 mEq/L or ECG abnormalities are detected, emergency treatment should be initiated.

The priority of treatment execution should be: (1) withdrawal of source of excess  $K^+$  if any. In case blood transfusion is urgently needed use of fresh and washed RBCs are recommended; (2) stabilization of myocardial cells; (3) rapid reduction of plasma  $K^+$  levels with transcellular shift; (4) enhance  $K^+$  elimination from body; and (5) treatment of the underlying cause.

For membrane stabilization, calcium gluconate is used as 10% solution, 0.5–1 mL/kg (maximum 10 mL) 1:1 diluted with saline over 10 min under cardiac monitoring. If slowing of heart rate is observed then slow the rate of infusion. If patient is taking digitalis, give infusion over 30 min. Onset of action is within 1 min and lasts up to 20–60 min.

Transcellular shift may be achieved by using glucose insulin infusion. Infants and young children should receive 2 mL/kg of 25% dextrose with 0.1 unit/kg of regular insulin to be infused over 30 min. For older children use 50 mL of 50% dextrose with 10 units of regular insulin to be infused over 30 min. If blood glucose level is more than 300 mg/dL, insulin may be given alone. All cases should be monitored for hypoglycemia.

Short acting  $\beta$ -agonist is also useful in intracellular shift of potassium. Salbutamol, 2.5–5 mg in 3–4 mL of saline may be nebulized over 20 min and may be repeated if required. It has onset within 30 min and effect lasts for about 2 hours.

If there is nonanion gap metabolic acidosis, 1–2 mEq/kg of sodium bicarbonate may be given intravenously; onset occurs within 30 min and lasts for 60 min.

Elimination of  $K^+$  may be achieved by using ion-exchange resin, such as sodium polystyrene sulfonate (Kayexalate), 1–2 g/kg orally or per rectally as retention enema. Onset of action takes about 60–90 min. Each gram of kayexalate will exchange 1 mEq of potassium with 2 mEq of sodium. The dose may be repeated after 2–4 hours.

Intravenous furosemide 1–2 mg/kg may also help in excretion of  $K^+$  if kidney functions are normal.

Hemodialysis can lower the  $K^+$  levels by 1.2–1.5 mEq/h. Peritoneal dialysis with potassium-free fluid is also an effective alternative especially if hemodialysis is not possible. It removes  $K^+$  slowly and chances of rebound hyperkalemia are much lesser than hemodialysis. A variable degree of renal dysfunction coupled with excess load of potassium, infection, medications, decreased renal perfusion or obstruction may also be contributing to hyperkalemia and should be addressed appropriately.

### IN A NUTSHELL

1. Normal plasma  $K^+$  levels of 3.5–5.2 mEq/L represents about 0.4% of total body potassium; intracellular fluid to extracellular fluid potassium gradient (38:1) is maintained by (Na-K-ATPase) and selective potassium channels located in the cell membrane.
2. Hypokalemia (plasma  $K^+ < 3.5$  mEq/L) may be graded as mild (3.5–3 mEq/L), moderate (3–2.5 mEq/L) or severe ( $< 2.5$  mEq/L).
3. Electrocardiographic changes of hypokalemia include U wave with amplitude more than that of T wave, ST depression and flat T wave
4. Transcellular shift, GI and renal loss of potassium contribute to hypokalemia in most cases.
5. Slow correction of hypokalemia with 40–60 mEq/L of  $K^+$  in maintenance fluid is safe. Injection KCl, 15% solution (2 mEq/mL) should be diluted at least 50 times of its volume. Rapid infusion of 0.5–1 mEq/kg (maximum 40 mEq) of KCl diluted in 100 mL of saline (dextrose stimulate insulin secretion and shift of  $K^+$  into the cells) may be given over 30–60 min under strict monitoring in PICU in cases of severe hypokalemia.
6. Hyperkalemia ( $K^+ > 5.5$  mEq/L) can be categorized as mild (5.5–6.5 mEq/L), moderate (6.6–8 mEq/L) or severe ( $> 8$  mEq/L).
7. Rapidly rising potassium levels, presence of hypoxia or acidosis and compromised cardiac status are other contributory factors for complications.
8. ECG changes of hyperkalemia include tall ( $> 50\%$  of QRS) T waves, flat P waves, prolonged PR interval and wide QRS.
9. Potassium excretion is maintained within normal range unless GFR falls below 10 mL/min; however, their ability to handle excess load is seriously compromised at GFR less than 20 mL/min.
10. Treatment of hyperkalemia should aim at stabilization of myocardium, reduction of plasma  $K^+$  levels, enhance elimination and treatment of underlying cause.

## Chapter 5.7

# Magnesium Balance

Virendra Kumar

Magnesium is an important intracellular cation, which is widely distributed in body. Though isolated disorders of magnesium are less frequently observed in clinical practice, the association with disorders of potassium, sodium, calcium and phosphate are not uncommon. Primary manifestations of magnesium abnormalities are often subtle and easily get confused with disorders of potassium and calcium. This section will deal with the physiological aspect of magnesium homeostasis and disorder related to them.

### Basics of Magnesium Physiology

Magnesium is the second most common intracellular cation, required for enzymatic activity of ATPase, kinases, and cyclases. It also influences the cell membrane stabilization, neuromuscular functions, cardiac conduction and parathyroid hormone (PTH) regulation. Total body contents of magnesium are approximately 22–26 g in adults, distributed largely in intracellular space (bones, muscles, liver and soft tissues). Only 1% is distributed in extracellular space. Nearly 30% of plasma magnesium is protein bound and only 70% of magnesium is exchangeable and filtered in the kidney. Most of the filtered magnesium (60–70%) is reabsorbed in loop of Henle and only 5–10% is reabsorbed in distal collecting ducts.

The normal plasma levels of magnesium range from 1.2 mEq/L to 1.9 mEq/L (1.5–2.3 mg/dL). Daily requirement of magnesium is about 4–5 mg/kg/day. Children with chronic illnesses or severe malnutrition require higher amount of magnesium. Magnesium is available in green leafy vegetables, cereals, pulses and animal foods. Dairy products and processed food are poor source. About 40% of dietary magnesium is absorbed primarily in the jejunum and ileum. Intestinal absorption is increased in deficient state with low magnesium intake. PTH and vitamin D may also help gut absorption. Increased intestinal mobility and presence of phosphate, oxalate and high fiber may reduce the net absorption. Magnesium balance is maintained by intake, gut absorption and renal excretion. There is no known hormonal control of renal absorption or excretion though PTH and insulin may play some role. Among all, renal regulation plays a crucial role in most cases. Higher levels of magnesium in the plasma facilitate renal excretion. Alkalosis, excess catecholamine state (trauma, tumor, infusion of catecholamines) and insulin therapy can cause intracellular shift of magnesium.

### Therapeutic Uses of Magnesium

Magnesium has been used as a therapeutic agent in the treatment of many disorders. It has been used as a cathartic agent for long time. The other known uses are in asthma, long QT syndrome and other refractory arrhythmias.

### HYPOMAGNESEMIA

Hypomagnesemia is defined as plasma magnesium levels less than 1.2 mEq/L. The reported prevalence of hypomagnesemia varies from 7% to 11% in hospitalized patients. In critically sick patients and those with other electrolyte abnormality, prevalence of hypomagnesemia is even higher. Hypomagnesemia may either be caused by low intake, intracellular redistribution or excessive loss from the gut or kidney.

### Etiology

Hypomagnesemia should always be suspected in children with severe acute malnutrition, chronic diarrhea, refractory hypokalemia

and hypocalcemia, and ventricular arrhythmias. Other important causes include major resection of bowel, acute pancreatitis, diabetes mellitus, hyperthyroidism, primary hyperparathyroidism and hyperaldosteronism. Prolong use of diuretics, aminoglycosides, amphotericin B, pentamidine, and cisplatin are also known to cause hypomagnesemia. Primary renal disorders such as Bartter's and Gitelman's syndrome, familial hypomagnesemia, postobstructive and post-transplant nephropathy may also be associated with hypomagnesemia.

### Clinical Manifestations

Most of the clinical manifestations are nonspecific and indistinguishable from hypocalcemia and hypokalemia, including lethargy, tremors, confusion, fasciculation, tetany, seizures, and cardiac arrhythmias. However, persistence of these symptoms even after correction of calcium and potassium levels or failure to correct their levels should be taken as an indicator of hypomagnesemia.

### Diagnosis

High index of suspicion of hypomagnesemia in a given suggestive background is the most crucial part of evaluation. Estimation of serum and urinary magnesium, fractional excretion of magnesium may help to support the diagnosis. In presence of hypomagnesemia (serum magnesium < 1.2 mEq/L), 24-hour urinary excretion of magnesium of more than 2 mEq/day or fractional excretion of more than 2% suggest a renal loss of magnesium. Fractional excretion can be calculated as  $[U Mg \times Pcr \div (0.7 \times P Mg) \times U cr] \times 100$ . Plasma concentration of magnesium is multiplied by 0.7 as 30% is protein bound and only 70% of magnesium is in unbound form and filtered in the kidney.

### Electrocardiographic Changes

These include prolong PR and QT interval, T wave flattening wide QRS complex or ventricular arrhythmia.

### Treatment

#### Symptomatic Cases

Children with ECG abnormalities should be treated with IV infusion of magnesium sulfate 25–50 mg/kg (0.05–0.1 mL/kg of 50% solution) over 30 min. Infusion may be repeated every 6 hourly for 2–3 doses if serum levels remain less than 1 mEq/L or symptoms/ECG abnormalities persist. To restore the body stores, slow infusion with maintenance fluids may be continued for 3–5 days. Serum Mg levels should be checked to keep the serum magnesium levels less than 2.5 mEq/L. Higher doses or rapid infusion may increase the serum levels more than 2.5 mEq/L which can promote renal excretion without contributing much to body stores. Deep tendon reflexes should also be checked and recorded with the start of infusion. If signs of hypermagnesemia (hypotension, bradycardia or loss of deep tendon reflexes) develop, therapy should be discontinued and serum magnesium levels should be checked.

#### Asymptomatic Cases

Those without ECG abnormalities and gastrointestinal disorders should be treated with magnesium rich diet and oral magnesium supplementation. Magnesium is available as a salt with sulfate, gluconate, hydroxide and chloride. Magnesium gluconate is preferred for oral supplementation as it is better absorbed and causes fewer diarrheal episodes. Oral magnesium is usually started with 30 mg/day in 3–4 divided doses and gradually increasing to 120 mg/day. Concomitant deficit of calcium and potassium should also be corrected. Care should be taken in cases with renal impairment to use lower doses and frequent monitoring.

## Prophylaxis

High-risk children for magnesium deficiency such as patients receiving total parenteral nutrition, long-term diuretic therapy and those with chronic diarrhea or severe malnutrition should have serum magnesium checked regularly and supplemented with magnesium in the doses of 4–5 mg/kg/day.

## HYPERMAGNESEMIA

Hypermagnesemia is defined as serum Mg levels more than 2.2 mEq/L.

### Etiology

Excessive intake and reduced glomerular filtration rate to less than 30 mL/min are most common factors implicated in hypermagnesemia. In children hypermagnesemia is rare with normal renal functions as higher serum levels promote renal excretion. However, excessive intake of magnesium can result in hypermagnesemia in neonates and young infants because of their reduced renal ability to excrete the excess load. Babies born to mothers with eclampsia who have received higher doses of magnesium are also at a higher risk. Excessive intake of cathartics has also been reported to cause hypermagnesemia in children. Addison's disease, hypothyroidism, extensive tissue injury or tumor lysis and acute acidosis (transcellular shift) are other conditions may be associated with hypermagnesemia.

### Pathogenesis

Hypermagnesemia prevents the release of presynaptic acetylcholine and blocks the neuromuscular transmission. It also depresses the conduction system of the heart and the sympathetic ganglia. Hypermagnesemia per se can reduce the serum calcium levels partly due to its suppressive effect on PTH secretion. Calcium is a natural antagonist of magnesium at the neuromuscular junction; hypocalcemia therefore can exaggerate the effects of hypermagnesemia.

### Clinical Manifestations

These depend on serum levels. Cases with serum magnesium levels less than 4.5 mg/dL (< 3.7 mEq/L) are mostly asymptomatic. Levels between 4.5 mg/dL and 7 mg/dL (3.7–5.7 mEq/L) manifest with lethargy, poor feeding, nausea, flushing and poorly elicitable deep tendon reflexes. Levels between 7 mg/dL and 11 mg/dL (5.7–9 mEq/L) manifest with absent tendon reflexes, hypotension and ECG abnormalities (prolong PR and QT interval and wide QRS). Heart block, respiratory failure and cardiac arrest can occur if levels are more than 11 mg/dL (9 mEq/L).

### Treatment

High index of suspicion in any patient receiving magnesium therapy, especially with impaired renal functions generally form the basis for testing for magnesium in most of the cases.

### Symptomatic Cases

Symptomatic cases with neurological, cardiac or respiratory compromise should be managed with ventilatory support and

cardiac stabilization using intravenous 10% calcium gluconate 0.5–1 mL/kg (maximum 10 mL) 1:1 diluted with saline over 10 min under cardiac monitoring. The dose may be repeated if required. Glucose insulin infusion as used in hyperkalemia can also help in transient reduction of serum levels. Cases with kidney disease should be considered for hemodialysis or peritoneal dialysis. Neonates may also be considered for exchange transfusion.

### Asymptomatic Cases

Asymptomatic cases with normal renal functions can be managed with withdrawal of source of magnesium, correction of hydration and loop diuretics to promote renal excretion. Diuretics however, can also cause loss of calcium in urine and hypocalcemia which can potentiate the manifestations of hypermagnesemia.

## IN A NUTSHELL

1. Normal serum levels of magnesium range from 1.2 mEq/L to 1.9 mEq/L (1.5–2.3 mg/dL). Hypomagnesemia is defined as serum magnesium levels of less than 1.2 mEq/L.
2. Electrocardiographic changes of hypomagnesemia includes prolonged PR and QT interval, T wave flattening wide QRS complex or ventricular arrhythmia.
3. Symptomatic hypomagnesemia with ECG abnormalities should be treated with IV infusion of magnesium sulfate 25–50 mg/kg (0.05–0.1 mL/kg of 50% solution) over 30 min.
4. Asymptomatic children without ECG abnormalities and gastrointestinal disorders should be treated with magnesium rich diet and oral magnesium supplementation.
5. Hypermagnesemia is defined as serum Mg levels more than 2.2 mEq/L.
6. Electrocardiographic changes of hypermagnesemia include prolong PR and QT interval and wide QRS.
7. Symptomatic hypermagnesemia with neurological, cardiac or respiratory compromise should be managed with ventilatory support and cardiac stabilization and measures to enhance elimination of magnesium and treatment of underlying cause.
8. Asymptomatic cases with normal renal functions can be managed with withdrawal of source of magnesium, correction of hydration and loop diuretics to promote renal excretion.

# Section 6 DRUGS AND THERAPEUTICS

**Section Editor** Sandeep B Bavdekar

## Chapter 6.1

### Principles of Drug Therapy

*Sandeep B Bavdekar*

Parents bring their children to doctors for multiple reasons. These include seeking advice regarding health-protective and health promotive strategies (e.g., vaccines, dietary advice); growth monitoring, undergoing a screening procedure, seeking treatment of an ongoing illness, receiving prophylaxis and follow-up for chronic illnesses. Drugs constitute the most important therapeutic tool for most of the objectives for contact; either as the primary modality or as an adjunct to another modality. This chapter discusses the general principles of drug therapy in children.

#### SPECIAL ASPECTS OF PEDIATRIC PHARMACOLOGY

Although, the pharmacological principles governing the absorption, distribution, metabolism and elimination are universal and apply to children and adults, alike; differences in body composition and in the absorptive, metabolic and excretory capabilities; pharmacokinetics and pharmacodynamics in the pediatric age group differ to an extent. Also, the pediatric age-group is not a homogeneous population: neonates, infants, young children and adolescents vary in their capabilities as well. This has implications for therapeutic indications, dose and dosage schedules, and effectiveness and safety of medicines.

#### Pharmacokinetics

##### *Drug Absorption*

Absorption from the gastrointestinal (GI) tract is dependent on gastric acid secretion, bile salt formation, gastric emptying time, intestinal motility, bowel length and microbial flora. However, newborns and children differ from adults in several aspects. These differences are responsible for the dissimilarity in the absorption of drugs in children (**Table 1**).

Children receive drugs through various parenteral routes: intravenous, intramuscular (IM), subcutaneous, intradermal, per-rectal, into the cerebrospinal fluid, etc. Intravenous route is considered the most ideal route for administering drugs with assured bioavailability. IM route is generally not preferred as neonates have hardly any muscle mass and the absorption is erratic. IM injections are painful and there is greater possibility of injury. In addition, variability in the depth of injection, muscle mass and circulatory status contributes to erratic absorption from the IM site. Per-rectal route is employed in emergency situations when quick intravenous access is not available. For example, diazepam is used to control convulsions in infants and children for a quick action. This route is quite efficient in neonates and infants.

##### *Drug Distribution*

The distribution of a drug in the body is dependent upon the physicochemical properties such as protein binding and pH. Age-dependent variables such as relative size of the total and extracellular body water compartments and fat compartment and the amount and composition of plasma proteins influence the drug distribution and are responsible for the differences in drug distribution in children and adults.

Preterm neonates (80%), full-term babies (70%) and infants (61%) have a higher percentage of their body weight in the form of water as compared to adults (50–60%). The higher total body water is almost entirely due to higher extracellular fluid (ECF) compartment and as concentrations of drugs in the ECF determine the concentrations at the receptor sites, water-soluble drugs need to be prescribed in comparatively higher (per kg body weight) doses in neonates and infants so that the desired concentrations can be achieved. The body fat composition also changes throughout childhood and adolescence and there are gender-linked differences in the body fat composition during the pubertal years. Thus, age influences the pharmacokinetic properties of the lipophilic drugs (**Table 1**).

Albumin, alpha-glycoprotein and lipoprotein are the most important circulating proteins responsible for drug binding in plasma. The concentrations of most of these proteins are lower in neonates and approach adult levels by 10–12 months of age. In addition, neonates have higher levels of fatty acids and bilirubin in the blood; which compete with drugs for protein binding sites. The net result of this reduced protein binding is that comparatively larger proportion of the drug is available in the free form and for binding to receptor sites, thereby exposing the infant to toxicity at comparatively lower drug doses.

The transport of drugs across membranes is influenced by transporters like P-glycoprotein. Although, there is only limited data; their generally lower levels in neonates and infants could influence distribution and therapeutic capabilities of those drugs that need to cross membranes to reach their site of action.

##### *Drug Metabolism*

Liver is the primary organ for drug metabolism, although the kidneys, lungs, intestines, adrenals and skin also biotransform drugs. Drug metabolism is primarily carried out through two types of reactions, viz. phase I (nonsynthetic processes consisting of oxidation, reduction, hydrolysis and hydroxylation reactions) and phase II (synthetic processes involving conjugation with glucuronide, glycine, glutathione or sulfate). All the enzyme systems have lower than adult activity in the neonatal period and the various enzyme systems mature at different age. For example, the cytochrome P450 monooxygenase system appears to mature rapidly, with metabolic activity similar to adults being achieved by 6 months of age. In contrast, glucuronide formation reaches adult values between 3rd and 4th years of life. Although, infants are regularly characterized as being slow metabolizers of drugs, some

**Table 1** Examples of effect of age on the pharmacokinetic properties of drugs

<i>Alteration as compared to adults</i>	<i>Implications with examples</i>
<b>Absorption</b>	
Neonates and infants have reduced acid-secreting capacity. The adult values (gastric pH: 2–3) are reached only by 3–7 years of age	Increased bioavailability of acid-labile drugs such as penicillin Decreased absorption and consequent reduced serum concentrations of weakly acidic drugs like phenobarbitone, requiring higher per unit body weight doses
Infants have delayed gastric emptying	Adverse effect on the absorption of less water-soluble drugs absorbed in intestine (phenytoin, carbamazepine)
Increased intestinal motility in infants	Reduction in the time of contact with absorptive surfaces results in decreased bioavailability of sustained-release preparations
Neonates have thinner and better hydrated stratum corneum and relatively larger skin surface for body weight	Enhanced transcutaneous absorption of medicines applied locally (e.g., silver sulfadiazine and topical corticosteroids)
Delayed development of intestinal flora	Impact on the bioavailability of digoxin
<b>Distribution</b>	
Higher total body water and extracellular body water in neonates	Water-soluble drugs like aminoglycosides need to be prescribed in higher per kg body weight doses so that desired drug concentrations can be achieved in the ECF and at receptor sites
Neonates and infants have lower total body fat content	Lower volume of distribution of fat-soluble drugs such as diazepam
Comparatively higher proportion of body fat in the CNS in neonates	Higher effects of lipophilic drugs such as propranolol
Presence of fetal albumin present in neonates has lower affinity for acidic drugs	Lowered affinity to phenytoin results in greater proportion of the total drug being free, higher probability of toxicity even when total plasma phenytoin levels are within the therapeutic range
<b>Metabolism</b>	
Lower activity of hepatic oxidizing systems in neonates	Slower metabolism and longer action of phenytoin, diazepam and caffeine
Reduced activity of hydrolytic enzymes in neonates	Prolonged action of local anesthetic agents in neonates Prenatal exposure to cocaine has prolonged action in neonates
<b>Excretion</b>	
The renal mechanisms are not fully developed in neonates and reach adult levels later in life	In neonates, drugs such as gentamicin are administered once a day and the frequency of administration is increased progressively to twice and then thrice a day

Abbreviations: ECF, extracellular fluid; CNS, central nervous system.

drugs (for example, theophylline, phenytoin, phenobarbitone) are more rapidly metabolized by infants than adults. There are qualitative differences, too. A drug may be preferentially metabolized by one pathway during the neonatal period (e.g., theophylline) as compared to adulthood. All these have practical implications (**Table 1**). While determining dosages of drugs that undergo hepatic biotransformation, sequence of maturation of process of drug metabolism has to be taken into account. The drugs that are metabolized at a rapid rate are required to be administered in higher doses. Thus, theophylline is administered at much higher dose and frequency during infancy than in adulthood.

### Drug Excretion

Kidney is the predominant organ concerned with drug excretion and all renal mechanisms (filtration, secretion and reabsorption) are reduced in neonates. Although, drugs are also eliminated through the GI tract, biliary tract, respiratory tract and sweat glands, these are important routes of excretion only for a few drugs. Renal excretion is dependent upon glomerular filtration rate (GFR), renal blood flow (RBF) and rate of active tubular secretion. These are dependent on age and maturity. A term infant has GFR and RBF that approximates 30% of adult values. In premature neonates, these renal capabilities are only 15% or less, depending on the degree of prematurity. The renal capacity to excrete solutes improves quickly to reach 50% of adult value by 4 weeks and equals that of adults by 9–12 months of age.

### Pharmacodynamics

Drugs act through receptors and the most receptors and basic physiological processes are present in children. Hence, generally children's responses to drugs are quite similar to adult responses. But, there are examples where these could be different. For example, despite having similar plasma warfarin concentrations, prepubertal children show significantly lower plasma concentrations of protein C and higher INR values than adults. Similarly, in vitro, the peripheral blood monocytes from infants cultured in the presence of cyclosporine, show significantly lower peripheral blood monocyte proliferation and interleukin-2 expression than peripheral blood monocytes from adults. Evidence generated mainly from animal studies indicates that differences in receptor number, density, distribution, function and affinity to ligands could be responsible for the pharmacodynamic differences between children and adults.

### Pediatric Drug Dosages

From the description above, it is amply clear that pharmacokinetic and (to some extent) pharmacodynamic profiles of drugs in children and adults differ. The organs, systems and functions mature in a nonlinear or nonuniform fashion and various functions mature at different age. Hence, a simple proportionate reduction in the adult dose is not adequate to determine a safe and effective pediatric dose. Formulae or rules providing calculations based on age or weight of the child are mere approximations and would

be applicable to some extent only in older children over the age of 8 years. The most reliable pediatric dose information, wherein the dose is given in terms of weight or surface area, is usually that provided in the package insert, the pharmacopeia, established guidelines or pediatric textbooks. For some drugs whose apparent volume of distribution is less than ECF space (less than 0.3 L/kg), a body-surface-area-based approach is preferable. For other drugs, a body-weight-based approach is more suitable and is the most frequently used method for describing pediatric doses.

### Other Considerations

**Compliance and adherence** It is obvious that drug therapy can be successful only if it is administered as per advice. Depending upon their maturity and abilities, children can take responsibility for self-administration after 8–14 years of age. Prior to this age, this responsibility is assumed by parents and guardians in the home setting and by doctors and nurses in the hospital setting. When the child is in day care or in school, other adults might share this responsibility. The administration of drugs to adolescents brings in different challenges. Although, they are definitely capable of self-administering drugs; incomplete understanding and altered perceptions regarding disease process, need for treatment and health maintenance, and defiant behavior can lead to disruption of therapeutic schedules. Education combined with periodic reinforcement of advice and vigilance can help minimize and eliminate these disruptions.

**Off-label and extemporaneous drug use** For several decades, the society, regulators and pharmaceutical industry have been reluctant to conduct clinical trials in children. Hence, the drugs get marketed for use in adults. However, when an indication exists for use of drugs in children; the health-care providers are required to prescribe these drugs although data regarding the efficacy, dose, dose regimen and safety in children have not been generated. This use is called as off-label or off-license use; and given the complexity of pharmacokinetic changes such prescriptions have the potential of causing harm. On the other hand, it is also unethical not to prescribe an available indicated drug, just because it is off-label. It is advisable that when an off-label drug is to be used, the use is rational, the caregiver bases his decision on evidence or guidelines, records the indication and dose used and parents are informed about such use. The regulators have woken up to the need for ensuring the availability of pediatric labeling information and have implemented initiatives, such as providing a financial benefit, including data from experiences to alter label (licensing information) and mandating industry to include children in clinical trials when the drug is likely to have a pediatric indication.

The other challenge faced by children is the non-availability of appropriate liquid formulations. Neonates, infants and young children cannot swallow tablets and when tablets and capsules are split for providing the drug, there is always a possibility of the child receiving an inaccurate dose raising the prospect of undertreatment (ineffective therapy) or overdosing (toxicity).

**Adverse drug reactions (ADRs)** These are defined as a noxious, unintended responses to a drug that occur at doses normally used in man for prophylaxis, diagnosis or therapy of disease or for modification of physiological function. Although, children suffer from ADRs similar to those in adults, they could be different because of differences in pharmacokinetics, pharmacodynamics, or age-related alterations in the maturation of systems. In addition, newborn babies and infants can get affected due to drugs that they received transplacentally during the fetal period or through breastfeeding. As the ADRs in infants and children could be different from adults in terms of frequency and manifestations, health-care providers need to be more alert in diagnosing them (**Box 1**).

#### BOX 1 List of some adverse drug reactions that are common in or unique to children

- Aspirin-associated Reye syndrome
- Chronic corticosteroid therapy inhibiting growth
- Serum sickness-like reaction associated with cefaclor
- Tetracyclines associated with staining of developing enamel
- Lamotrigine-induced cutaneous toxicity
- Dystonia associated with metoclopramide (more frequent than in adults)
- Valproate-associated hepatotoxicity in children aged less than 2 years
- Hepatotoxicity associated with nimesulide use
- Multiple anticonvulsant hypersensitivity syndrome associated with exposure to phenobarbitone, phenytoin and carbamazepine.

**Drugs and breastfeeding** Virtually every drug that enters maternal circulation will appear in the breastmilk. However, such transfer is not always a harbinger of harm. As the breastmilk is slightly acidic, weak alkaline drugs that are lipid soluble and have low molecular weight are more easily transported into the breastmilk. In most instances, the drugs are not transported in pharmacological amounts; although hypersensitivity reactions can occur even with these lower doses in infants.

When a nursing mother is on medications, a three-way classification of drugs is useful. One group consists of drugs that are commonly prescribed to newborn babies and infants (e.g., ampicillin and gentamicin). If the mother is on any of these drugs, there is hardly any concern. The second group consists of drugs that are prescribed to newborns and infants, but for very limited number of indications and with great caution. If the maternal drug belongs to this group, an acceptable alternative needs to be looked for and if not available; the risks and benefits of continued breastfeeding need to be assessed. If it is decided to continue with breastfeeding, the mother can be given the lowest possible dose for the shortest period of time and schedule of drug administration and breastfeeding can be adjusted so that drug exposure can be minimized. The third category of drugs includes those (such as antimetabolites, ergotamine and lithium) that are never given to neonates and appear in the breastmilk in significant amounts. If such therapy is necessary, breastfeeding would be contraindicated.

**Pharmacogenetics and personalized therapy** Pharmacogenetics has underlined the role of human genes in defining the pharmacokinetics and drug responses in individuals. This would make personalized care (wherein drugs would be selected on the basis of genetic profile of an individual patient) possible. Children would derive significant benefits in terms of improved pharmacotherapeutics only if technology is also employed to determine the changing patterns of gene expression that have bearing on pharmacokinetics and pharmacodynamics through the pediatric age-group.

### STEPS IN INITIATION OF THERAPY

It is usually believed that every illness should be treated. This principle of therapeutic enthusiasm is clearly appropriate in severe and life-threatening illnesses. It, however, does not apply to all clinical situations. Infants, children and adolescents have intrinsic recuperative capacities. Therefore, therapeutic intervention may not be required in many conditions. It should be borne in mind that drug therapy is not synonymous with good health-care. While initiating drug therapy, the treating doctor should undertake the following steps:

#### Reach an Initial Working Diagnosis

Reaching a provisional or working clinical diagnosis with the help of detailed history and examination constitutes an important

initial step in this process. Appropriate treatment can be started depending on the clinical status of the child. A critically ill child would require immediate therapy aimed at stabilization of vital signs. In this situation, it would not be appropriate to wait for the specific confirmation of the etiological agent. Therapy can be initiated taking into consideration the patient's age, likely etiological agent and the pattern of resistance likely to be encountered. The treatment can be changed subsequently on the basis of results of investigations and response to therapy.

### Define Therapeutic Objectives

In this step, the caregiver should specify what intends to be achieved through therapy and in what time interval. It might include symptomatic treatment, therapy directed amelioration or eradication of cause of illness and steps to prevent the occurrence of complications. For example, when the patient presents with fever and vomiting and is diagnosed to have typhoid fever, therapeutic objectives would include symptomatic relief (control of fever and vomiting), and eradication of the infectious agent (with anti-salmonella antimicrobial agent).

### Assess Effectiveness of Therapy

Comparative efficacy of different therapeutic regimens should be assessed. There is hardly any therapeutic regimen that is completely effective in all cases. Efficacy is dependent on several factors, which include patient's own defenses, drug's pharmacokinetic properties and stage of illness.

### Assess Risk to the Patient

Every effective drug has adverse effects. This is the second sieve (after efficacy) in the process of selecting suitable drug.

### Plan Strategies to Ensure Compliance

As adults take the responsibility of administering drugs to infants and children at home, the caregiver must explain to them the importance of administering the drug, the symptoms it would help control or the manifestations that it might ameliorate and when this is expected to happen, and the importance of completing the course. However, infants and young children are unlikely to ingest drugs that are unpalatable or have unpleasant smell. Thus, the doctor should be familiar with the available preparations, their flavors and unpleasant characteristics.

### Consider Costs Involved

Cost of therapy is a major determinant. However, this consideration should come after drugs are shortlisted on the basis of efficacy and safety. If a therapy is selected just because it is least expensive, the ultimate cost of therapy is likely to be higher as it is likely to prove inefficacious in many patients; who will then require a course of another effective drug. Costs could be reduced by using the appropriate formulation (avoiding injections when oral medications would suffice) and prescribing good quality generic drugs in preference to the branded ones. When time-honored inexpensive but effective medications are available, one should not push the parents to buy newer drugs that are usually more expensive.

### Enquire about Previous Experience

The treating physician should inquire about what has worked or failed in the child in the past. This should include questions about allergy, side effects and problems with compliance. Obviously, if a child has had an allergic reaction or serious side effects, the physician should avoid exposing the child to the same drug, again.

## PREScribing DRUGS FOR CHILDREN: PRACTICAL SUGGESTIONS

The following issues need to be kept in mind while prescribing drugs to children:

- Prescribe drugs only when required. Consider benefits, potential risks and costs of therapy. Monitor for response and undesirable events. Review therapy based on clinical and laboratory data.
- It is necessary to keep abreast with the advances in the medical field, especially those related to diagnostics and therapeutics. It is unwise to rush to prescribe new drugs just because they are recently discovered. Do not succumb to pressures of prescribing newly marketed drugs, unless a clear indication exists. Therapy should continue to be based on information, experience and judgment. Prescribe minimum number of appropriate, inexpensive drugs of good quality, one is familiar with.
- Write prescriptions clearly and legibly. State the name of the drug, preparation, dose, frequency and duration of treatment. Sign the paper prescription. It is desirable to provide the prescriber's contact details. Adhere to all legal requirements.
- To ensure compliance, explain the nature of the disease and the likely benefits to be obtained from the therapy to the parents. Provide clear written instructions to avoid misinterpretation. Clarify regarding drugs that need to be stopped after the child becomes asymptomatic and those that need to be given for a predetermined duration.
- Consult product insert guidelines or standard pediatric textbooks while prescribing drug doses.
- Prescribe medications for a complete course in appropriate formulations.
- *Direct parents to discard all remaining doses* This avoids accidental poisoning or improper self-medication at a later date.
- Explain the adverse effects of the drug. Explain the need for periodical clinical and/or laboratory monitoring. Instruct them to report an unexpected untoward event.
- Drug combinations should be used only when they are combined in the right and proportionate doses and when they are required to be administered at similar frequencies during the day (For example, amoxicillin plus clavulanic acid combination).

### IN A NUTSHELL

1. The pharmacokinetic profile of drugs is dissimilar in adults and children because of differences in distribution of drugs and absorptive, metabolic and elimination capabilities of children.
2. Various processes concerned with handling of drugs mature at different age.
3. Determination of dose and dosage frequency is a complex process, as several age- and maturity-related factors play a role. Hence, pediatric dosages should not be derived only on the basis of proportional reduction of adult doses.
4. Making a working diagnosis, enlisting therapeutic objectives, assessing comparative efficacy and safety of drugs, taking steps to enhance compliance, considering expenses of therapy and reviewing previous experiences are important steps while initiating drug therapy.
5. Monitor patient for effectiveness of therapy and look for untoward and unexpected events. The adverse drug reactions in children could be different from those in adults.

## Chapter 6.2

# Administration of Medications

Jeeson C Unni

This chapter discusses the various challenges faced while administering drugs to neonates, infants and children. For example, children need different types of formulations as compared to adults. Similarly, the way oral drugs can be administered in adults is quite different from that in children. Even pediatric population does not represent a homogeneous population. Infants require drops while young children require liquids and dispersible tablets and adolescents can be expected to take tablets and capsules. Much more care is required to be taken while administering intravenous (IV) fluids to neonates and infants, as they require smaller volumes of fluids to be given over longer durations.

## ISSUES REGARDING MEDICATIONS FOR CHILDREN

- Administering oral liquid medications to infants and young children is a challenge and the doctor should educate the caregiver in this regard.
- Doctors should clearly explain the indication dose and frequency of administration of each and every prescribed drug. It is also worthwhile explaining the time it might take for clinical response to appear. This would help scale down the parental expectations to realistic levels and would enhance compliance. In addition to the expected drug effect, the caregivers should educate guardians about the side effects.
- Children are extremely choosy about taste and recognize even minor alterations in taste when a medicine is mixed in food for administration.
- Forcing a medicine down the throat of an angry and reluctant child heightens the child's resistance to have any medicine.
- Formulations which are not appealing to children (e.g., due to initial bad taste, its odor or color) also add to child's reluctance. Religious, cultural, local and personal beliefs are often important determinants of medication acceptance.
- Nonavailability of sugar-free liquid/dispersible medicines in child prone to caries.

A pediatrician should be able to tackle each of these aforementioned issues. Reinforcement and elaboration of the physician's instructions by the pharmacist and other members of the health-care team is important. Proper education of the parents, grandparents and the adolescent child regarding the prescribed medications including need to report red flag signs may improve compliance, increase possibility of reporting concerns during treatment and decrease chances of discontinuation of therapy.

## ROUTES OF ADMINISTRATION

Medicines vary in form and are given by different routes.

- *By mouth*
  - *Liquid* Solutions, suspensions, syrups, elixirs, emulsions and oils
  - *Solid* Tablets, capsules, granules and lozenges
- *Inhaled* Metered-dose inhalers (MDI), powder devices and compressed air nebulizers
- *Into the ear* Solutions, suspensions, drops and ointments
- *Into the eye* Solutions, suspensions, drops and ointments
- *Into the nose* Solutions, suspensions, drops, ointments and sprays

- *On the skin* Solutions, suspensions, drops, ointments, sprays, creams, lotions, pastes, powders, shampoos and soaps
- *In the mouth* Lozenges, chewing gum and sublingual tablets (rarely)
- *Injected* Water solutions, suspensions and oil in water emulsions, depending on the route—subcutaneous (SC), intramuscular (IM), IV, intrathecal or intraosseous (IO)
- *Into the rectum* Enema, suspensions, oils, suppositories and ointments.

## Oral Administration

### Liquids

Though a child less than 5 years of age would swallow or chew on solids, they cannot be depended upon to take tablets. Older children also often prefer liquids. Taste, as mentioned earlier, is a factor that determines compliance with liquid formulations. Taste (unpleasant or otherwise) may be masked by adding acceptable flavoring agent or by mixing them in foods or drinks that the child likes. There is always the possibility that a child could recognize the change in taste of the foodstuff thus served and refuse any further feeds thinking the medicine would be added again. The dosage and absorption of medications may also be affected when it is mixed with food. It is important to check literature including drug monographs to ensure that mixing with food does not affect absorption/bioavailability of the drug and advice accordingly. As a general rule, it is advisable to avoid mixing drugs in feeding bottles.

Excipients are added to liquid medications to provide stability and taste. Preparations containing sugar, salt and alcohol need to be identified. Permissible alcohol content in medication intended for adults and children less than 12 years, 6–12 years and more than 6 years is 10%, 5% and 0.5%, respectively. Sugar-free preparations are preferable. The amount of lactose in most medications is too small to produce any symptoms in those with primary or secondary disaccharidase deficiency. Nevertheless, the lactose-containing preparations need to be administered cautiously to children with severe lactose intolerance. The child may be occasionally sensitive to oils used as emulsifiers. Propylene glycol is generally considered safe but large amounts can cause lactic acidosis, if its elimination is impaired, e.g., in renal failure, in neonates and young children, and in slow metabolizers. It may interact with metronidazole.

Teaspoon size varies and therefore it is not a reliable measure of the desired quantity of liquid medication that a child is prescribed. Time spent in explaining (and demonstrating, whenever possible) how a quantity may be measured using a dropper, plastic syringe or medicinal bottle cap with markings for different volumes, is time well spent.

Liquids are limited by their short shelf life. In addition, they are heavy and bulky requiring greater storage space in pharmacy and while transporting. Many liquid preparations also require refrigeration. Powders for suspension are affected by humidity and need to be mixed with sterile fluids.

### Tablets

Tablets are cheaper than most other preparations; one can carry them around easily; and they are stable. It is generally felt that children in the schoolgoing age can swallow tablets. However, there are exceptions to the rule and many are uncomfortable with swallowing tablets even till adolescence. A liquid *chaser* could follow immediately after the tablet is swallowed. Most tablets can be crushed and most capsules may be emptied to make a suspension in something acceptable to the child. But crushing certain tablets to mix them with food or water may change the rate or extent of drug absorption, e.g., drugs like lopinavir/ritonavir used in antiretroviral therapy. Crushing drugs with a narrow therapeutic index, such as levothyroxine, could also result in considerable variability

between doses. It is not advisable to break or crush slow-release or enteric-coated tablets. When cutting a tablet, it is necessary to follow specific instructions on the process, including the proper use of a tablet splitter. And whatever method is used to cut or crush a tablet, it is near to impossible to provide an accurate dose where small doses are required as in the neonate, infant or small sized toddler. Splitting tablets is easier when scored tablets are available. Tablets that *melt* on the tongue in a small amount of saliva or the tablets that can be dispersed in a small amount of liquid on a spoon, are easy to administer and ensure accurate dose provided their taste is acceptable. Sublingual administration of drugs is difficult in young children. It is definitely not advisable to open a capsule and administer the powder, if the reason for having a capsule formulation is to avoid its degradation or neutralization by gastric juices. Advances in pharmaceutical technology have resulted in the development of many different types of tablets, those that melt in the mouth; chewable and orodispersible tablets and films.

### Administration through a Feeding Tube

Children with feeding tubes in place, can be encouraged to take medicines by mouth. This may not be possible if, for example, the tube is in place because of a problem with swallowing or if the child is unconscious. Liquid medicines can be given via the tube, provided special precautions are taken to avoid the tube being blocked by the medicine. The liquid formulation should flow easily down the tube and the medicine should be *washed* through with warm water. If medicines are given to a newborn infant via a nasogastric tube, then sterile water must be used. Medicines may be mixed with enteric feeds provided the two are compatible. In general, continuous feeding should be discontinued for 15 minutes before giving a medicine down the tube, unless otherwise specified.

### Inhalational Route

For respiratory ailments, administering medicines through inhalation is the most logical method of delivering medicines directly to the lungs, the target organ. The dose required to achieve the necessary drug levels in the lungs is miniscule when this method is used and hence the side effects (both local and systemic) are also minimal. These advantages need to be explained to the caregivers and the adolescent patient, to ensure compliance.

The child needs to be provided information on various available devices and should be allowed to decide the device of her/his choice. Long-term compliance is poor in young children who are uncooperative and in those whose caregivers force the procedure on them.

The teaching of technique (using MDI, MDI with spacer, dry-powder inhalers) and good care of the devices are essential for success (**Box 1**). Regular review is necessary to ensure that the devices are functional and effective and to check if the child is using them in an appropriate way. Because products and delivery systems vary, it is important that the manufacturer's directions are followed precisely.

Nebulizers can be used in children of all ages. The child breathes an aerosol through a facemask or preferably, a mouthpiece. A mouthpiece gives better deposition. In acute asthma, oxygen and not air should be used as a driving gas while administering drugs such as salbutamol, terbutaline or ipratropium to minimize the possibility of exacerbating hypoxia.

Breath-activated inhalers do not require coordination but the child must be able to take a deep breath. MDI require a child to press and breathe in at the same time. Most school children cannot manage them and their use without spacers is not encouraged. A spacer should always be used if a corticosteroid is being administered via a MDI.

#### BOX 1 Administration of inhalational drugs

##### A. With metered-dose inhalers

- Remove the mouthpiece cover
- Shake the inhaler
- Breathe out as much air as is possible, gently
- Place the inhaler mouthpiece in the mouth between the teeth. Seal lips around it
- As the child begins breath in slowly through the mouth, press the canister and continue breathing. This coordination is vital for ensuring appropriate delivery of the drug
- Remove the inhaler from the mouth and hold breath for about 10 seconds
- Wait for at least 1 minute if another dose needs to be taken.

##### B. Metered-dose inhalers with spacer device

- Remove the mouthpiece cover
- Shake the inhaler
- Fix the mouthpiece of the inhaler in an upright position into the slot provided on the spacer
- Put the spacer mouthpiece between teeth without biting and close lips to form a good seal
- Breathe out gently through the nose
- Press the canister firmly once to instill the spray into the spacer
- Breathe through mouth, in and out, gently and slowly
- The inspiratory breath must be sufficient to visibly or audibly open the valve
- Remove the spacer from the mouth and hold the breath for 10 seconds or as long as comfortable
- Dismantle the assembly of spacer and metered-dose inhalers
- If an extra dose is required, wait for a minute and repeat the steps. Instilling two or more doses simultaneously results in droplets crash/colliding against each other and settling at the bottom of the spacer. These are then not available for inhalation
- Spacer should be cleaned weekly by washing. It should be allowed to dry and should not be wiped. It should be replaced annually.

##### C. Dry powder inhalers

- To use these correctly, children need to be able to take a good deep breath in, to draw the powder into the airways
- They need to be able to hold their breath and not to blow out first.

### Ophthalmic Preparations

Medicines meant for ophthalmic use should be kept sterile. An ophthalmic preparation should be discarded 28 days after it is opened as the probability of bacterial contamination is high beyond this period. The ideal is to drop the solution or squeeze the ointment into a gully formed by pressure of a finger on the lower lid. Tilt the head back or lie the child down and direct the gaze of the child upward. Avoid touching the eye. Alternatively, lay the infant on his or her back, drop the solution or ointment into the corner, wait until the infant's eyes open and then gently mop away the excess. In neonates and infants, it is more appropriate to instill into the inner angle of the open eye. Gentle finger pressure on the inner corner of the eye to occlude the tear duct enhances the effect of the eye drop. Massage the ointment into the upper and lower conjunctival sacs with finger massage on the upper and lower lids. Eye ointment may be applied either at night (if eye drops used during the day) or 3–4 times daily (if eye ointment used alone).

One drop is all that is needed; instillation of more than one drop at a time should be discouraged because it may result in an overflow and wastage of medicine or increase the probability of occurrence of systemic side effects, and results in an overflow. A small amount of eye ointment is applied similarly; the ointment melts rapidly and blinking helps to spread it. If multiple drugs are to be instilled, to avoid dilution and overflow it is recommended to

maintain an interval of at least 5 minutes between the two; interval may be extended for eye drops with a prolonged contact time, such as gels and suspensions. Application of an eye ointment should follow that of eye drops, if both need to be administered at the same time.

### Contact Lenses and Ophthalmic Preparations

Drugs and preservatives in eye preparations can accumulate in hydrogel lenses and can cause adverse reactions. Therefore, unless medically indicated, the lenses should be removed before instillation of the eye preparation and not worn during the period of treatment. Eye drops may, however, be instilled while patients are wearing rigid corneal contact lenses. Ointment preparations should never be used in conjunction with contact lens wear; oily eye drops should also be avoided.

### Aural Medications

These are used to treat conditions of the external auditory canal, which is not sterile. The method of administering medications into the external auditory canal is described in **Box 2**.

### Delivering into the Nostrils

The lining of the nose is very vascular, so the intranasal route offers an alternative to an injection to achieve a systemic effect. This is the chosen route for some peptides (e.g., desmopressin). Currently however, most nose drops are given for the treatment of local conditions. Some children might not like having liquid squirted into the nose. Because the nasal passage connects to the throat, there is a tendency for the saline solution to drip down the back of the throat, giving rise to a bad taste. The method of administration of intranasal drops and sprays is described in **Box 3**.

### Topical Application

Topical applications are mainly used for treating disorders of the skin. However, it can be used as a route for drugs with systemic effect, and it must always be remembered that topical drugs may cause systemic toxicity, particularly if applied to damaged skin or to preterm infants. Generally the skin is left exposed, but a wet dressing may facilitate absorption, and a dry dressing may be used for protection.

*Creams* are a semisolid emulsion with equal amounts of oil and water. They are easy to spread and wash off with water. The active ingredient gets well absorbed and creams promote hydration of the skin. Lotions are thinner than creams and feel very light on the skin. The ingredients in lotions are absorbed very quickly. They are preferred for hairy areas. *Ointments* are 80% oil and 20% water. Although the ingredients are not absorbed well quickly, the ointment remains in contact with skin for longer periods due to its occlusive properties. In this manner, ointments promote absorption of the ingredients. This makes them more potent than when packaged as cream or lotion. *Gels* are emulsions that contain oil-in-water. They usually have an alcohol base. They dry into a thin, greaseless, nonstaining film. They may be used on hairy areas and when large areas need to be treated. Because they dry the skin they may be used for those with oily skin. *Pastes* are a mixture of powder and ointment (e.g., zinc oxide 20% paste)—powder improves porosity (breathability).

It is important therefore to keep in mind the type of vehicle used for topical medications. An occlusive vehicle like an ointment enhances penetration of the active ingredient and improves efficacy. The vehicle itself may have a cooling, drying, emollient, or protective action. It can also cause side effects by being excessively drying or occlusive. The type of preparation used can be determined

#### BOX 2 Administration of aural medications

- Warm the bottle of ear drops if the weather or the room is cold. Rub the bottle back and forth between the palms to let the warmth thus generated heat the bottle
- Place the head on one side
- Pull the ear back and down for the infant and back and up for the older child
- Place the number of drops prescribed in the ear so that they hit the side of the ear canal and roll into the ear
- Wipe any excess drops off the outside of the ear
- Have the child remain with her head tilted or lying on her side for a few minutes to allow the drops to flow all the way into the ear
- Do not put the drops directly into the ear canal without allowing it to hit the side as this could cause pain or dizziness
- Gentle massage immediately in front of the ear helps the drops to descend into the ear and relax the child.

#### BOX 3 Administration of medications by nasal route

##### Intranasal Administration

##### A. Administration of nasal drops

- Lay the child on his or her back with neck extended
- Instill the prescribed drops
- Tilt head forward

##### B. Administering nasal spray to infants

- Make sure to have a nasal spray, small towel, and tissues on hand
- Lay the baby on the lap, with head resting gently on the knees and feet pointed toward caregiver's waist
- Gently spray one or two nasal drops in one nostril and allow a few seconds for the solution to moisturize the nasal passage and loosen the excess mucus
- Use a tissue to wipe any drainage from the nose or face
- Avoid touching the applicator to your baby's nose to prevent the spread of germs.

##### C. Administering nasal spray to older child

- Hold child in sitting position and support him with one arm. Use the other arm to squirt the nasal drops
- Tilt the child's head back slightly. As child takes in a breath, administer one saline nasal dose to each nostril
- After the spray has had time to moisten the nasal passage and loosen excess mucus, help the child gently blow his nose to remove mucus
- Avoid touching the applicator to your baby's nose to prevent the spread of germs.

by the type and site of lesions. For example, greasy ointments should not be preferred for acute weepy dermatitis, and powder in the paste is useful when treating diaper rash. Gel or lotion should be preferred for hairy areas. The irritation or sensitization potential should also be taken into consideration. Generally, ointments and water-in-oil creams are less irritating, while gels are irritating. Ointments do not contain preservatives or emulsifiers, and can be preferred when allergy to preservatives is a concern.

### Parenteral Administration

Drugs may be injected into most of the body spaces. The drugs must be sterile and pyrogen-free. The skin may be washed and then cleaned with antiseptic (70% isopropyl alcohol) or in children not sensitive to iodine, with an iodophor. If alcohol is not allowed to evaporate, this may add to the pain of injection. A topical anesthetic cream may also be used. Neither is common practice when insulin is self-administered or vaccines are given. Children less than 5 years of age should be held firmly; older children should be well-supported but not overpowered; those over 12 years of age, like many adults, may be frightened of needles and their feelings need to be recognized and addressed. Many parents are a great

help and will assist with restraining and comforting their child, but others find the experience upsetting and should not be forced to hold their child during the procedure, but encouraged to comfort afterward. Adolescents need to be told to lie down for a while after a parenteral drug administration to avoid possible vasovagal syncope (e.g., human papillomavirus vaccine).

### Subcutaneous Route

Small volumes (under 2 mL) of isotonic solutions are usually given into the SC tissue using short needles with narrow bore and regular bevel. The SC route is used for insulin self-injection. There is a possibility of fat atrophy or hypertrophy occurring. This can be minimized by rotating the injection sites, over the outer aspect of the upper arm, the anterior or lateral thigh, and the abdomen. In thinner children, it may help to pick-up the skin gently between the fingers to create a pocket in which to inject vertically.

### Intramuscular Route

Most drugs can be injected into the muscle. However, the IM route should be avoided, whenever possible. In practice, the route is used for administering concentrated and irritating solutions, which may cause local pain if injected subcutaneously. Volumes of 1–2 mL can be administered through the IM route in infants, while older and bigger children can receive volumes up to 5 mL. The shorter and the narrower the needle, the less pain it will cause. Some draw up the fluid with one needle and inject with another, to avoid the solution on the wet needle irritating the needle track. Using a single needle saves time and for most drugs leads to no extra reaction. Before injecting the solution, the plunger should be slightly withdrawn to check whether the needle has entered a blood vessel. If blood is withdrawn, another site must be chosen. IM injections should not be given to children on anticoagulants or to those with thrombocytopenia. As IM injections can damage muscles and leave deep scars, injection sites should be regularly inspected, particularly in the immobile and very sick.

### Intravenous Route

This route is generally chosen when a medicine cannot be given by mouth and one requires faster onset of action. Reliable access, often a central vein, should be used for children whose treatment involves irritant or inotropic drugs or who need to receive the medicine over a long period. The IV may be given as intermittent bolus, continuous or intermittent infusion. IV administration is used for administering intravenous fluids (maintenance fluids and for correction of fluid, electrolyte and acid-base disturbances), blood and blood products and medications.

Administration of IV drugs and fluids at slower rates and in small volumes required in neonates, infants and small children requires special equipment. The micro-drip set is useful in these situations as the narrow tubing produces smaller drops enabling precise adjustment of slow flow rates. Infusion pumps can administer fluids at rates as little as 0.1 mL per hour; administer injections every minute or as repeated boluses; and amounts that vary at different times of the day. Fluids can be pumped in at high pressures and hence these pumps may be used for giving accurate amounts of fluids via SC or epidural routes.

### Per-rectal Administration

This route is used when drugs cannot be given orally or intravenously or when a local effect is desired. Presence of diarrhea, impacted feces and fissure *in ano* are contraindications to the use of this route. The child should be lying on his side, with legs curled

up in a fetal position. With babies, it is possible to administer drugs per-rectally by lifting her legs and flexing the knees (as for changing a nappy). The suppository should be gently inserted into the anus, just beyond the anal sphincter. It may be necessary to hold the buttocks together for several minutes to prevent the immediate expulsion of the suppository.

### Intraosseous Route

Intraosseous access is resorted to, if vascular access is not rapidly achieved in any infant or child requiring IV drugs or fluids, especially in a life-threatening emergency. Those trained in the procedure can achieve access successfully in around 80% of attempts, within 1–2 minutes. In infants and children, proximal tibia is the most commonly chosen site for IO catheter insertion. The recommended site is the flat area approximately 1–2 cm distal to the tibial tuberosity. The needle may be angled 10–15° caudally to avoid injury to the epiphyseal growth plate. Disadvantages of this route include extravasation and rarely osteomyelitis.

### Endotracheal Route

The endotracheal route may be used for administering drugs when IV or IO access is not achieved especially in a life-threatening or serious condition. Medications are absorbed through this route but the blood levels attained may not be equivalent to those produced by IV/IO administration. Further, for most drugs the optimal doses for endotracheal use are unknown. Drugs that can be given by this route include surfactant, lidocaine, epinephrine, atropine and naloxone.

## METHODS OF GIVING MEDICINES

Young children and infants who cannot understand will usually take medicine from someone they know and trust, a parent or the main caregiver. It is important that those who give medicines know about the medicine and how to give it. Occasionally, a medicine has to be disguised or masked with small quantities of food. Rarely, a child has to be restrained for the medicine to be administered. Then, especially, the child should be comforted and reassured. They must not be left with the impression that being given medicine is a punishment for being sick. The approach depends on the child's understanding and the circumstances:

- Under 2 years of age: Administration by parents if possible, using an approach which they believe is most likely to succeed.
- Two to five years old need a calm, gentle, firm and efficient approach after they have been told what is happening. Play and acting out may help them understand. Rewards and an acceptable *chaser* (drink) encourage further collaboration.
- Five to twelve years old also need encouragement, respect for their trust, and an explanation attuned to their understanding.
- Children over 12 years of age: At this age children must have a proper understanding of what is happening. They should be having a share in the decision-making process as well as the responsibility for adhering to the agreed plan. They must feel in control.

### Ensuring Safety of Medicines

Children and neonates are extremely vulnerable to harm due to errors while prescribing, administering and storing medicines. The doctors, parents and caregivers need to be extremely vigilant to ensure that children do not suffer from undue harm. All of them need to take coordinated steps to ensure this safety. Some of the steps are enlisted in **Box 4**.

**BOX 4 Steps to avoid undue harm during prescribing and administration of drugs to children***Doctors*

- Prescribe suitable formulation based on the child's age, development and ability
- Calculate doses diligently. Do not hesitate to use calculators. It is better to have another independent check
- Check the concentration of active ingredient in the formulation
- Prescribe oral medications in terms of mL and not in terms of teaspoon/tablespoons. The volume in spoons is highly variable
- Avoid the use of decimal points by prescribing in whole units, i.e., 100 µg rather than 0.1 mg
- If a decimal point is required, always use a leading zero, i.e., 0.5 mL
- Avoid using a trailing zero. For example do not write 5 mg as 5.0 mg. The latter can lead to a tenfold error
- Remember to account for any administration issues such as displacement volume for IV medicines, the correct diluent and administration method
- Provide complete information regarding the dose, frequency, side effects, possibility of response and action to be taken if any untoward event is noticed
- Instruct parents/caregivers regarding appropriate storage of medicines, keeping them away from children and discarding them
- Ensure that parents/caregivers have understood the instructions. Encourage them to get doubts clarified.

*Parents/caregivers*

- While buying drugs, ensure that the preparation is the same as prescribed. Check for the expiry date
- Follow instructions regarding administration, storage and discarding of medicines provided diligently
- If something is not understood, do not hesitate to get doubts clarified
- If there is an unexpected event, contact the doctor. It could be due to progression of disease or due to an unrelated event. It could also be due to a side effect of the drug.

*General*

- Report adverse events
- Advocacy for the conduct of clinical trials in children and for availability of formulations appropriate for children.

**IN A NUTSHELL**

1. Administering medicines to children is a challenge and requires special attention. It needs the cooperation of the child and understanding of the parents/caregivers.
2. Depending upon their age and developmental abilities, children require different types of oral formulations: drops, syrups, suspensions and dispersible tablets. Tablets and capsules are suitable for older children.
3. Lack of appropriate formulations compromises the right of children to safe medicines.
4. Caregivers need to be informed about the medicines and way to administer them. It is advisable to demonstrate the method of measuring actual volume of oral liquid preparations to them to avoid under or overdosing.
5. Additional specific equipment may be necessary to ensure that correct dose is administered. For administering aerosol medicines, young children might need a spacer device in addition to a MDI. To ensure that the correct volume is delivered while providing IV fluids and drugs, doctor may have to use syringe infusion pump. The syringe infusion pump allows measured delivery of small volumes over a longer time period.
6. Well-coordinated actions by doctors, pharmacists and parents are required to ensure that children receive their medicines in the right amount, at the right frequency, for the right duration without exposing them to undue risks.

# PART III Intensive Care and Emergencies

## Section 7 ACUTELY ILL CHILD AND RESUSCITATION

Section Editor Rakesh Lodha

### Chapter 7.1

### Assessment and Triage

Jayashree M, Sunit Singh

Most cardiac arrests in infants and children result from progressive respiratory failure, shock, or both. Sometimes, they can occur due to sudden cardiac events such as arrhythmia. The outcome of out-of-hospital cardiac arrest despite optimal resuscitation is only 4–13%. Therefore, quick recognition and timely intervention in respiratory and/or circulatory failure is paramount to prevent progression to cardiac arrest. The biological response to any initiating illness, e.g., trauma, infection, surgery, burns, etc., involves activation of immune system that further triggers an inflammatory cascade, which if untreated can spiral into sequential organ failure called the *physiological domino effect*. The longer the process, the more advanced and irreversible the physiological derangements become, resulting in a high mortality. Therefore, the key to emergency management is to identify and stabilize the physiological or functional impairments irrespective of whatever may be the primary etiology.

Triage refers to assessment of a patient in the *emergency room* with a view to define urgency of care and priorities in management, and also helping in the rational allocation of limited resources when the demand exceeds the availability. This system is a structured framework within which a patient is classified according to the acuity and severity of illness. Those who need acute care in the *emergency department* (ED), are attended to immediately in order of priority while those needing less acute care wait in the triage room. There are many international triage systems devised for acute care in emergency departments such as Emergency Triage and Treatment (ETAT) guidelines, Emergency Severity Index (ESI), Canadian Triage and Acuity System (CTAS) and the Australian Triage Scale. Goals of triage are summarized in **Box 1**.

#### BOX 1 Goals of Triage System

- To rapidly assess and identify children with life-threatening illness
- To determine appropriate cause and initiate timely interventions
- Order immediate investigations and procedures as per the need
- To provide safe and quality care to patients
- To perform ongoing assessments, keeping in mind the dynamicity of illness and progression
- To utilize the limited resources in an efficient manner.

### PEDIATRIC TRIAGE

The rules of “Rights” have to be followed in every patient who presents to the emergency: *Get the right patient to the right provider, in the right moment of time, to receive the right care, to achieve the right outcome.*

The pediatric triage assessment is a rapid 3–5 min clinical evaluation of a child with an aim to determine the severity of illness by means of subjective and objective parameters. Also, it is particularly important to triage each child according to the age, symptomatology and acuity of illness. What is assigned a high level of acuity differs with age and associated symptoms and signs, e.g., abdominal pain or fever less than 39°C in older child may be non urgent but an emergency for a one month old infant. Once the patients are triaged, they are classified into 5 levels of category (discussed here) and prioritized accordingly.

### Triage Assessment

Triage evaluation can be completed in an organized and systematic manner using the general assessment, i.e., Pediatric Assessment Triangle (PAT) and primary assessment (ABCDE approach). This assessment is different from diagnostic evaluation and is based and modified from Pediatric Advanced Life Support (PALS) guidelines. The objective is to identify anatomical or functional abnormality, its severity, and to plan and guide initial emergency treatment and stabilization. The assessment and treatment always go hand in hand.

### General Assessment

The PAT (**Fig. 1**) comprises of the immediate visual and auditory impression of a sick child who is wheeled into an ER based on the triad of appearance, breathing and circulation. The process is rapid and hardly takes 30–40s at the end of which the provider is able to identify children with acute life-threatening problems requiring

Figure 1 Pediatric assessment triangle

**Figure 2** Pediatric assessment pentagon

immediate life-saving interventions, e.g., a child who is brought gasping.

**Appearance** Muscle tone, interaction, consolability, look/gaze or speech/cry are assessed.

**Work of breathing** Increased work of breathing (nasal flaring, retractions), decreased or absent efforts or abnormal sounds (wheeze, grunt, and stridor).

**Circulation** Abnormal skin color (pale or cyanosed) or bleeding.

Based on PAT assessment, patient's illness is categorized as either stable or unstable. The unstable ones are further classified into life-threatening and non-life-threatening. Patients in the former category, e.g., cardiac arrest, cardiorespiratory failure, hypotensive shock, deep coma, severe stridor, etc., need immediate treatment or resuscitation before proceeding to primary assessment.

## Primary Assessment

The primary assessment [assessment pentagon (**Fig. 2**)] involves a more detailed physical examination/assessment of airway (**A**), breathing (**B**), circulation (**C**), neurologic abnormalities (**D**) and head-to-toe examination (**Exposure**). Primary assessment should be completed in 1–3 minutes. Besides clinical parameters, primary assessment also involves recording of SpO<sub>2</sub>, ECG and blood glucose.

## Airway

The anatomical part of respiratory tract which acts as a conduit for carrying atmospheric air to lungs but does not participate in gas exchange is called the airway. The goal is to determine the patency of airway which can be determined by *look, listen* and *feel* maneuvers.

*Look:* for chest rise.

*Listen:* for breath sounds and air movement.

*Feel:* the movement of air at the nose and mouth.

**Status classification** Normal or obstructed airway. Signs that suggest airway obstruction are inability to speak, a silent cough, breathing difficulty, poor chest rise, gurgling noises, pooling of secretions or paradoxical chest movements.

**Stabilization** Some airway problems respond to simple maneuvers such as positioning (chin-lift head-tilt) or suction while some require adjuncts such as oropharyngeal airway, endotracheal tubes or laryngeal mask airway to maintain patency. In suspected cervical spine injuries, the airway should be opened with the jaw thrust maneuver.

## Breathing

The goal is to determine the adequacy of gas exchange (oxygenation and ventilation). The assessment of breathing includes an evaluation of the respiratory rate and effort, lung sounds, and pulse oximetry. Normal respiratory rates are age dependent (**Table 1**) and hence respiratory rates more or slower than normal for age are defined as tachypnea and bradypnea, respectively. Apnea is defined as a complete cessation of breathing for 20 sec or more.

Increased work of breathing (WOB) manifests in the form of nasal flaring, retractions, accessory muscle use, or irregular respirations. The adequacy of tidal ventilation is determined by the chest wall excursion, and auscultation of air movement. Abnormal lung sounds include stridor, grunting, gurgling, wheezing, and crackles. O<sub>2</sub> saturation more than 94% at room air is surrogate for adequate oxygenation.

**Status classification** Based on the above assessment, a child's respiratory status can be classified into two severity groups: 1. Respiratory distress and 2. Respiratory failure. The following combinations can give a reasonable idea about the level of respiratory problem:

Retractions + stridor = Upper airway obstruction

Retractions + wheeze = Lower airway obstruction

Retraction + Grunt/labored breathing + crepitations = Parenchymal disease

Increased rates without recessions = Acidosis or neurogenic hyperventilation

Paradoxical breathing/see-saw breathing = Neuromuscular weakness

**Stabilization** O<sub>2</sub> saturations less than 92% qualifies for hypoxemia and warrant oxygen support through nasal prongs, facemask, partial re-breathing or non-rebreathing mask provided, the patient is breathing spontaneously. Patients having hypoxemia with poor respiratory efforts, require assisted breathing with bag and mask or bag and tube immediately.

**Table 1** Normal respiratory rates (breath/min), according to age

Age range Years	Neonates	0–1	1–2	2–3	3–4	4–5	5–6	6–12	12–13	13–18
APLS	30–40	30–40	25–35	25–30	25–30	25–30	20–25	20–25	15–20	15–20

### Circulation

The goal is to determine the adequacy of cardiac output (pre-load, myocardial contractility and afterload) and tissue perfusion. The assessment of cardiovascular function is basically divided into direct parameters which include heart rate and rhythm, peripheral and central pulses, blood pressure, and capillary refill time and indirect parameters which indicate adequacy of end organ perfusion such as skin color and temperature, urine output and level of consciousness. Heart rate is also age dependent as shown in **Table 2**. Normally, the rate will be slower in a sleeping or an athletic child. Labeling as tachycardia or bradycardia will depend on age-based cut-offs.

Similarly, blood pressures also vary according to age (**Table 3**). Hypotension is defined as BP below the fifth percentile for age. In children who are not hypotensive, an observed fall of 10 mm Hg in systemic blood pressure from baseline should prompt careful evaluations.

The heart rhythm should always be determined during circulatory assessment by attaching to a monitor or taking a three-lead ECG so as to rule out or rule in rhythm disturbance as a cause for circulatory instability. The important dysrhythmias to recognize are supraventricular tachycardia, ventricular fibrillation, ventricular tachycardia, pulseless electrical activity (PEA) and asystole. Once recognized, appropriate interventions need to be initiated. Adequacy of end organ perfusion can be

determined by measuring the urine output which is normally maintained at 1 mL/kg/hour.

**Status classification** Based on the above assessment the severity of child's circulatory status can be classified into two groups: 1. Compensated shock (poor perfusion with maintained BP); 2. Hypotensive shock (poor perfusion with less than 5th centile BP). The mechanism of shock may be one or combination of hypovolemic, distributive and cardiogenic.

**Stabilization** O<sub>2</sub> with a non re-breathing mask (FiO<sub>2</sub> 100%) should be started in all children with shock. The first priority in shock stabilization is to optimize the preload with help of isotonic fluids (20 mL/kg of isotonic saline). The rapidity of administration is determined by the severity of shock. Fluid refractory shock (after 40–60 mL/kg) is treated with vasoactives. First dose of antibiotics should be given in suspected septic shock. Early inotropes should be initiated in cardiogenic shock.

### Disability

It involves a quick evaluation of cortical and brainstem functions. Standard evaluation includes the level of consciousness using an AVPU scale (Awake, Voice, Pain, Unresponsive), or Glasgow Coma Score (GCS), muscle tone, pupillary response to light, motor activity and symmetry/asymmetry of movements. A change of at least 2 points in the GCS score from one assessment to the next indicates a clinically important change in neurological status.

**Status classification** Based on the above assessment the disability status can be classified into two groups: 1. Primary brain dysfunction (e.g. encephalitis, meningitis, acute stroke or traumatic brain injury); and 2. Systemic dysfunction (altered sensorium secondary to systemic changes such as shock, sepsis, hypoxia, etc.).

### Exposure

Examine for evidence of trauma, unusual markings of abuse, rashes, bleeds and core temperature.

At the end of the primary assessment, patient's physiological status is classified as; stable, respiratory distress or respiratory failure, shock compensated or hypotensive, primary brain/systemic dysfunction, cardiorespiratory failure or cardiorespiratory arrest and further triaged into 5 levels.

### Triage Classification

Patients' illness severity can be triaged into 5 levels depending on the physiological abnormalities (**Table 4**).

**Table 3** Normal systolic and diastolic blood pressures according to age

Age	Systolic BP (mm Hg)	Diastolic BP (mm Hg)
0 day	60–76	30–45
1–4 days	67–84	35–53
1 month	73–94	36–56
3 months	78–103	44–65
6 months	82–105	46–68
1 year	67–104	20–60
2 years	70–106	25–65
7 years	79–115	38–78
15 years	93–131	45–85

Females have slightly lower systolic blood pressures, and higher diastolic blood pressures than males of the same age.

(Adapted from Fourth Report on the diagnosis, evaluation and treatment of high blood pressure in children and adolescents: NHLBI; May 2004)

**Table 4** Triage classification

<i>Triage Level</i>	<i>Acuity</i>	<i>Description</i>	<i>Target time to Treatment and Reassessment</i>	<i>Examples</i>	<i>Remarks</i>
Level 1	Resuscitation	Patient with life-threatening disease or injury requiring immediate treatment	Immediate and continuous (1–5 minutes)	Cardiac arrest, seizure, unresponsive, airway obstruction, hypothermia, coma, Glasgow Coma Score (GCS) < 10, major burns, severe trauma, severe respiratory distress, shock	Need continuous assessment and intervention to maintain physiological stability
Level 2	Emergent	Patient with significant health problems that could become life threatening or disabling	15 minutes	Moderate respiratory distress, stridor, GCS < 13 Severe dehydration, febrile child < 3 months old and temperature > 38°C, inhalation or ingestion of toxic substance, acute bleeding, purpuric rash, burns > 10%, abdominal pain with vomiting/diarrhea or abnormal vitals	Any infant/child who require multiple interventions to prevent further deterioration
Level 3	Urgent	Patient with significant health problems that are not immediately life-threatening or disabling	30 minutes	Alert, oriented, with minor alteration in vitals Febrile child > 3 months old with temperature > 38.5°C, minor head injury	Level 3 patients need carefully planned reassessments while awaiting care, since critical illness may present with common symptoms and may evolve rapidly
Level 4	Less urgent	Patient with stable health conditions; to be evaluated in the ED	1 hour	Diarrhea with no dehydration, lacerations, pain, sore throat	
Level 5	Non-urgent	Patient with stable health conditions; to be evaluated in ED/OPD	2 hours	Afebrile, alert, well oriented, euhydrated, normal vitals	These patients may be referred to other areas of hospital for management

(Adapted from Canadian pediatric triage and acuity scale)

Abbreviations: ED, emergency department; OPD, outpatient department.

### IN A NUTSHELL

1. The key to emergency management is to identify and stabilize the physiological or functional impairments irrespective of the primary etiology.
2. Triage refers to rapid assessment of children with the objective to define urgency and prioritize management.
3. A patient is classified according to the acuity and severity of illness. Those who need acute care in the emergency department (ED) are attended to immediately while those needing less acute care wait in the triage room.
4. The assessments are systematic and organized using PAT triangle and ABCDE pentagon.
5. Patient's illness severity is triaged into 5 levels of acuity based on physiological abnormalities: Resuscitation, Emergent care, Urgent care, less urgent and non-urgent care.
6. Patients in cardiac arrest, cardiorespiratory failure, hypotensive shock, deep coma, and severe upper airway obstruction are categorized as life-threatening problems and resuscitated immediately.

## Chapter 7.2

# Cardiopulmonary Resuscitation

*Utpal Bhalala, Vijay Srinivasan*

Cardiac arrest (CA) in children is a global public health problem that tragically cuts short the life and potential of a child with important emotional and economic consequences to family and society at large. Modern cardiopulmonary resuscitation (CPR) was developed approximately 65 years ago by Kouwenhoven, Jude, Knickerbocker and Safar at the Johns Hopkins Medical Center in the USA. Subsequent advances in resuscitation science and coordinated emphasis on the science of education and implementation have substantially improved survival outcomes for pediatric CA, particularly for in-hospital CA. Certain groups of children (such as those who undergo cardiac surgery) are at much greater risk for CA but also have improved potential for good survival outcome. Unfortunately, good neurologic outcome and quality of life is frequently unattainable, especially following pediatric out-of-hospital CA. This chapter will review the etiology of pediatric CA (both in-hospital and out-of-hospital), mechanisms of blood flow during CA, techniques and quality of CPR, and post-resuscitation care that can save the lives of children and improve their subsequent quality of life.

## HISTORY

The problem of CA has occupied the minds of scientists and investigators over several millennia. Several methods to restart the heart have been described over centuries ranging from comical to dangerous, betraying a lack of understanding of cardiopulmonary physiology. The discovery of electricity greatly aided efforts to treat CA. The first successful case of open-chest defibrillation in humans was reported in 1947 by Beck. However, open-chest CPR is impractical for obvious reasons and can only be used in limited circumstances. In the 1950s, investigators observed that application of pressure to the sternum and sides of the chest resulted in increase in intra-arterial pressure. This sparked the discovery of chest compressions and resulted in the first instance of external compressions and defibrillation being employed in a 2-year-old child. Subsequently, this technique was employed successfully in over a 100 patients who experienced CA. Following these efforts, Safar incorporated oxygenation and ventilation with closed chest compressions, resulting in the birth of CPR as we know it. Over the last 65 years, significant advances in our knowledge of CA and science of CPR have enhanced the widespread use of this technique to save countless lives. Notably, national and regional resuscitation council societies [American Heart Association (AHA), Heart and Stroke Foundation of Canada, European Resuscitation Council, Australia and New Zealand Committee on Resuscitation, Resuscitation Councils of Southern Africa, Inter American Heart Foundation, and Resuscitation Council of Asia] have come together to coordinate efforts through the International Liaison Committee on Resuscitation to develop and revise guidelines for CPR every 5 years that are widely published in leading medical journals and available free of cost to health-care providers. This has hugely helped standardize the technique of CPR and enabled providers to speak a common language during detection of CA and delivery of CPR.

## EPIDEMIOLOGY

Estimates of pediatric CA and subsequent survival vary widely between different countries and regions across the world, largely due to limitation in reporting mechanisms and lack of registry style datasets as well as differences in resources for CPR and post-resuscitation care. Additionally, incidence and outcomes differ between in-hospital CA and out-of-hospital CA groups, with generally worse outcomes for the latter. A study of in-hospital CA from a single center in Taiwan demonstrated hospital survival of 21% with favorable neurological outcome in 16%. Another study of in-hospital pediatric CA from a single center in Pakistan demonstrated a low incidence of CA of all admissions (0.4%), likely reflecting that the majority of deaths due to CA occur prior to admission. Most CA occurred in the pediatric intensive care unit (PICU) with return of spontaneous circulation (ROSC) in 55% of patients with CA and survival to discharge in 11% of patients. In a mixed population of adults and children in a single 2,300 bed hospital in Thailand, the overall survival to discharge was 6.9%. A single study from Kenya in 2001 demonstrated that survival to discharge following in-hospital pediatric CA was 0%.

A 2009 study in multiple sites in North America observed the incidence of pediatric out-of-hospital CA to be 8 per 100,000 person years (72.7 in infants, 3.7 in children and 6.4 in adolescents). In the same study, survival for all pediatric out-of-hospital CA was 6.4% (3.3% for infants, 9.1% for children and 8.9% for adolescents). A 2010 study in Korea observed the incidence of pediatric out-of-hospital CA to be 4 per 100,000 person years (67 in infants, 3 in children and 4 in adolescents). In the same study, survival for all pediatric out-of-hospital CA was 4.9% (2.9% for infants, 4.7% for children and 7.2% for adolescents). Data from a single center in Singapore between 1997 and 2001 demonstrated that survival to discharge following pediatric out-of-hospital CA was 4.7%.

## ETIOLOGY

The majority of pediatric CA (whether in-hospital or out-of-hospital) result from respiratory failure leading to hypoxemia and bradycardia with subsequent loss of circulation and pulseless electrical activity (PEA). Typical disease states when untreated that predispose to CA include pneumonia, sepsis, diarrhea, trauma and poisonings. Primary arrhythmias are generally less common in children, but can occur postoperatively in children with congenital cardiac disease or in the setting of myocarditis and/or cardiomyopathy as well as ingestions. Ventricular fibrillation (VF) and pulseless ventricular tachycardia (VT) can result in sudden death in older children due to previously unrecognized channelopathies and metabolic disorders of fatty acid metabolism.

## PATHOPHYSIOLOGY

The pathophysiology of CA in children differs significantly from that in adults. Adults more frequently experience CA due to VF from underlying coronary artery disease and myocardial infarction. Pediatric CA usually stems from severe hypoxia or asphyxia as a result of respiratory failure and/or circulatory shock. Refractory hypoxia and/or tissue hypoperfusion favors anaerobic metabolism with resulting lactic acidosis. Both hypoxia and acidosis lead to myocardial depression, which ultimately leads to CA. In South Asia and Africa, pneumonia, diarrhea, sepsis and trauma are the leading causes of both out-of-hospital and in-hospital CA in children.

In contrast to adults, children have unique physiologic characteristics that impact their pre-arrest states, mechanisms of arrest and post-arrest outcomes. Children exhibit rapid developmental changes that affect cardiac and respiratory physiology during pre-arrest, intra-arrest and post-arrest phases. Neonates undergo transitional physiological changes from the in utero environment to an external, gaseous environment at the time of birth. Neonates and infants have much lower cardiac and respiratory reserve, and higher pulmonary vascular resistance compared to older children. Certain children have pre-existing developmental defects and other organ dysfunction, which significantly increase their risk for CA and pose additional challenges to successful CPR following CA. Additionally, due to developmental differences, neurologic assessment scales and tools that are suitable for one age group may not be accurate or valid at other age groups.

There are four well-described phases of CA: (1) pre-arrest, (2) no-flow (untreated CA), (3) low-flow (CPR), and (4) post-arrest phase. The *pre-arrest phase* includes pre-existing conditions (e.g., neurologic, cardiac, respiratory, or metabolic abnormalities), developmental status (e.g., preterm neonate, term neonate, infant, child, or adolescent), and precipitating events (e.g., respiratory failure or shock). It may represent a period of low, normal, or high blood flow. During the *no-flow or arrest phase*, there is no blood flow to vital organs, including the brain and the heart. Depending upon the duration of no-flow state, neurons suffer varying degrees of primary damage. During *low-flow or CPR phase*, external chest compressions provide approximately 20% of baseline cardiac output. The provision of high-quality CPR during this phase determines vital organ perfusion. The delivery of CPR to achieve adequate cerebral and myocardial perfusion pressures is essential for ROSC and overall survival, including neurological outcome. The *post-arrest phase* can be divided into an immediate post-arrest phase and a late post-arrest phase. In the immediate post-arrest phase, ischemia-reperfusion leads to a cascade of pathophysiologic changes in vital organs. Ischemia-reperfusion induces systemic inflammatory response with release of cytokines and chemokines that lead to multiple organ dysfunction (MOD). Similarly, a neuroinflammatory response due to ischemia-reperfusion leads to secondary neuronal injury leading to encephalopathy. In the late post-arrest phase, recovery is characterized by neurologic deficits of varying degrees depending upon the severity of encephalopathy (**Fig. 1**).

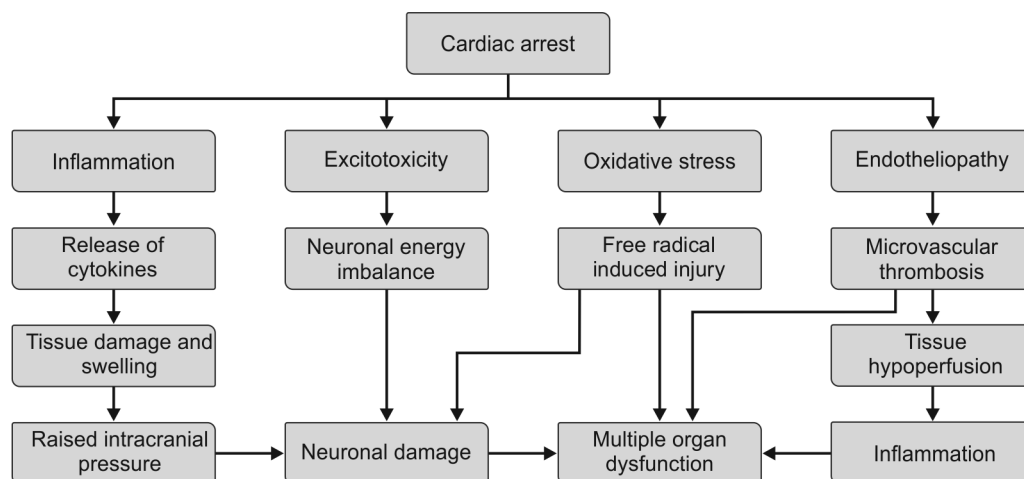

## CLINICAL FEATURES

While recognition of a child in CA is fairly straightforward due to lack of signs of life, it is very important to recognize children at risk for progression to CA so that prompt measures can be instituted to stabilize the child and prevent CA. Laypersons often mistake agonal respirations for good breathing efforts and fail to provide CPR when indicated. Changes in mental status can often be difficult to discern in a tired child that is progressively getting sicker. Fevers can mask signs of dehydration with mistakes in assessment and treatment. In general, during the pre-arrest phase, the child usually has significant derangements in vital signs and organ dysfunction with associated laboratory abnormalities.

## MANAGEMENT

The goal of CPR for CA is not only ROSC and survival, but importantly favorable neurological outcome. The key to successful CPR is early recognition of CA and prompt institution and maintenance of high-quality CPR with adjunct measures.

During the pre-arrest phase, management strategies should focus on early recognition and aggressive management of respiratory failure and shock to prevent an arrest. For example, public health education to identify warning signs of respiratory failure and dehydration can result in parents seeking help before progression to CA. The development of hospital code teams and monitoring systems in hospitals can help identify children that are progressing toward CA and help institute measures to stabilize them prior to CA. Another important but frequently overlooked aspect of pre-arrest care in children with refractory hypoxia and shock is anticipating and preparing for CA during stabilization. Lack of preparation and anticipation can result in precious seconds ticking away while efforts are made to scramble to respond to CA. For example, a child with septic shock and refractory hypotension from intravascular volume depletion and poor cardiac output is at very high risk of experiencing CA during intubation and/or line placement attempt. Preparation for such situations would include administering fluid bolus, correcting electrolyte abnormalities and intubating under controlled, titrated sedation but also importantly being ready with all medications (epinephrine, atropine, dextrose, electrolytes), equipment (backboard under the patient, step stool for chest compression provider and defibrillator) and personnel (chest compressions, administration of medications, and documentation) for managing an impending CA. Since there is a clear evidence that early institution of high-quality CPR improves

**Figure 1** Pathophysiology of cardiac arrest leading to neuronal damage and multiple organ dysfunction

outcome from CA, every effort should be made to avoid delay in recognition of CA and prompt institution of high-quality CPR. For example, refractory hypoxia and shock frequently lead to bradycardia in children which in turn leads to pulseless state and CA. Since there is clear evidence of improved outcome in children who receive CPR for bradycardia with a weak pulse compared to pulseless CA, one should commence CPR in children with bradycardia with a weak pulse immediately upon recognition.

During the no-flow or arrest phase, high-quality CPR is warranted and together with early defibrillation (when indicated) possibly the only measures definitely shown to improve outcome from CA. Providers should follow pediatric advanced life support (PALS) algorithm for CPR and focus on monitoring and delivering high-quality CPR. For high-quality chest compressions, one should follow the AHA mantra of *push hard, push fast, avoid interruptions and allow full recoil*. Every component of high-quality CPR has strong physiologic basis supported by good quality evidence through animal and human research. Through the studies using CPR quality-sensing devices, it is well established that quality of in-hospital CPR is often suboptimal and can be associated with worse patient outcomes. In a study on adult in-hospital CA, 23% of chest compressions were found to be associated with incorrect rates and 36% of the chest compressions were too shallow. In a porcine model of asphyxia CA, deeper chest compressions resulted in improved hemodynamic and short-term survival outcomes. Use of step stool by chest compression providers and a backboard under the patient have been shown to improve the quality of chest compressions. Adequate coronary perfusion pressure during CPR is essential for myocardial preservation and return of circulation. Coronary perfusion pressure depends on diastolic blood pressure and right atrial pressure. The spontaneously beating heart receives the majority of its perfusion during diastole with linear correlation between coronary artery blood flow and aortic diastolic pressure. During chest compressions, aortic pressure rises concurrently with right atrial pressure. During chest decompression, the right atrial pressure falls faster and lower than the aortic pressure, generating a pressure gradient that perfuses the heart. Thus, coronary perfusion occurs during diastole or the *release* of chest compression. In a porcine model of asphyxial CA, survival was improved when CPR was targeted to a coronary perfusion pressure of more than 20 mm Hg (hemodynamic goal-directed CPR). Similarly, end-tidal carbon dioxide level (a surrogate for cardiac output) more than 10–15 mm Hg during CPR is associated with improved survival outcomes. Clinical and laboratory studies have shown that the delivered ventilation rate during CPR frequently exceeds AHA guidelines and is associated with poor cardiac output during CPR. Hyperventilation leads to increased intrathoracic pressure, which in turn impedes venous return to the heart and thereby decreases cardiac output. It is, therefore, very important to ventilate at the specified rate especially as the majority of pediatric CA result from respiratory failure. Appropriate identification and management of CA rhythms by health-care providers have also been shown to be deficient in actual practice. For VF and pulseless VT-CA, prompt defibrillation and high-quality CPR are recommended. As the mortality rate increases by 7–10% per minute of delay to defibrillation, such delays in treatment must be avoided. Patient factors (like location at the time of arrest, witnessed/unwitnessed, comorbidities, age, sex, and race) and provider factors (like CPR quality, teamwork, identification and reversal of cause of arrest) determine outcomes from CA. The importance of diagnosing and treating the underlying cause of arrest is fundamental to the management of all CA. PEA is often caused by reversible conditions and can be treated successfully, if

those conditions are identified and corrected. According to AHA guidelines for management of CA, the provider should recall the Hs and Ts to identify factors that may have resulted in the arrest or may be complicating resuscitative efforts.

For all practical purposes, the depth of chest compressions should be at least one-half the anterior-posterior diameter of the chest and delivered at least at a rate of 100 compressions per minute in children. Providers should allow full recoil during chest compressions and avoid learning to improve passive return of blood into the right heart. It is highly recommended to switch the chest compression provider every 2 minutes due to development of provider fatigue and inability to maintain high-quality CPR. One should remember to use a backboard under the patient and a step stool for chest compression provider to improve chest compression quality, monitor and use hemodynamic parameters like arterial blood pressure (whenever an arterial line is in place) and end-tidal carbon dioxide levels (through capnography) to improve the quality of CPR.

Lack of leadership and poor teamwork can result in poor clinical outcomes from CPR, even if high-quality CPR is delivered. CPR is associated with chaos and stress among team members, especially, if there is a lack of clear leadership, communication, teamwork and increased conflicts among team members. Previous studies have established the crucial role of leadership in managing emergency situations—clear leadership is associated with improved cooperation within team, task performance, and transfer of information with decreased team conflicts. A code leader is expected to perform multiple roles while leading a code—role assignment, data analysis, problem-solving, monitor multiple physiologic parameters, monitor parameters of quality of CPR, ensure delivery of high-quality CPR through feedback to the team members and ensure good team communication while orchestrating the AHA algorithm of CPR and working toward identifying and treating reversible causes of CA.

During the post-arrest phase, the patient should be managed in a dedicated PICU with close monitoring of parameters of vital organ perfusion, such as heart rate, respiratory rate, urine output, lactate levels, systemic mixed venous saturation and neurological status, through frequent and regular clinical examination as well as electroencephalography (EEG), when available. Providers should aim for normoxemia and normocarbida through optimum titration of ventilator settings. It is important to monitor and support metabolic parameters to avoid hyponatremia and maintain normoglycemia. Progressively worsening hypoxic-ischemic encephalopathy due to secondary neuronal injury and post-arrest myocardial dysfunction are the major causes of death after initial recovery from CA. Neuroprotective strategies, such as induced mild therapeutic hypothermia and aggressive management of seizures, should be considered in comatose survivors of CA to improve outcomes. Goal-directed hemodynamic support through titrated infusions of inotropes is important to support post-arrest myocardial dysfunction.

### Special Considerations

CPR and post-resuscitation care differ between different age groups and among patients with special health-care needs. For distinct differences in CPR between patients of different ages and in special situations (congenital heart disease, trauma, drowning, toxic ingestions), readers are encouraged to refer to specific PALS and Neonatal Resuscitation Program (NRP) guidelines. In children with congenital heart disease who have undergone palliative or corrective cardiac surgery, the open-chest wound poses unique challenges with effective external cardiac compressions. In such circumstances, inexperienced providers should begin external chest compressions near the edges of the sternal wound or from

the sides until open cardiac massage can be started by a skilled provider such as the surgeon. In patients with severe pulmonary hypertensive crisis leading to CA, pulmonary vasodilators such as inhaled nitric oxide should be continued during CPR. Since the current literature supports use of therapeutic hypothermia for neonatal hypoxic ischemic encephalopathy and comatose adult victims of CA, therapeutic hypothermia should be initiated soon after ROSC in neonates and adolescents. While the results of the therapeutic hypothermia after pediatric CA trial are awaited, one could consider use of induced, mild hypothermia (32–34°C) in comatose children after CA arrest for 24–48 hours followed by slow rewarming over 24 hours.

## OUTCOMES/PROGNOSTIC FACTORS

Though recent studies have shown an overall increase in the number of pediatric CA survivors without severe neurological disability over time, a significant number of children continue to exhibit mild or moderate neurologic disability after CA. The prognosis is invariably poor in comatose patients with absent pupillary or corneal reflexes, or absent or extensor motor responses 3 days after CA. Patients with myoclonic status epilepticus within the first day of arrest have a poor prognosis. Prognosis cannot be based on circumstances surrounding CPR like duration of anoxia or CPR, cause of the arrest and type of cardiac arrhythmia. Bilateral absent cortical somatosensory evoked potential within 1–3 days following arrest predict poor outcome. Burst suppression or generalized epileptiform discharges on EEG predict poor outcomes, but not with high accuracy. High-serum neuron-specific enolase levels at days 1–3 after arrest accurately predict poor outcome, but there are inadequate data to support or refute the prognostic value of other serum and cerebrospinal fluid biomarkers, neuroimaging and intracranial pressure monitoring.

## PREVENTION

Almost every CA in children is preventable. Since the majority of CA in children result from refractory hypoxia and/or circulatory shock, early recognition and aggressive management of respiratory and circulatory failure could potentially prevent CA. Preventive measures need to be applied not only at a micro level (initial and booster training on PALS and NRP, hospital code teams, monitoring systems), but also at a macro level (policymaking, community training, World Health Organization guidelines, financial support for preventive health).

## IN A NUTSHELL

1. The International Liaison Committee on Resuscitation leads international efforts to develop and revise guidelines for CPR every 5 years.
2. Majority of pediatric CA result from respiratory failure leading to hypoxemia and bradycardia with loss of circulation and PEA.
3. Pathophysiology of CA in children differs significantly from adults due to differences in growth and development.
4. The four phases of CA include pre-arrest, no-flow, low-flow and post-CA phases.
5. Development of rapid response teams can identify children at risk for progression to CA and stabilize them.
6. Early recognition of CA and prompt institution and maintenance of high-quality CPR is essential for favorable outcomes.
7. Post-arrest management should be provided in a dedicated PICU.

## Chapter 7.3

### Basic Life Support (BLS)

Shalu Gupta

The term basic life support (BLS) is used to describe maintenance of a clear airway and support of breathing and the circulation in cases of cardiac arrest, without the use of equipment other than a simple airway devices or resuscitating bags. Cardiopulmonary resuscitation (CPR) is the combination of chest compression and rescue breathing, and forms the basis of modern BLS. Rapid and effective bystander CPR is associated with successful return of spontaneous circulation (ROSC) and neurologically intact survival in children.

The chances of survival after cardiac arrest are increased when the event is witnessed and when a bystander institutes CPR prior to the arrival of the emergency services. The major causes of death in infants and children are respiratory failure, sepsis, neurological diseases, injuries and sudden infant death syndrome. The best chance of a successful outcome for the patient is achieved if chest compressions are started as soon as cardiac arrest is diagnosed. The key changes in the current American Heart Association BLS 2010 guidelines are highlighted (**Table 1**). Infants' BLS guidelines apply to infants less than 1 year of age, child guidelines apply for children from 1 year till puberty, and adults are beyond puberty. Puberty is defined as breast development in females and presence of axillary hairs in males.

**Table 1** Key changes in AHA CPR guidelines 2010

S. No.	Recommendations 2010
1.	Change of BLS sequence from A-B-C to C-A-B
2.	Emphasis on high quality CPR
3.	Removal of <i>look, listen, feel</i> from the initial assessment
4.	Use of cricoid pressure is not recommended
5.	For infants a manual defibrillator is preferred. If a manual defibrillator is not available, an AED with pediatric dose attenuator may be used. If neither is available an AED without a dose attenuator may be used
6.	Recovery position is recommended
7.	De-emphasis on pulse check
8.	Emphasis on team resuscitation concept

Abbreviations: AHA, American Heart Association; CPR, cardiopulmonary resuscitation; BLS, basic life support; AED, automated external defibrillator; A-B-C, airway-breathing-compression; C-A-B, compression-airway-breathing.

### THE CHAIN OF SURVIVAL

Most of the arrests in children and infants are secondary to respiratory failure and shock. Therefore, early identification of the illness and early institution of the treatment reduce the likelihood of developing pediatric arrest. A preventive link is added so as to identify at risk children early. The five key components of pediatric chain of survival are listed in **Box 1**.

#### BOX 1 Key components of pediatric chain of survival

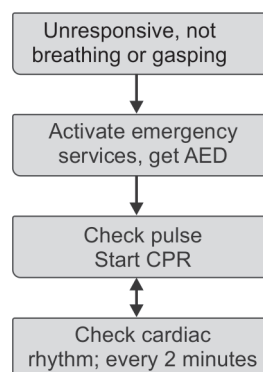

- Prevention of arrest
- Early institution of high quality cardiopulmonary resuscitation
- Rapid activation of the emergency response system
- Effective advanced life support (rapid stabilization, transport, and rehabilitation)
- Integrated postcardiac arrest care.

### CAB or ABC?

As per the revised 2010 guidelines, CAB (chest compression, airway, breathing/ventilation) is recommended (**Flow chart 1**). This despite the fact that most of the cardiac arrest in pediatric age group is asphyxial and therefore, ventilations are extremely important in resuscitating such kids. However, there is not enough evidence to support whether the sequence starting with ventilations [ABC (airway, breathing, compression)] is any different from sequence starting with compressions (CAB). The steps of BLS for a health-care provider are shown in **Table 2**. The C-A-B sequence was preferred because of the following reasons:

- In adults the major cause of cardiac arrest is ventricular fibrillation (VF); here chest compressions, if started early carry a better outcome with minimal interruptions.
- Starting chest compression is easy and quick, as compared to positioning of head, opening the airways and giving rescue breaths. This would improve the likelihood of receiving a bystander CPR in a pediatric arrest victim.
- Starting CPR with compression first with a compression ventilation ratio of 30:2, delays ventilation by only 18 sec for a lone rescuer. This interval further decreases when there are two rescuers.
- It offers harmonization of guidelines across age groups.

**Flow chart 1** Simplified steps in basic life support

Abbreviations: AED, automated external defibrillator; CPR, cardiopulmonary resuscitation.

**Table 2** BLS sequence for healthcare providers

Steps	Action to be taken
Step 1	Assess that the scene is safe
Step 2	Check the responsiveness and breathing. If there is no response, no breathing or only gasping, shout for help
Step 3	If you are alone, for sudden witnessed arrest activate the emergency response system, get an AED and return
Step 4	Check the central pulse (within 10 sec) either carotid, brachial or femoral artery
Step 5	If there is no pulse or despite adequate oxygenation and ventilation the heart rate is <60/min with signs of poor peripheral perfusion, start chest compressions
Step 6	Give 2 rescue breaths
Step 7	After about 2 min, or 5 cycles, if not done, activate the emergency response system and get an AED/defibrillator
Step 8	Apply AED pads and check for the cardiac rhythm
Step 9	If the rhythm is shockable, give shock followed immediately with CPR

Abbreviations: AED, automated external defibrillator; CPR, cardiopulmonary resuscitation.

## Assessment of the Scene

Always make sure that the place where CPR is to be carried is safe both for the rescuer and the victim. Check for the responsiveness and breathing of the victim. If a victim is not responsive and not breathing or not breathing normally (gasping), activate the emergency response system and start CPR.

**Agonal breathing** Agonal breathing or gasps is not a normal breathing. Particular care should be taken to recognize agonal breathing (irregular, often noisy, gasps) as a sign of cardiac arrest and not a sign of life. Gasps may appear forceful or they may be weak, and there may be some time gap in-between gasps. In an unresponsive victim, it is a sign of cardiac arrest.

**Pulse check** Take at least 5 sec and *not more than 10 sec* to feel for a central pulse. If within 10 sec you are not able to feel or are not sure of a pulse, start CPR. Feel for brachial pulse in infants and carotid or femoral pulse in children. Although an absent central pulse in an unconscious patient is a sure sign of cardiac arrest, it has been shown that the accuracy of such a pulse check can be very poor. Unless the rescuer is trained, experienced, and confident in feeling for the carotid pulse, a diagnosis of cardiac arrest should be assumed, if the patient is unresponsive and not breathing normally.

**Inadequate breathing** If the victim has a palpable pulse greater than or equal to 60 beats per minute (bpm), but the breathing is inadequate, give rescue breaths at a rate of 12–20 breaths per minute (1 breath every 3–5 sec) till good spontaneous breathing resumes. Check pulse every 2 min.

*If the victim has a palpable pulse rate less than 60 bpm and signs of poor peripheral perfusion (cyanosis, mottling, pallor), despite providing adequate oxygenation and ventilation, start chest compression.*

**Cricoid pressure** The use of cricoid pressure has not been recommended because it may hamper ventilation and delay the placement of an advanced airway in the victim. Even if the cricoid pressure is applied, some degree of aspiration can still occur.

## Circulatory Support

The emphasis is on high quality chest compressions, so as to generate blood flow to the vital organs and to achieve ROSC. The components of high quality CPR are listed in **Box 2**.

### BOX 2 Components of high quality cardiopulmonary resuscitation

- Chest compression of appropriate rate and depth. *Push fast* at a rate of at least 100 compressions per minute. *Push hard* with sufficient force to compress at least one-third of the anterior-posterior depth of the infant's chest, or approximately 1½ inches (4 cm), and 2 inches (5 cm) in children
- Allow complete chest recoil after each chest compression to allow the heart to refill with blood. Incomplete recoil is harmful as it decreases the blood flow created by chest compressions
- Minimize interruptions of compressions
- Avoid excessive ventilations.

The compressions should preferably be given on a hard surface. The correct place to compress the chest is in the center of the lower half of the sternum. Do not compress over the xiphoid or the ribs. Use the inter-nipple line as a landmark (**Fig. 1**). Chest compression and chest relaxation or recoil time should be approximately equal. In infants, a two finger chest compression technique or a two thumb chest encircling technique can be used. The two thumb chest encircling technique (**Fig. 2**) produces better blood flow, more consistent depth of chest compression, and generates higher blood pressure, than the two finger technique (**Fig. 3**). In adults and children, you can use one or two handheel technique. Place the heel of your hand on the center of the victim's bare chest on the lower half of sternum. The rescuer's arms should be kept straight with the elbows locked.

The compression ventilation ratio for single rescuer is 30:2, i.e., after 30 compressions, open the airways and give 2 breaths. For two rescuers, the ratio is 15:2. In adults the ratio is 30:2 irrespective of the number of rescuers. If an advanced airway is in place, compression and ventilation cycles are not required. Instead, the

**Figure 1** The position of the hands during chest compression in a child

**Figure 2** Two thumb chest encircling hand technique in infants

**Figure 3** Two finger chest compression technique in infants

chest compression should be given at least 100 per minute without pausing for ventilation. The breaths should be given at a rate of 8–10 breaths per minute (breath every 6–8 sec).

### Ventilatory Support

To open the airway, the patient's head should be tilted backwards (without hyperextension of the neck) and the jaw lifted to pull the tongue forward off the posterior pharyngeal wall (head-tilt chin-lift maneuver) (**Fig. 4**). If cervical spine injury is suspected a jaw thrust maneuver without head tilt should be used. If the rescuer is not able to provide ventilation, the lay rescuer should continue with chest compressions only.

To give breaths to an infant, mouth-to-mouth and nose, can be used. In children, mouth-to-mouth technique can be used. To give mouth-to-mouth ventilation, the patient's nose should be pinched closed. The rescuer should then take a breath, make a firm seal with his or her lips around the patient's mouth, and breathe out, watching as the victim's chest rises. This should take about a second, and it is important to avoid overinflation as this will allow air to enter the esophagus and stomach. Subsequent gastric distension causes not only vomiting but also passive regurgitation into the lungs, which often goes undetected. The expired air is then allowed out passively.

**Figure 4** Head-tilt chin-lift maneuver for opening the airways

Because of the potential risk of transmission of infection, some form of barrier device, preferably a ventilation mask (for mouth-to-mask ventilation) or a filter device placed over the mouth and nose can be used. Bag and mask devices can also be used by a health-care worker for giving positive pressure ventilation. The bag and mask ventilation requires competence and expertise and *is therefore not recommended by a lone rescuer during CPR*. Always select the appropriate size mask for the victim.

The quality of chest compressions deteriorate with time as the rescuer gets fatigued. Therefore the rescuer should switch roles, and rotate his position every 2 min or 5 cycles.

### Defibrillation

The two shockable rhythms are VF and pulseless ventricular tachycardia (VT). The interval from collapse to defibrillation is one of the most important factors of survival from sudden cardiac arrest following VF or pulseless VT. Children who suddenly collapse are more likely to have VF or pulseless VT and therefore require immediate defibrillation and CPR. Automated external defibrillators (AEDs) are computerized devices which can identify shockable and non-shockable cardiac rhythms, and can then deliver shock. For infants a manual defibrillator is preferred,

however if it is not available, then a pediatric dose attenuator can be used for delivering shock. If neither is available, an AED without a dose attenuator can be used. An AED with pediatric dose attenuator is also preferred for children less than 8 years of age. Immediately after delivering shock, start CPR. The AED will prompt the rescuer to reanalyze the rhythm after every 2 min.

The AED may not function properly in certain conditions. If the victim has a lot of chest hair, the AED pads will not stick properly. The AED will also not be able to analyze the cardiac rhythm properly if the victim has an implanted pacemaker, or has a transdermal medication patch, and if the victim's chest is covered with water. Removal of chest hair, medication patch and water is warranted before application of the pads. Avoid placing AED pads directly over the pacemaker.

### Basic Life Support Sequence for Lay Rescuers

The BLS steps to be performed in child or infant who is found unresponsive and not breathing or gasping are shown in **Table 3**. It should be noted that the emphasis is again on high quality chest compression. Also, if the lay rescuer is not trained or is not able to provide ventilation, he should continue with chest compression only. *There is no need to check for pulse (Table 3)*.

**Table 3** Steps of basic life support for a lay rescuer

Steps	Action to be taken
Step 1	Ensure that the area is safe for you and the victim
Step 2	Look for responsiveness and breathing. If child/infant is not responsive, and not breathing or gasping, shout for help immediately if alone. Otherwise send the second rescuer to activate the local emergency response system
Step 3	If the victim is breathing with no injury, turn the victim onto left side ( <i>recovery position</i> )
Step 4	If the victim is not responsive, and not breathing or gasping, start CPR
Step 5	Open airways and provide ventilation
Step 6	Coordinate chest compression and ventilation
Step 7	Activate the emergency response system

Abbreviation: CPR, cardiopulmonary resuscitation.

### Choking

Foreign body airway obstruction is an emergency. The common causes of choking are liquids in infants and food items (e.g., nuts, round candies, and grapes), balloons and small objects in children. Early recognition and prompt removal of the airway obstruction are the keys to success. Airway foreign bodies can cause symptoms ranging from mild-to-severe airway compromise. Signs of choking included sudden onset of coughing with or without respiratory distress, gagging, stridor, or wheezing. In mild airway obstruction, the victim has good air exchange, and coughs forcefully with wheeze. However, in severe airway obstruction, the victim will have poor or no air exchange, weak or ineffective cough, weak or no voice, respiratory difficulty and cyanosis. The victim will often be seen clutching his neck with his hands (*universal choking sign*).

If the airway obstruction is mild, do not interfere and allow the victim to have spontaneous coughing and breathing effort. Allow him to expel the foreign body by his own attempt, and monitor for any deterioration. If there is severe airway obstruction, perform a subdiaphragmatic abdominal thrust (*Heimlich maneuver*) until the foreign body is expelled or the victim becomes unconscious. If the child becomes unconscious, activate the emergency response system and start CPR with one exception. Every time you open the

airway to ventilate, look for the foreign body. If you are able to see a foreign body, remove it with your fingers gently. *Do not do blind finger sweep.*

In an infant with severe airway obstruction, hold the infant facedown with the head slightly lower than the chest, deliver up to 5 back slaps forcefully between the infants shoulders blade, using the heel of your hand, then deliver up to 5 downward chest thrusts in the middle of the chest. Repeat this sequence of 5 back slaps and 5 chest thrusts, until the foreign body is expelled or the victim becomes unconscious. If the infant becomes unconscious, activate the emergency response system and start CPR with one exception.

Highlights of the 2010 American Heart Association Guidelines for Cardiopulmonary Resuscitation and Emergency Cardiovascular Care. Dallas, TX: American Heart Association; 2010.

### IN A NUTSHELL

1. Agonal breathing or gasps is not a normal breathing. It is a sign of cardiac arrest and not a sign of life.
2. Do not take more than 10 sec to feel for a pulse.
3. Provide high quality cardiopulmonary resuscitation.
4. Use head-tilt, chin-lift maneuver for opening the airways after ruling out cervical spine injury.
5. Give two slow breaths.
6. The compression ventilation ratio for single rescuer is 30:2, and for two rescuers the ratio is 15:2.
7. Use automated external defibrillator as soon as possible for shockable rhythms. For infants, a manual defibrillator is preferred.
8. Recognize early signs of choking (universal choking sign).

## Chapter 7.4

# Pediatric Advanced Life Support (PALS)

Banani Poddar

The vast majority of children who deteriorate to cardiac arrest do so as a result of respiratory failure or shock. Cardiac arrhythmias or primary cardiac conditions leading to so called *sudden cardiac arrest* is rare in children and constitutes only 10–15% of all cardiac arrest. While it is feasible to recognize and treat children with respiratory and cardiac illnesses with good outcomes, the outcome of cardiac arrest in children (in-hospital and especially out of hospital) is generally dismal. Survival is around 27% for in-hospital cardiac arrests and 6% for out-of-hospital cardiac arrests. Hence, it is of utmost importance to prevent cardiac arrest.

In a patient who has progressed to cardiac arrest, the important determinant of a good outcome is the early institution of basic life support. Often, pediatric cardiac arrest takes place at home or at school; hence, the importance of basic life support, which is known as *bystander cardiopulmonary resuscitation (CPR)*, cannot be overstated. Advanced life support is successful only when good quality BLS has been instituted in a timely fashion.

## Recapitulation of Rapid Cardiopulmonary Assessment of a Sick Child

The systematic and stepwise assessment of the seriously ill or injured child has been described earlier and is shown in **Table 1**. To recapitulate, this consists of:

**Initial impression** A rapid visual and auditory assessment and includes a quick overview of consciousness, breathing and color. This quick *from the door* assessment helps in deciding whether the patient has a life-threatening condition, in which case immediate therapy is instituted.

**Primary assessment** This is a rapid hands-on approach of airway, breathing, circulation, disability and exposure (ABCDE). Each aspect is evaluated systematically and helps in assessing the type and severity of physiologic derangements.

**Secondary assessment** A focused history and focused systemic examination further adds to the primary assessment.

**Tertiary assessment** This consists of the important laboratory tests and radiology which help in assessing the child's physiology.

If at any time during above evaluation, a life-threatening problem is identified, immediate therapy is instituted. Further, the cycle of evaluate, identify and intervene is used sequentially so as to be able to identify problems, intervene appropriately and re-evaluate for any change in the patient's status. During the resuscitation process, repeated reassessments are required to assess the effects of therapy and further improvement or deterioration.

With the above assessment, the child could be identified to be one of the following:

- Stable
- In respiratory failure and/or shock
- In cardiopulmonary failure.

The management of respiratory failure and shock are dealt with in other chapters. The child in cardiopulmonary failure needs immediate attention as the child may deteriorate to cardiac arrest in a few minutes. Call for help immediately and proceed to manage the child according to the cardiac arrest algorithm. Check for a

pulse, if that is absent, start CPR with chest compressions first. If a pulse is present, check for breathing. If the patient is not breathing, start rescue breathing. If in spite of adequate ventilation and oxygenation, the child's heart rate is less than 60/min, start chest compressions. If the patient's breathing is adequate, proceed for a complete evaluation.

## BRADYARRHYTHMIAS

### Definition

A heart rate which is less than normal for the age and level of activity of the child is referred to as bradycardia. Since the heart rate of a child is different in different age groups (*refer to* chapter 7.1, Table 2), a fixed heart rate cannot be defined; however, a heart rate less than 60/min is ominous. When bradycardia is associated with an abnormal rhythm, a bradyarrhythmia is said to exist.

### Causes

Bradycardia can be either due to cardiac conditions (primary) or noncardiac conditions (secondary). While the former is due to a disease process of the cardiac conduction system due to congenital or acquired heart conditions, the latter is due to other conditions. Secondary bradycardia is much more common in critically ill children and is seen with hypoxemia, hypothermia, metabolic acidosis, hypotension, raised intracranial pressure (ICP) and as a result of drugs. When associated with signs of shock and/or respiratory distress or failure, this is referred to as symptomatic bradycardia. Hypoxemia is the most common cause of bradycardia in children.

### Signs and Symptoms

It is usually seen terminally before a cardiac arrest. Hence, the child is usually unresponsive and has gasping respiration. Cardiac output is a product of stroke volume and heart rate. The child has a limited capacity to increase the stroke volume and hence a fall in heart rate is associated with a fall in cardiac output. The patient develops features of hypotensive shock with altered sensorium and finally cardiopulmonary failure and cardiac arrest.

### ECG Changes

Electrocardiogram (ECG) changes seen with bradycardia include: (1) Sinus bradycardia; and (2) atrioventricular block (AV block). **Figures 1A to D** show various bradycardia rhythms. The management of AV block requires expert opinion and further details are not elaborated here. However, symptomatic bradycardia is managed irrespective of the ECG rhythm.

### Management

The priorities of management include: (a) adequate oxygenation and ventilation; (b) good quality CPR, if there is no response to the above; and (c) attachment to a monitor to identify the rhythm. Drugs have a limited role. The steps in the management of symptomatic bradycardia are summarized in **Flow chart 1**. Open the airway and ensure a patent airway. In case of a patient with an advanced airway, tube blockage by secretions could cause bradycardia; clear the airway by suctioning. Assist breathing, if necessary. Administer 100% oxygen. Attach the patient to a monitor to ascertain the rhythm. Establish intravenous (IV)/intraosseous (IO) access. Following the above actions, reassess cardiopulmonary status.

- If heart rate continues to be less than 60/min with poor perfusion, start chest compressions
- If bradycardia persists, administer the following drugs:
  - Epinephrine IV/IO or endotracheal (ET); repeat every 3–5 min. Adrenaline or epinephrine is available as 1:1000

**Table 1** Recapitulation of pediatric assessment

Initial impression					
Consciousness		Breathing		Color	
Primary assessment					
Airway					
Clear		Maintainable		Not maintainable	
Breathing assessment					
Respiratory rate and pattern		Respiratory effort	Chest expansion and air movement	Abnormal lung/airway sounds	Pulse oximetry
Normal	Normal	Normal	Gurgling	Normal oxygen saturation (> 94%) Hypoxemia	
Irregular	Increased	Decreased	Stridor		
Fast	Nasal flaring	Unequal	Snoring		
Slow	Retractions	Prolonged expiration	Barking cough		
Absent (apnea)	Head bobbing		Hoarseness

Abbreviation: AVPU, alert, voice, pain, unresponsive.

solution; it is diluted 10 times to a concentration of 1:10000. The dose is 0.1 mL/kg of 1:10000 solution IV/IO and 0.1 mL/kg of 1:1000 solution for ET administration.

- **Atropine:** Atropine is indicated only when increased vagal tone is suspected or in primary AV block; can repeat after 5 min. The dose is 0.02 mg/kg (a minimum dose of 0.1 mg must be used).
- In case of persistent bradycardia, consider pacing.
- Look for and correct the correctable causes of bradycardia; e.g., metabolic acidosis, hypothermia, raised ICP, drug intoxication

- If there is no cardiopulmonary compromise, continue to support airway, breathing, and circulation (ABC) with oxygen. Evaluate the rhythm and consult a pediatric cardiologist.

At any time, if the child develops pulseless arrest, manage according to the cardiac arrest algorithm.

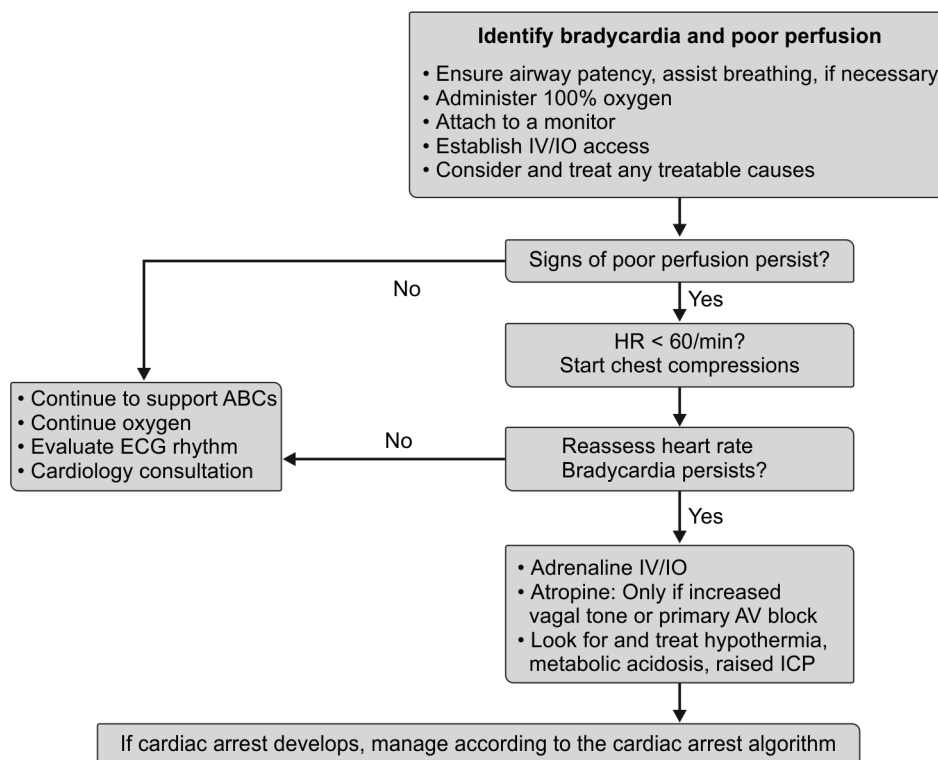

## TACHYARRHYTHMIAS

Tachycardia is a heart rate greater than normal for the age of the child. Tachycardia is common and often, a nonspecific response to any stress, anxiety or illness. When associated with an abnormal rhythm, it is referred to as tachyarrhythmia.

**Figures 1A to D** Bradycardia: (A) Sinus bradycardia; (B) First degree AV block; (C) 2:1 AV block; and (D) Complete AV block

**Flow chart 1** Management of pediatric bradycardia with cardiopulmonary compromise

Abbreviation: ICP, intracranial pressure.

## Causes

*Sinus tachycardia* is seen as a result of any underlying condition such as fever, dehydration, pain, anxiety or any other stress. However, in a critically ill child, tachycardia is a marker of an underlying problem and a search for the cause is warranted.

*Supraventricular tachycardia (SVT)* An abnormal tachyarrhythmia where the origin is in the atria or AV node. AV reentrant tachycardia, atrial ectopic tachycardia and AV junctional tachycardia are the different types of supraventricular tachycardia. **Table 2** highlights the key differences between sinus tachycardia and SVT.

*Ventricular tachycardia (VT)* Here, the abnormal tachyarrhythmia originates in the ventricles.

## Diagnosis and Management

A rise in the heart rate initially causes an increase in the cardiac output. However, beyond a certain stage, the time for filling of the ventricles decreases and the cardiac output falls. Children, especially infants, with SVT can remain asymptomatic for a variable period of time. After a certain time, the compensatory mechanisms fail and hemodynamic compromise ensues. Older children, on the other hand, become conscious of the fast heart rate and complain of palpitations. Infants can have nonspecific complaints of excessive fussiness and refusal of feeds. In children with pre-existing heart diseases, SVT can cause significant hemodynamic compromise. VT, on the other hand, compromises ventricular filling and contraction; hence hemodynamic compromise is seen early. Moreover, it is an unstable rhythm and often changes to ventricular fibrillation (VF) or pulseless VT. Thus, a child with VT should be managed urgently. The two important points to note for the emergent management of tachycardia are:

1. Presence of hemodynamic compromise (signs of poor perfusion including weak pulses, prolonged capillary refill,

signs of shock, hypotension, respiratory distress and altered sensorium)

2. Duration of the QRS complex on the ECG.

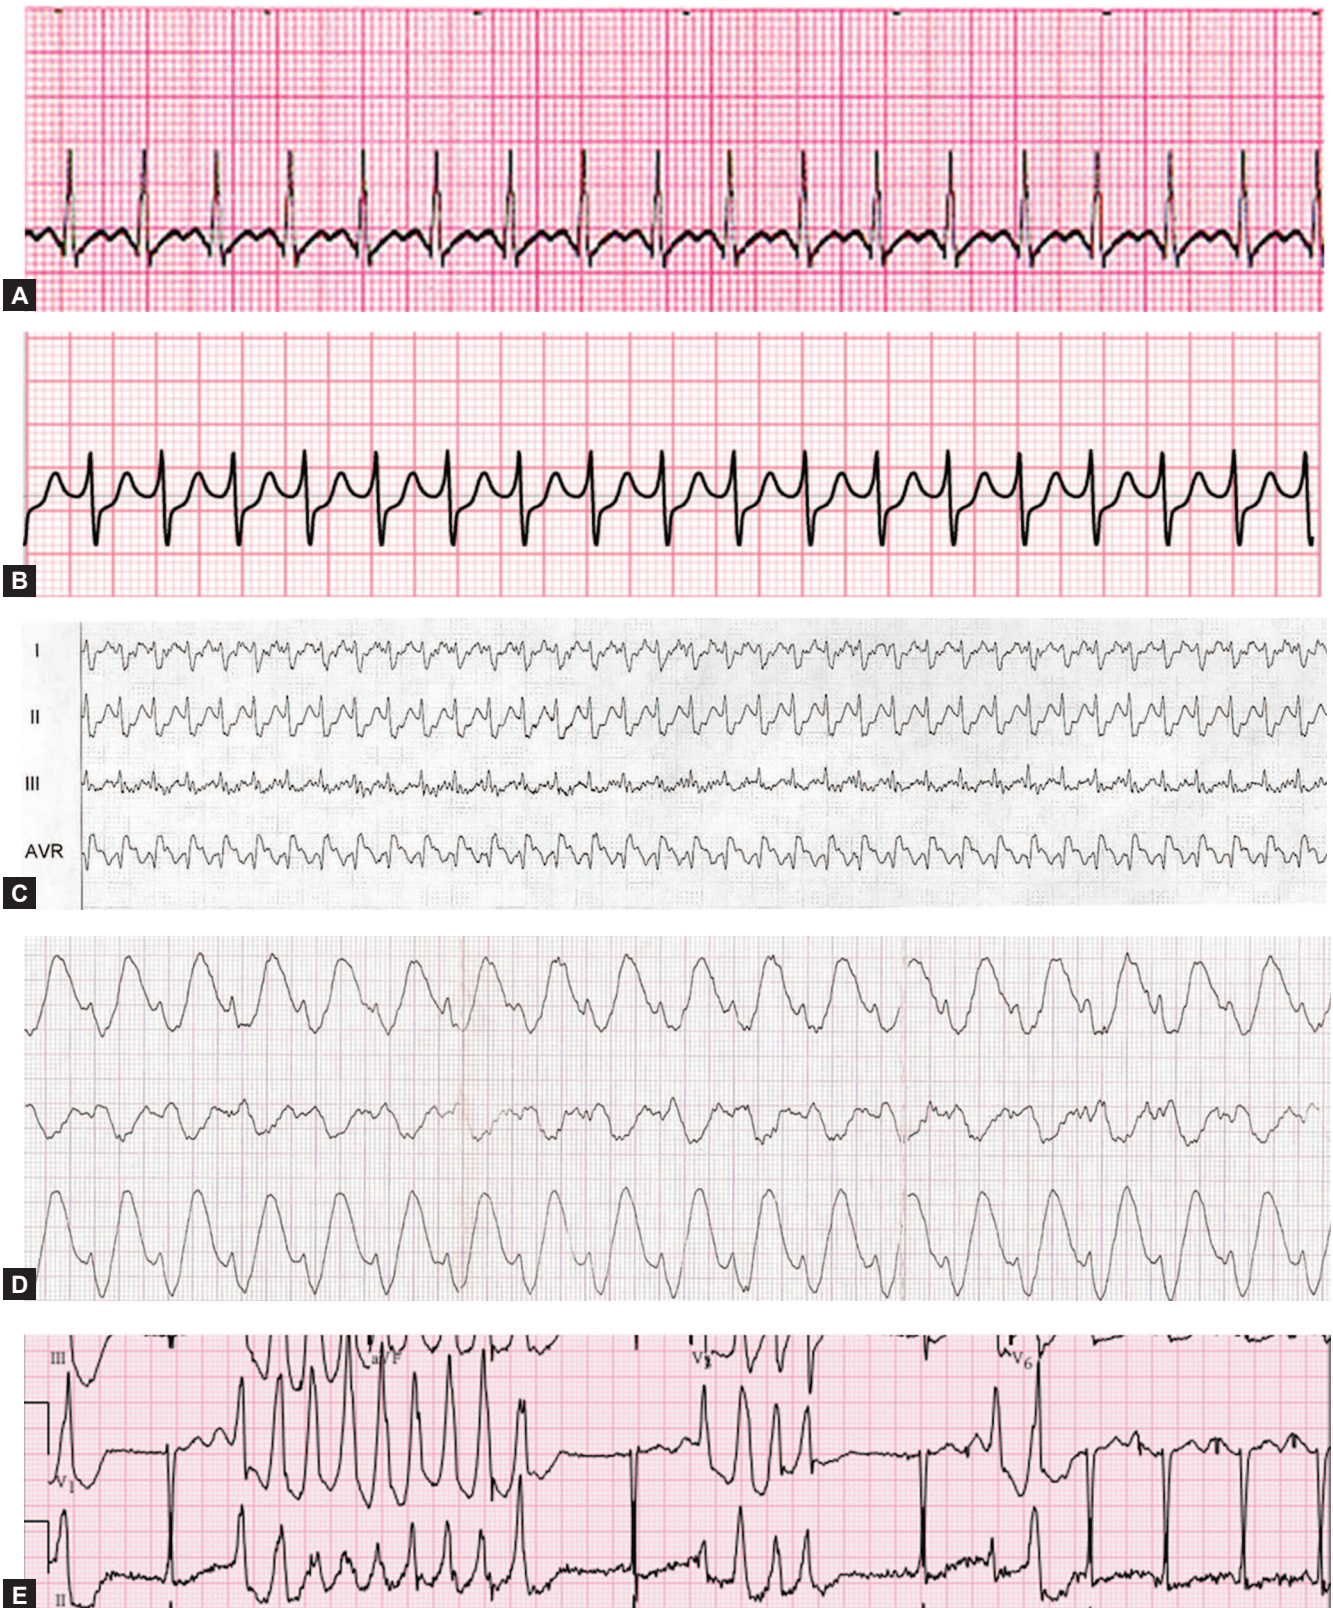

Narrow complex tachycardia (QRS duration < 0.09 sec) is a sinus tachycardia or SVT. Wide complex tachycardia (QRS duration ≥ 0.09 sec) are ventricular tachycardia (VT) or rarely, SVT with aberrant conduction. **Figures 2A to E** show various tachycardia rhythms. In the presence of signs of poor perfusion, the rhythm is said to be unstable and this should be treated urgently.

*Sinus tachycardia* The heart rate is increased in response to some condition such as fever, dehydration, etc. (**Table 2**). A history compatible with a reason for tachycardia, presence of P waves on ECG and change in heart rate with activity are the cardinal features to differentiate sinus tachycardia from SVT. A search for the cause of tachycardia and treatment of the underlying cause are all that is required.

*Supraventricular tachycardia* The management depends on the presence of hemodynamic compromise. In a hemodynamically stable child (stable SVT), there is no urgency of management and the patient can be evaluated thoroughly, while monitoring the patient for signs of shock. Steps of management of SVT are outlined in **Box 1**.

*Ventricular tachycardia* The presence or absence of signs of poor perfusion would dictate the steps in management. The initial steps in the management (ABC, oxygen, ECG monitoring, vascular access) remain the same. Further management differs in the two situations: *In a patient with adequate perfusion*, pharmacologic conversion of the rhythm with amiodarone or procainamide is preferred. Lidocaine may also be used, if these drugs are not available. Adenosine may be administered, if the child is stable and there is any doubt about the rhythm. Adenosine would not affect the rhythm in a VT but an SVT would revert. *In a patient with poor perfusion*, synchronized cardioversion is preferred.

**Figures 2A to E** Tachycardia: (A) Sinus tachycardia; (B) Supraventricular tachycardia; (C) SVT with aberrant conduction; (D) Ventricular tachycardia; and (E) Torsades de pointes

**Table 2** Differentiation between sinus tachycardia and SVT

Factors	Sinus tachycardia	Supraventricular tachycardia
History	Gradual or insidious onset Reason for tachycardia obvious (fever, dehydration, hemorrhage, pain)	Abrupt onset Nonspecific history, especially in infants; symptoms s/o CHF +/-
Heart rate	Infant: Usually $\leq 220$ /min Child: Usually $\leq 180$ /min	Infant: Usually $> 220$ /min Child: Usually $> 180$ /min
ECG	P waves: Normally present (upright in leads I/aVF) R-R interval: Variable with activity	P waves: Absent/inverted/abnormal (inverted in leads II/III/aVF) R-R interval: No variation
Chest X-ray	Normal, unless pneumonia is the cause of ST	Cardiomegaly, pulmonary edema may be present

**BOX 1 Steps of management in a supraventricular tachycardia**

- In stable SVT, the steps of management are:
  - Support ABCs and oxygenation as required
  - Attach to a monitor
  - Obtain a 12 lead ECG and identify the rhythm
  - Identify and treat reversible causes, if any (e.g., electrolyte disturbance)
  - Try vagal maneuvers
  - Establish vascular access
  - Administer adenosine intravenously. Adenosine 0.1–0.2 mg/kg is given as a rapid IV push followed immediately by a saline flush as the half-life of the drug is only a few seconds
  - Amiodarone 5 mg/kg IV over 20 min may be used in case of recurrence after initial response to adenosine.
- In an unstable SVT, the steps of management are:
  - Support ABCs and start oxygen
  - Attach to a monitor
  - Obtain a 12 lead ECG, if possible
  - Synchronized cardioversion 0.5–1 joules/kg for the first dose, followed by 2 joules/kg
  - If vascular access is present, administer adenosine
  - In case of response followed by reverting to SVT, administer IV amiodarone.

Abbreviations: ABC, airway, breathing, circulation; SVT, supraventricular tachycardia.

**Torsades de pointes** This is a polymorphic VT wherein the amplitude and the polarity of the QRS complexes change and gives an appearance of rotating around the isoelectric line of the ECG. This is associated with hypomagnesemia and long QT syndrome, congenital or acquired due to drug toxicity with class IA antiarrhythmics (e.g., quinidine, procainamide) or class III antiarrhythmics (e.g., sotalolol, amiodarone). This arrhythmia is treated with IV magnesium sulfate 25–50 mg/kg slow IV over 10–20 min.

**Reversible causes** Several reversible causes can also lead to tachycardia and tachyarrhythmias. These include the Hs and the Ts; i.e., Hs—hypovolemia, hypoxia, hypokalemia or hyperkalemia, acidosis ( $H^+$  ion), hypoglycemia, hypothermia and the Ts—toxins, tension pneumothorax, tamponade (cardiac), thrombosis (coronary/pulmonary) and trauma (hypovolemia). Look for these and manage accordingly.

### Vagal Maneuvers

Normally, heart rate decreases on vagal stimulation and this is more pronounced in infants and young children. In children

with SVT, vagal stimulation and its attendant effect on heart rate may terminate the arrhythmia. Hence, this can be tried in stable children with SVT. The following maneuvers increase vagal tone:

- Ice can be placed in a small plastic bag or a glove and held against the upper half of the face for an infant or a young child. Take care not to occlude the nose or mouth as that would interfere with breathing. Do not press hard on the eyes as this can cause retinal injury.
- An older child can be asked to perform a Valsalva maneuver by blowing through a narrow straw.
- Carotid sinus massage can be performed safely in older children.

### Synchronized Cardioversion

Synchronized shocks are delivered using a defibrillator to coincide with the R wave of the patient's QRS complex. This prevents delivery of the shock during the T wave which could otherwise result in progression to ventricular fibrillation. The energy dose required is 0.5–1 joule/kg for the first dose; if there is no response, repeat with a dose of 2 joules/kg. Electrical cardioversion is painful. Whenever possible, obtain vascular access and administer procedural sedation and analgesia before cardioversion. However, in a hemodynamically unstable patient, this should not delay cardioversion.

The algorithm for management of tachycardia is provided in **Flow chart 2**.

## CARDIAC ARREST

Cardiac arrest is the cessation of blood circulation as a result of absent or ineffective mechanical activity of the heart. As blood circulation stops, the perfusion of all the organs stops and these organs abruptly stop functioning. The patient quickly becomes unconscious and stops breathing. If not rapidly reversed, cardiac arrest leads to the death of the patient. The child is unresponsive, with apnea or gasping respiration and no detectable pulse.

### Causes

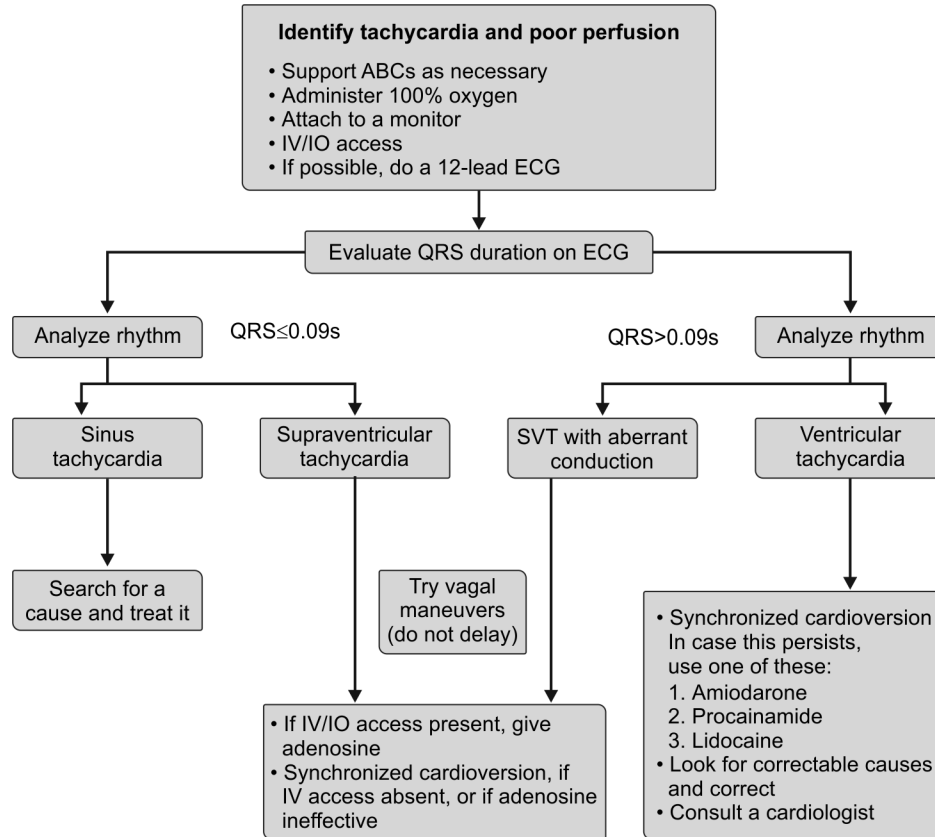

When shock or respiratory failure is untreated, it progresses to cardiopulmonary failure leading to cardiac arrest. Most cardiac arrests in children are due to this final common pathway, which is referred to as hypoxic or asphyxial cardiac arrest. A small proportion of cardiac arrests (10–15%) occur primarily due to cardiac rhythm disorders (ventricular fibrillation or pulseless VT) as a result of underlying predisposing conditions such as congenital long QT syndrome, hypertrophic cardiomyopathy or anomalous coronary artery. Several reversible causes have been identified which could lead to cardiac arrest and also prevent response to resuscitative measures. These include the Hs and the Ts, as mentioned above.

### Cardiac Rhythms During Cardiac Arrest (Figs 3A to C)

When a patient with cardiac arrest is attached to a monitor, one of the following arrest rhythms is found: (i) asystole; (ii) pulseless electrical activity (PEA); (iii) ventricular fibrillation; and (iv) pulseless VT.

**Asystole** Absence of all cardiac electrical activity, characterized on ECG by a flat line.

**Pulseless electrical activity** Organized electrical activity is seen on the ECG, but there is absence of a pulse; this is also referred to as electromechanical dissociation. The ECG often shows a slow rate with wide QRS complexes. If left untreated, then rhythm

**Flow chart 2** Management of pediatric tachycardia with cardiopulmonary compromise

deteriorates to asystole. PEA is often caused by the reversible causes, the Hs and the Ts.

**Ventricular fibrillation** Disorganized and chaotic electrical activity in the form of undulations of the baseline is seen. Since there is no organized contraction, the heart is unable to pump blood and pulses are not palpable.

**Pulseless ventricular tachycardia** VT without a pulse is managed differently and is one of the arrest rhythms.

Asystole and PEA are the most common initial rhythms seen in pediatric cardiac arrest. VF or pulseless VT require defibrillation in the management and are referred to as *shockable rhythms*. Survival and outcome in children with *shockable rhythms* is better than for children with asystole or PEA.

## Management

The aim of management is to restore a spontaneous and perfusing cardiac rhythm. The steps of management are outlined in **Box 2**. The management algorithm for cardiac arrest is shown in **Flow chart 3**.

**High quality CPR** The first and most important aspect of management of cardiac arrest is to start high quality CPR. To recapitulate, high quality CPR includes chest compressions of adequate depth ( $\geq 1/3$ rd of the anteroposterior diameter of the chest), a rate of approximately 100/min, allowing complete chest recoil, minimal interruptions of chest compressions, compression: ventilation ratio of 15:2 with two rescuer CPR till such time as an advanced airway is in place and subsequently without interruptions for ventilations. Every 2 min, CPR is interrupted for rhythm check. Chest compressions are tiring

and hence the compressor should be rotated after every 2 min or 5 cycles. Excessive ventilations interfere with venous return and are detrimental; hence this should be avoided. Interruptions of chest compressions for rhythm check and/or rotation of compressor should not take longer than 10 sec.

**Defibrillation** Since there is no organized cardiac activity, synchronization while delivering the shock is not required. An unsynchronized shock is defibrillation. The first dose is 2 joules/kg body weight; subsequent doses are 4 joules/kg. Higher doses of up to 10 joules/kg (maximum being the adult dose) may be given. When defibrillation is ineffective, administer adrenaline and repeat defibrillation. The second drug which may be given is amiodarone; this may be repeated up to 2 times for refractory VF/VT.

**Drug delivery during CPR** Drugs should be administered during compressions, preferably either just before or after delivering the shock. The compressions circulate the drug before the next rhythm check. **Table 3** provides the dosage of various drugs used during CPR.

**Advanced airway** While it is not essential to use an advanced airway during resuscitation, it is always preferred. The rate of ventilation should be around 8–10 breaths/min. Excessive inflation should not be used. It is preferable to confirm ET tube placement with capnography; this would help in monitoring the quality of compressions too.

**Hs and Ts** The importance of these reversible causes cannot be overstated. Each of these conditions should be ruled out. Often, nonresponse to adequate resuscitation efforts is due to one of the Hs or Ts. A careful evaluation for each of these is essential.

**Figures 3A to C** Arrest rhythms: (A) Asystole; (B) Pulseless electrical activity; and (C) Ventricular fibrillation

#### BOX 2 Management of cardiac arrest

- High quality CPR
- Provide oxygen
- Assess rhythm
- Establish vascular access
- In case of a non-shockable rhythm, administer adrenaline IV/IO and repeat every 3–5 min. Look for the Hs and Ts and treat any reversible cause
- In case of a shockable rhythm, obtain a defibrillator and deliver shock at a dose of 2 joules/kg. Resume CPR soon after delivering the shock. In case of persistent shockable rhythm, repeat defibrillation with a higher dose of 4 joules/kg. If there is no response to defibrillation and the rhythm continues to be shockable, administer epinephrine and then amiodarone and repeat defibrillation
- Consider advanced airway whenever feasible and as soon as an experienced person is available.

Abbreviation: CPR, cardiopulmonary resuscitation.

#### Determinants of Outcome and Decision to Terminate Resuscitation

The following factors portend a favorable outcome after cardiac arrest: witnessed arrest, bystander CPR and a short interval from arrest to resuscitation by professionals. There are no definite guidelines

as to when to stop resuscitation efforts. The reason for the cardiac arrest, the presence of any underlying chronic disease, time taken to start resuscitation and the circumstances where the resuscitation is being done would all influence when the resuscitation efforts are stopped. In certain circumstances, resuscitation efforts should be continued for a prolonged period, such as hypothermic patients, drug intoxication and refractory VF or VT.

#### Team Concept

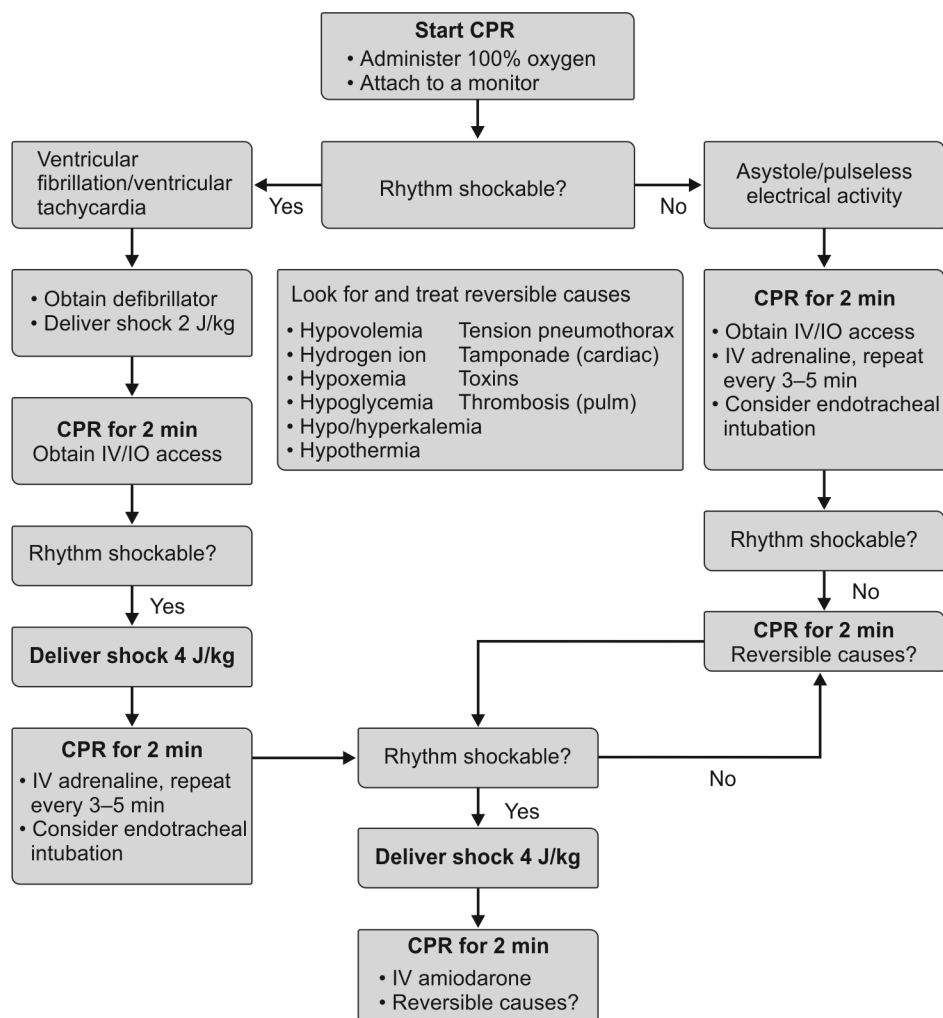

During the resuscitation of a sick child, many tasks have to be performed in a time-bound and systematic manner; also, health-care providers tend to get anxious and the situation often becomes chaotic. It is desirable to perform all actions in a coordinated manner and having trained team members designated for the necessary actions greatly enhances the quality of resuscitation. A team of at least five members is desirable with the roles of airway management and providing ventilation, chest compression, venous access and drug delivery, placing the patient on the monitor and monitoring and providing defibrillation; all supervised by a team leader.

#### Post-resuscitation Care

In the event of a successful resuscitation from cardiac arrest and return of spontaneous circulation, the child is vulnerable to suffer cardiac arrest again and several factors influence long-term

**Flow chart 3** Management of pediatric cardiac arrest  
(Call for help and ask for emergency resuscitation drugs)

outcome, i.e., survival and quality of life. Post-resuscitation care is one of the most important aspects which determine the long-term outcome. Hence, it is equally important to provide optimal care at this time. A systemwise evaluation, monitoring and support of all organ systems form the basis of post-resuscitation care. The most important aspects are listed here:

- Maintain normothermia; avoid hyperthermia at all costs. The role of inducing moderate hypothermia in children is not yet well established.
- Maintain normoglycemia; hyperglycemia is deleterious.
- Ensure adequate ventilation. Maintain normal levels of  $\text{PaCO}_2$  and  $\text{PaO}_2$ . Hyperoxemia is harmful; hence after the resuscitation phase, oxygen should be titrated to maintain a pulse oximeter  $\text{SO}_2$  around 94–95%. Hyperventilation compromises cerebral blood flow and is deleterious;  $\text{PaCO}_2$  levels should be maintained around 35 mm Hg.

- Shock is often present in this phase. Treat and correct shock aggressively with volume resuscitation and vasopressor infusions as required. Adrenaline infusion is the drug of choice in the post-resuscitation phase. An adequate mean arterial pressure is required to maintain adequate cerebral perfusion. Myocardial depression is common and should be addressed appropriately.
- Optimize electrolytes, especially sodium. Maintain sodium levels around 140 mEq/L.
- Look for and treat seizures aggressively.
- Administer prophylaxis for gastric stress ulcer bleeding.
- Monitor and maintain urine output.
- The child should be managed at a center where meticulous attention to all these details is given. A pediatric intensive care unit equipped to provide this level of care is preferred.

**Table 3** Drugs used during resuscitation

Drug	Dose (IV/IO)	Concentration available	Comments
Adenosine	0.1–0.2 mg/kg	3 mg/mL	Use rapid bolus using two syringe technique
Adrenaline/Epinephrine	0.01 mg/kg/dose or 0.1 mL/kg of 1:10,000	1 mg/mL (1:1000)	For IV/IO, 1:10,000 conc. is used; for ET dose, 1:1000 conc. is used
Amiodarone	5 mg/kg over 20 min	50 mg/mL	May need to be continued as an infusion
Atropine	0.02 mg/kg, minimum dose is 0.1 mg	0.6 mg/mL	Maximum dose 0.5 mg for a child
Calcium chloride	20 mg/kg/dose slow IV (0.2 mL/kg)	100 mg/mL	Administer with ECG monitoring. (In case of calcium gluconate, the dose is 0.6 mL/kg)
Glucose	0.5–1 g/kg/dose	D10W (0.1 g/mL) D25W (0.25 g/mL) D50W (0.5 g/mL)	In case of hypoglycemia, after bolus, ensure adequate glucose infusion rate
Lidocaine	1 mg/kg slow IV	20 mg/mL	Needs to be followed up with infusion
Magnesium	25–50 mg/kg slow IV over 10–20 min	500 mg/mL	Drug of choice for <i>torsades de pointes</i>
Procainamide	3–6 mg/kg over 5 min	100 mg/mL	May repeat every 5–10 min to a maximum of 15 mg/kg
<b>Vasoactive drug infusions*</b>			
Drug	Preferred dose range	Differential actions at different infusion doses (mcg/kg/min)	Comments
Adrenaline	0.05–1.0 mcg/kg/min	0.05–0.3: Inotropic action predominates 0.3–2.0: Vasopressor action + inotropy > 2.0: Vasopressor alone	Drug of choice for cold shock Increases myocardial oxygen demand and causes lactic acidosis
Dopamine	2–20 mcg/kg/min	2–10: Inotropic action predominates > 10: Vasopressor action	Usually the first vasoactive started for shock.
Dobutamine	2–20 mcg/kg/min		First choice among the inotropes Volume optimization required before starting infusion
Noradrenaline	0.02–2 mcg/kg/min		Drug of choice for warm shock
Milrinone	0.25–0.75 mcg/kg/min	50 mcg/kg over 60 min can be used as a bolus	Is an inodilator Lusitropic action predominant May need volume bolus before starting infusion
Vasopressin	0.2–2 milliunits/kg/min		Useful for warm shock Limited pediatric literature

\*All vasoactive infusions are preferably given through a central venous line. Adrenaline, dopamine, noradrenaline and vasopressin infusions can all cause skin necrosis, if extravasation occurs. Action of the drugs is also faster, if infused through a central vein.

### IN A NUTSHELL

1. Cardiac arrest in the pediatric patient is a culmination of progressive respiratory failure or shock, or rarely, a combination of the two.
2. Early, aggressive, high quality CPR improves the outcome from cardiac arrest.
3. Prevention of cardiac arrest is important and forms the first and most important link in the pediatric *chain of survival*.
4. Cardiac arrhythmia as a cause of cardiac arrest occurs in only 8–10% of pediatric cardiac arrests; however, in such patients, early defibrillation is required.
5. The most common cause of bradycardia is hypoxemia; hence the management of bradycardia is to ensure adequate ventilation and oxygenation.
6. Tachycardia is classified into *narrow complex* and *wide complex* based on the duration of the QRS complex.
7. Sinus tachycardia is the most common tachycardia and this occurs in response to a wide variety of stimuli including fever, pain, anxiety, dehydration, etc.
8. Ventricular tachycardia is inherently an unstable rhythm and needs immediate attention.
9. In a patient with cardiac arrest, the rhythms that can be found include asystole, PEA (organized rhythm in the absence of mechanical contractions), ventricular fibrillation and ventricular tachycardia.
10. There are a number of *reversible causes* of cardiac arrest and the response to resuscitation is suboptimal unless these are attended to. These include several metabolic and electrolyte disturbances, toxins and tamponade from pneumothorax or pericardial effusion.

# Section 8 INTENSIVE CARE

**Section Editor** Rakesh Lodha

## Chapter 8.1

### Pediatric Intensive Care Unit

*Dhiren Gupta, Neeraj Gupta, Manpreet Sethi*

Pediatric critical care has come a long way over the past several years, not only in the developed Western countries but also in the developing world. This in turn has led to the establishment of various state-of-the-art pediatric critical care units in all parts of the world. Better understanding of the pathophysiology of life-threatening conditions combined with great technological advances has made it possible to monitor and treat critically sick children in the present time. Needs for pediatric critical care are very different from that of adult critical care and, thus, critically ill children are best managed by personnel specially trained to manage such children. This has resulted in the demand for separate pediatric critical care specialists. American Board of Pediatrics recognized the fact in 1985 by setting up a separate speciality of pediatric critical care.

Level 3 pediatric intensive care unit (PICU) must be adept in handling various complicated medical, surgical and traumatic emergencies encountered in children of all ages other than newborns, though a multidisciplinary approach is required. Level 2 PICUs were defined as units capable of providing interim care and transport of critically ill children who require transfer to higher centers and to efficiently manage children with disorders of moderate complexity, thus avoiding their long-distance transfers. However, whatever the level of PICU, the same standards of quality care should be applicable to both, and a good communication system must exist between the two for timely referral of sick patients.

#### ORGANIZATION AND ADMINISTRATION

Pediatric intensive care unit should be a separate acute care unit that provides specialized tertiary level pediatric critical care. It may serve as a regional referral center for critically ill children. Intensive care in a PICU should be provided only by providers who are capable of managing complex pediatric medical and surgical emergencies. The key team should include pediatric medical and surgical specialists, nurses, physiotherapists, pharmacists, medical social workers, dieticians, etc.

#### PHYSICAL DESIGN AND FACILITIES

There are certain mandatory requirements while designing a PICU:

1. For the sake of patient and staff safety, the access to the PICU should be strictly monitored and there should be no thoroughfare to other departments through PICU.
2. The PICU should be closely located to the lift area for easier patient transport and also to the duty doctor's room for the

prompt clinical response and also be close to the family waiting areas.

3. Although the manned (physically or electronically) entry and exit points should be there, emergency exit points should also be provided.
4. Future adaptability and expansion and utilization of space, equipment should be taken into consideration.

#### AMBIENT AND ATMOSPHERIC FEATURES

Specific guidelines as regards to noise and lighting in PICU have been developed for smooth functioning of unit. The permissible noise level as laid down by WHO is less than 45 decibels (dB) in the day and less than 20 dB at night. Sound proofing of walls and ceilings by using materials of high-sound absorption capabilities should be provided for. Overhead lighting should be 20 foot candles whereas spot lighting when required for certain procedures should be of 150 foot candles strength. Wherever possible, access to outside natural light is preferred. Appropriate color schemes and good interiors lend an additional friendliness to the environment of PICU. Every PICU should have a controlled airflow to prevent and minimize airborne infections.

#### FLOOR PLAN

While designing PICU, provision for several distinct rooms should be made. Apart from the patient area, a separate area is required for drug and parenteral nutrition preparation that should meet strict sterility codes. A family counseling room separate from the patient area is necessary to update and discuss the patient status with the family. Also wherever possible, a satellite pharmacy within the PICU is desirable for providing emergency medications.

#### BEDSIDE FACILITIES

It is recommended that a PICU should have 8–12 rooms. Having less than 6 beds is not cost-effective and when beds are more than 14, the quality of care may suffer. A minimum of 250 square feet area for individual rooms in PICU and 225 square feet area per patient forward type bed is mandatory. Also, the distance between two beds must be at least 5–8 feet. Provision for 1 or 2 isolation rooms for care of immunocompromised children or children with infectious disease must be kept. The head of each bed should be readily accessible for emergency airway management. In a view of better workspace organization, equipment columns that are suspended from the ceiling are most useful (**Fig. 1**). To ensure proper patient privacy, walls or curtains should be provided in between the beds. There should be enough space between the beds to perform required procedures like central line insertion, chest tube placement or to perform portable X-ray, ultrasound, echocardiography, etc. Two suction outlets, two oxygen outlets and two air outlets must be provided on the walls along with two electrical outlets. Bed design should ensure railings on both the sides to prevent the child from falling. Apart from the above, there should be a provision for an emergency alarm button in case of

**Figure 1** Equipment stands suspended from ceiling

any emergency needing prompt action. Finally, emergency power backup and gas supply at each bedside are also essential.

## HAND HYGIENE AND PREVENTION OF INFECTION

Strict measures for prevention of transmission of infections in PICU need to be instituted. Those include providing alcohol-based antimicrobial hand rub solution at every bed for use in between the patient examination. An operation theater type sink using elbow or foot operated water supply and antiseptic soap solution source at a conveniently and unavoidable location in the PICU where the usual handwash should take place. Apart from this, masks, caps and gowns should be worn by all people entering the PICU at any time.

## PERSONNEL

### Medical Director

A medical director should be amongst the personnel involved in the patient care in PICU. His responsibilities would include patient triage, implementation of policies and procedures, coordination of multiple consultants, duty roster management so that some qualified pediatrician (resident/fellow/attending staff) is always available round the clock. Apart from clinical services, he must be in charge of in-service education and also function as arbiter and patient advocate.

### Physician Staff

Although it is desirable to have full-time pediatric intensivist in the PICU, due to scarcity of resources in countries like ours, the minimum qualification of an in-house physician should be that of senior postgraduate in pediatrics or anesthesia for a Level 1 PICU.

### Nursing Staff

The nurse in charge of PICU should have substantial expertise and experience in pediatric care. Her duties include ensuring a safe practice environment, adequate and appropriate staffing and taking care of supplies and equipment in the PICU. Nurses on duty should be well versed with pediatric critical care nursing through regular teaching and orientation programs and should undergo complementary reviews at regular intervals.

## Ancillary Support Personnel

Other personnel required at various levels of pediatric critical care are the backbone and include orderlies, nursing attendants, technicians, storekeepers, sweepers, etc.

## LEVELS OF CARE

### Level 3 (Highest)

All patients with multiple organ failure of an immediate life-threatening nature who require complete assistance, such as hemodynamic support, ventilatory support, renal replacement therapy as well as other drug or device-related organ support fall in this category. Provision for one nurse per patient is required in Level-3 care.

### Level 2 (Intermediate)

Patients with single organ failure who need monitoring and drug or device-related support fall in this category. The acceptable nurse-patient ratio is 1:2.

### Level 1 (Lowest)

Patients with some signs of organ dysfunction requiring continuous monitoring and some drug- or device-related support fall in this category. They are considered to be at risk for developing an acute organ failure. Even patients who are recovering from one or two organ dysfunction are included in this category. Here, three patients may be attended by one nurse.

## HOSPITAL FACILITIES AND SERVICES

No PICU can run efficiently without an excellent support from emergency department. In all hospitals with PICUs, the emergency department should be staffed with physicians who are experienced in pediatric resuscitation. Support from other services like pediatric surgery, blood bank, radiology, laboratories, pharmacies and diagnostic services should be readily available.

## Drugs and Equipment

There should be prompt availability of all drugs and equipment required for resuscitation and advanced life support and monitoring for any patient in the PICU. Along with the life support equipment, devices for diversion and entertainment should be available for children who are conscious.

## Crash Cart

A crash cart containing emergency drugs, defibrillation and portable monitors should be readily available and accessible. All emergency drugs and equipment should be systematically arranged in the cart and an easy-to-understand checklist should be available.

## Prehospital Care

Since quite often patients in the PICU are retrieved and transported from the site of injury or from another hospital, an effective and integrated global system of mobile communication within the PICU is desirable. Moreover, the PICU should be provided with multiple telephone lines to ensure that no outside calls are missed even at busy times. It is imperative to have rapid access to poison control cell.

## Quality Improvement

Strict multidisciplinary quality control must be employed by the PICU for quality assessment purposes. Observed and predicted morbidity and mortality rates for a particular level of severity of illness must be assessed by objective methods and outcomes between similar units must be compared.

## COMMUNICATION WITH THE FAMILY

The family of patient in PICU should form an important part of patient care. The family should be updated about the patient's status regularly. Information regarding current patient status, nature of illness, possible complications, and course in the next 24 hours, a detailed patient care plan, planned investigations and procedures, the anticipated duration of PICU stay and expenses must be discussed not only at admission to PICU but also daily and recorded appropriately in the case sheet.

## TRAINING AND CONTINUING EDUCATION

There should be a written plan for training all health-care professionals about the basics of pediatric critical care. Apart from this, there should be a well-designed teaching program for all residents, postgraduates, etc., working in the PICU covering most aspects of pediatric critical care. This can be achieved through bedside teaching, formal lectures, presentations and journal clubs. All health-care workers looking after critically ill children should be encouraged to attend regional and national level meetings concerning pediatric critical care. Fellowship programs should be started in sufficiently busy tertiary level PICUs. Research forms an essential and integral part to understand disease and its management. It must be undertaken within the PICU in an attempt to improve techniques and treatments that may in turn improve the overall mortality and morbidity.

## SPECIAL CHALLENGES

### Role of Leader in PICU

The administrative hierarchy should be clearly outlined while setting up the organizational structure of the PICU. The leader of the team should be one who is well-accepted and respected not only by people in pediatric critical care but also other specialties and who possesses good skills in patient management apart from being good at organization and mentorship. His/her main role is to streamline the multidisciplinary teamwork and maintain effective communication to ensure smooth functioning of the PICU. Concrete policies and principles need to be laid down while setting up a PICU for effective functioning and best patient care. This includes a written set of protocols and policies toward patient care to minimize errors. A common goal in the best interests of the patient care is concise and clear communication between all members of the team.

### Dealing with Complications

It is not uncommon to encounter complications and adverse events among the critically sick children during their stay in PICU. These may occur by chance, or due to the underlying disease itself, technical failures or human errors. Such events, when they occur, should not result in blame games among the health-care providers. Instead, they should be addressed with constructive criticism and discussed and analyzed in detail through audits and meets so that appropriate changes and actions can be made to prevent such events in the future.

## DECISION-MAKING IN PEDIATRIC INTENSIVE CARE UNIT

Ideally all major decisions regarding patient care are made after multidisciplinary clinical rounds. These must be documented legibly and then communicated to the primary caregivers who execute the orders or plan. However, in cases of emergency, the caregiver on duty should be given full authority to take his/her own decisions that he or she feels is most appropriate at the time. Also such good decisions that have improved patient outcome should be appreciated by the seniors.

## COST CONTAINMENT

Good quality care at the most effective cost should be the goal of any successful intensive care team and, therefore, all cost containment strategies should be employed.

## INDIAN SCENARIO

The difference in pediatric intensive care between developed and developing worlds are still significant (**Figs 2 and 3**). Poor space allocation, limited electricity supply, lack of effective oxygen supply and even of clean water coupled with infection, poor nutrition and sanitation along with poor primary health care including immunization account for the differences in outcomes of critically sick children between the developed

**Figure 2** Bedside facility of a pediatric intensive care unit in western world

**Figure 3** Bedside facilities in an Indian pediatric intensive care unit

and developing world. Moreover, financial and budget issues challenge the sustainability of PICUs. Additional challenges are nonavailability of pediatric subspecialists and lack of adequate diagnostic facility and equipment, etc. Also, poor retrieval and transportation of critically ill patient add to higher mortality rates. Despite all these constraints, India has seen a rapid growth in the field of pediatric intensive care over the past few years. PICUs' bedside facilities have improved remarkably over the last decades with better performance and enhanced family satisfaction.

### IN A NUTSHELL

1. Needs for pediatric critical care are very different from that of adults and, thus, critically ill children are best managed in a separate PICU by personnel specially trained to manage such children.
2. Though the setting up and running of pediatric intensive care facilities in developing countries is a difficult and challenging task, the very exigencies of developing countries necessitate such establishment.
3. There are certain mandatory requirements while designing a PICU. Based on facilities available, a PICU is labeled as Level 1 to Level 3 (highest).
4. High incidence of infections, malnutrition, chronic diseases, etc. necessitates a robust pediatric intensive care infrastructure.

## Chapter 8.2

# Shock

Srinivas Murthy, Niranjana Kissoon

Shock is inadequate oxygen delivery or impaired oxygen utilization to meet the metabolic needs of the body. It has a variety of inciting causes and is the common final pathway for death and disability in children. This chapter will discuss aspects of the physiology and the classification of shock, as well as provide an overview of clinical assessment tools to differentiate etiologies and dictate initial management strategies.

## PHYSIOLOGY

Shock is an exceedingly complex syndrome that, if uninterrupted, leads to irreversible cellular and tissue damage and death. An insufficient oxygen supply to tissues results in cellular anaerobic metabolism and inefficient energy generation, leading to cellular acidosis and organ dysfunction. It is this vital organ dysfunction that will ultimately lead to death.

Adequate tissue oxygenation is dependent on a variety of factors that affect both the supply and demand of oxygen. Total blood volume, cardiac output or blood pressure contribute to oxygen supply, while impaired cellular function, such as seen in severe sepsis, disrupts oxygen utilization. Any combination of factors resulting in oxygen demand exceeding oxygen supply will lead to shock. While the presence of shock is sometimes obvious, a measure of the relative contributions of the contributing variables relating to delivery and consumption are important to determine an approach to treatment.

## Determination of Tissue Oxygen Delivery

Oxygen delivery ( $DO_2$ ) to tissues is dependent upon two main components—the arterial oxygen content and the cardiac output. Oxygen delivery is the amount of oxygen delivered to tissues of the body per minute, and is typically in the range of 600 mL/min/m<sup>2</sup> in times of rest. As oxygen content consists primarily of oxygen carried by hemoglobin molecules, blood oxygen content can often be predicted by examining the saturation through pulse oximetry, assuming a normal hemoglobin concentration.

The amount of blood flow, and hence cardiac output, can be calculated by determining the amount of oxygen delivered and consumed through a tissue bed as described using the Fick principle (see Equation 4, **Table 1**). However, this approach is impractical for clinicians because measurements of oxygen consumption are labor and equipment intensive. However, a very rough estimate of cardiac output trends can be determined through oxygen saturations from the arterial and mixed venous circulations and assumed constant oxygen consumption (see Equation 5, **Table 1**).

## Determination of Tissue Oxygen Consumption

Tissue oxygen consumption ( $VO_2$ ) is typically independent of tissue oxygen delivery at rest, with oxygen delivery vastly exceeding oxygen consumption (**Fig. 1**). In times of health, there are numerous compensatory mechanisms to ensure that this situation is maintained. For instance, cardiac output is easily augmented through catecholamines and other stress responses; blood flow is redistributed to vital organ systems, namely the brain, heart, and kidneys; and microcirculatory alterations enhance tissue extraction through recruitment of small capillary networks and locally-released inflammatory mediators. In shock, these compensatory mechanisms are overwhelmed, and oxygen consumption becomes dependent upon oxygen delivery. This leads to anaerobic metabolism as discussed above.

As evidenced by equations 4 and 5 (**Table 1**), the use of mixed venous saturations can be useful in clarifying these complex relationships. In normal situations, the ratio of oxygen consumption to oxygen delivery is approximately 0.2–0.3, producing a mixed venous saturation of 70–80%, assuming a normal arterial saturation. In shock states, when oxygen consumption is dependent upon oxygen delivery, this oxygen extraction ratio may increase, producing a mixed venous saturation below 50%, which indicates severe circulatory compromise and impending anaerobic metabolism. Alternatively, if oxygen extraction is limited by a cellular inability to extract oxygen, such as during sepsis, the mixed venous saturation may be abnormally high, with an oxygen extraction ratio of 0.1 (**Table 2**).

## CLASSIFICATION

Given the above, oxygen delivery can be inadequate when any one of three conditions is met: (1) inadequate tissue blood flow; (2) inadequate oxygen or substrate delivery; or (3) inadequate oxygen extraction. However, in most instances, an isolated condition rarely exists and there is a considerable overlap of contributors.

**Table 1** Important hemodynamic formulas for the child in shock

1. Oxygen delivery = (Cardiac output) × (Oxygen content) $DO_2 = CO \times CaO_2$
2. Cardiac output = Heart rate × Stroke volume $CO = HR \times SV$
3. Oxygen content = (Hemoglobin × oxygen saturation × 1.34) + (0.003 × arterial oxygen tension) $CaO_2 = Hb \times SaO_2 \times 1.34 + 0.003 \times PaO_2$
4. Oxygen consumption = Oxygen delivery × Oxygen extraction (Modified Fick equation) $VO_2 = DO_2 \times O_2ER$
5. Oxygen consumption = Cardiac output × (Arterial – Venous oxygen content) $VO_2 = CO \times (Ca - Cv)$

**Figure 1** Oxygen delivery as it relates to oxygen consumption. At the inflection point, oxygen consumption is dependent upon oxygen delivery, and tissue dysoxia occurs

**Table 2** Causes of a low mixed venous saturation

1. Low arterial saturation
2. High oxygen consumption
3. Low cardiac output
4. Low hemoglobin concentration

Inadequate tissue flow consists of inadequate cardiac output or inadequate circulating volume. When there is inadequate cardiac output due to myocardial failure, cardiogenic shock ensues due to insufficient blood flow to tissues. When there is insufficient circulating blood volume because of dehydration or blood loss, hypovolemic or hemorrhagic shock results. Similarly, shock results with a loss of *effective* vascular volume, such as in anaphylaxis or after acute spinal cord resection, where systemic flow is inadequate.

Recalling the formula for arterial oxygen content, it is clear that acute respiratory failure will lead to shock, if hemoglobin molecules have been desaturated for enough time to lead to tissue hypoxia. Additionally, acute hemolysis leading to a rapid loss of oxygen carrying capacity will lead to a shock state. Finally, conditions such as carbon monoxide poisoning or methemoglobinemia may lead to a shock state, as oxygen delivery will be substantially impaired.

When oxygen delivery is adequate, extraction is crucial for maintaining tissue homeostasis. In septic shock, an inability of tissues to extract the needed oxygen due to microvascular changes and mitochondrial dysfunction is often a contributing factor.

In addition to classification based upon physiologic derangements as outlined above, shock can be classified by its stage. Compensated shock refers to early disease, where blood pressure is maintained, tissue perfusion is mostly adequate, and there are subtle signs of shock, such as tachycardia, tachypnea, altered capillary refill and mild lactic acidosis. This can progress to decompensated shock, where compensatory mechanisms are overwhelmed and clear signs of organ dysfunction exist due to dysoxia and progressive acidosis. Blood pressure will often suffer in this stage of shock, further compromising tissue perfusion, with progressive multiple organ failure. Irreversible shock occurs when there is widespread cellular and organ dysfunction, leading to death, in spite of intensive medical therapies.

## MAJOR ETIOLOGIES

Shock in children can be due to a variety of causes, with frequent overlapping of the major categories of cardiogenic, hypovolemic, and distributive shock, which can sometimes be differentiated by hemodynamic parameters (**Tables 3 and 4**). Myocarditis, rheumatic heart disease and unrepaired congenital heart disease are the major causes of childhood cardiogenic shock in Asia. Additionally, septic shock often presents with features of cardiogenic shock, and a serious bacterial infection must always be considered in the differential diagnosis.

**Table 3** Physiologic characterization of types of shock

	Cardiac output	Systemic vascular resistance	Mixed venous saturations
Cardiogenic	Low	High	Low
Hypovolemic	Normal	High	Low-Normal
Distributive	High	Low	Low-High

**Table 4** Major etiologies of shock

Cardiogenic	Direct myocardial injury—Ischemia, infection, inflammation High afterload—Pulmonary hypertension, severe aortic coarctation Inadequate diastolic filling—Cardiac tamponade, tension pneumothorax Inadequate heart rate—Sinus node dysfunction
Hypovolemic	Trauma, dehydration, burns
Distributive	Anaphylaxis, spinal shock, sepsis, adrenal insufficiency

*Hypovolemic shock* is secondary to either dehydration, where a total body fluid volume is depleted, without a significant decrease in oxygen carrying capacity, such as in diarrhea; or hemorrhage, where there is a loss in oxygen carrying capacity due to a major loss in red blood cell volume, in addition to the depletion in total body fluid volume. Signs of shock typically occur when more than 20–30% of blood volume has been lost.

Similarly, *spinal shock* is due to an inability to maintain sympathetic tone and systemic vascular resistance, leading to inadequate tissue blood flow, secondary to spinal cord injury and trauma. Anaphylactic shock also leads to an inability to maintain vascular tone, but due to the uncontrolled release of endogenous vasodilators.

*Septic shock* is often a combination of all classes of shock. There is often poor cardiac function due to septic cardiomyopathy, with poor tissue perfusion due to the massive inflammation and vasodilation caused by the severe infection. Finally, an inability to use delivered oxygen makes septic shock especially challenging to treat. The etiologies of septic shock are broad and dependent upon local epidemiology, with bacterial infections, dengue, malaria and fungal diseases all prominent (**Table 5**).

**Table 5** Major microbiologic etiologies of pediatric septic shock in Asia

Bacterial	Viral	Other

## CLINICAL FEATURES

The diagnosis of the child with shock is made clinically, through a rapid assessment of history, physical exam findings and ancillary tests. There is no one test that will differentiate shock from non-shock, but rather its diagnosis relies on astute clinical expertise to recognize a combination of signs and symptoms indicative of circulatory compromise.

## History

Despite the time-sensitive nature of management of the child with shock, documenting a focused history is crucial to better dictate management. Eliciting this history can occur concurrently with the initial evaluation and resuscitation and should focus on differentiating the potential causes of shock, as these may be difficult to determine just through a physical exam. Any history of prior illnesses or congenital anomalies, signs and symptoms of infections, or traumatic events must be inquired about. For neonates and infants, a maternal and birth history is helpful, as well as pre-existing symptoms of congenital heart disease.

## Physical Examination

The diagnosis and classification of shock can be tremendously clarified by a focused and efficient clinical exam. The practitioner must examine for signs of decreased organ or peripheral perfusion in a systematic way. As mentioned above, only vital sign abnormalities, such as tachycardia and tachypnea, are present in early, compensated shock, and these are major components of the criteria for the systemic inflammatory response syndrome (SIRS) (**Table 6**).

**Table 6** Systemic Inflammatory Response Syndrome Criteria

- Core temperature (measured by rectal, bladder, oral or central probe) of  $>38.5^{\circ}\text{C}$  or  $<36^{\circ}\text{C}$ .
- Tachycardia, defined as a mean heart rate more than two standard deviations above normal for age, or for children younger than one year of age, bradycardia defined as a mean heart rate  $<10$ th percentile for age.
- Mean respiratory rate more than two standard deviations above normal for age or mechanical ventilation for an acute pulmonary process.
- Leukocyte count elevated or depressed for age, or  $>10\%$  immature neutrophils.

As tissue perfusion becomes compromised, documenting neurologic status, capillary refill, and the presence of a central to peripheral temperature gradient are helpful. These can be simply determined by laying hands on the patient and obtaining a rough assessment of overall perfusion. Skin mottling, decreased peripheral temperatures and altered capillary refill are often the first signs of impending shock, and should be taken seriously as the first stages in screening for level of acuity. The physical exam can help differentiate the shock between *warm shock*, where there is vasodilation, and *cold shock*, where extremities are cold with widespread vasoconstriction as a result of sympathetic responses to maintain perfusion to vital organs. This differentiation can help with staging the severity of shock, as well as in determining an etiology and dictating management strategies.

Volume status can be determined through skin turgor and fontanel status, depending upon the age. Cardiac function is assessed through auscultation for third heart sounds and examination for signs of acute heart failure, such as rales and hepatomegaly. Hypotension is a very late stage finding in pediatric shock; one should not wait for development of hypotension to diagnose shock. In children, hypotension is defined as a systolic blood pressure less than the fifth percentile of normal for age (**Table 7**). Finally, any focal symptoms, such as signs of infection, neurologic abnormalities, or cutaneous findings that point to an inciting etiology must be quickly determined to better dictate therapy.

**Table 7** Low systolic blood pressures for age in children

Age	Normal
$<28$ days	$<60$ mm Hg
1–12 months	$<70$ mm Hg
1–10 years	$<70 + (2 \times \text{age in years})$ mm Hg
$>10$ years	$<90$ mm Hg

## LABORATORY INVESTIGATIONS

The arterial blood gas, including a lactic acid and base deficit, will help quantify the degree of tissue dysfunction, and can guide response to therapy. As mentioned above, mixed venous saturations, when taken from an appropriate site, can be extraordinarily useful, both in guiding therapy and determining an etiology. Individual markers of organ function, such as liver enzymes, renal markers, such as creatinine, and markers of endothelial dysfunction, such as coagulation profiles, are also useful for both the diagnosis and prognosis of shock. Documentation of the presence, or absence, of the SIRS is useful (**Table 6**). An echocardiogram should be obtained to document cardiac function and volume status, if readily available, and cultures and other diagnostic tests should be performed to help guide specific therapies, depending upon the clinical scenario.

## INITIAL MANAGEMENT

The initial management of the child with shock requires focused attention and constant re-evaluation of chosen strategies. Upon recognition of the child with shock, supportive measures should be immediately instituted.

### Supportive Care

Supportive care includes ensuring that the patient is monitored with continuous electrocardiography and pulse oximetry. Intravenous access should be urgently obtained, with intraosseous access as an option in the child with difficulty in cannulating peripheral veins. Urine output should be carefully documented with placement of a urine catheter and invasive blood pressure monitoring with arterial catheterization is recommended, where available. Along these lines, the patient should be transferred to the highest level of care readily available, in a safe and timely fashion. The overall goal of therapy for shock is to restore the oxygen deficit that has occurred. Respiratory support should be provided, including oxygen delivery via face-mask or nasal cannula as needed, to maintain adequate gas exchange and saturations. There is no role for providing supranormal quantities of oxygen in shock—this has been disproven, and is associated with an increased risk of oxygen toxicity.

In children with signs or symptoms of infection, appropriate antibiotics should be promptly administered, given strong data illustrating that delays in delivery of antibiotics associated with worsened outcomes in the adult patient with septic shock. The choice of antibiotics is dependent upon the individual patient and local epidemiology, and should be integrated into institutional protocols to ensure timeliness.

### Fluid Resuscitation

The traditional mainstay of shock management is in the restoration of circulating blood volume through the administration of intravenous fluids. Infusing fluids has the theoretically beneficial effects of augmenting cardiac output, and hence, oxygen delivery, through improving the preload, assuming that cardiac function is appropriate. Predicting which child should receive fluids, however, and how much to infuse, is difficult.

Children with distributive, septic shock are traditionally responsive to fluid, and can tolerate up to 60 mL/kg before noticeable pulmonary edema, while children in cardiogenic shock will likely tolerate very little fluid infusion. However, most children do not fall neatly into one of these categories, making decision-making regarding fluid administration very complex. The simple rule is that every child in shock should be considered for a fluid challenge, with constant re-assessment for signs of improvement. In regions where there is no accessibility to modern intensive care supports such as mechanical ventilators, fluid administration has been associated with harm in the child with acute febrile illness. The mechanism of this worsening is likely due to underlying cardiac dysfunction leading to cardiovascular collapse and chronic anemia leading to hemodilution. Hence, if there is rapid development of signs of cardiac failure or worsening shock, such as hepatomegaly, rales, or jugular venous distension, then fluid administration should be immediately ceased. Additionally, if one is in a setting where there is a high burden of malaria, chronic anemia, malnutrition or there is a lack of accessibility to mechanical ventilation, fluid administration should be used very cautiously in the child with shock.

Markers of improvement with fluid resuscitation should be constantly re-evaluated, such as heart rate, level of alertness, blood pressure and urine output. Peripheral perfusion can be used as a surrogate marker of adequacy of resuscitation, in the absence of quantitative markers. If there is minimal improvement on these

markers, then central venous cannulation should be performed, if available, for rapid infusions, central venous pressure monitoring and mixed venous saturation sampling.

### Crystalloids or Colloids

The type of fluid to be administered has been studied extensively, without any specific conclusions. Isotonic crystalloid solutions are the standard of care in most regions of the world, with normal saline being the most used fluid for the acute resuscitation of children with shock. Colloid solutions, such as 5% albumin or starch solutions, are less widely used, primarily due to their costs. Colloid solutions have the theoretical benefit of maintaining intravascular volume; numerous studies, however, have not proven a substantial benefit to colloid solutions for a variety of types of shock, when compared with crystalloid, with further studies ongoing. The current recommendations are to use isotonic crystalloid as the first-line fluid for the resuscitation of shock, regardless of setting or etiology, given its ease of access and safety data. Newer data on the use of chloride-poor solutions, such as Plasmalyte or Ringer lactate, are emerging, with some promise, although further study is needed. In children with shock and severe anemia (Hb < 5g/dL), acute blood transfusions will augment oxygen carrying capacity and should be the first line fluid for resuscitation.

### Ventilation

Additionally, intubation should be considered at this juncture, depending upon the clinical status and gas exchange parameters. Administering the sedation required for intubation, however, should be done cautiously, given the fragile hemodynamic state of children in shock. The use of noninvasive ventilation, such as with continuous positive airway pressure (CPAP) or BiPAP, for maintaining gas exchange has great promise, and has been used more and more frequently over recent years. This avoids the need for sedation, as well as decreases costs and the risks of nosocomial infections. There is also the benefit of augmenting cardiac output through positive pressure ventilation, given the frequent cardiac dysfunction present in children with shock. Hence, in the child in shock with ventilatory requirements, a trial of noninvasive ventilation is often warranted.

The mixed venous saturations and lactic acid levels have been used to help guide resuscitation during shock, with a target-mixed venous saturation of more than 70% and lactic acid level of less than 2 mmol/L. These numbers can be closely monitored during resuscitation, if available, to decide upon whether further fluid administration is indicated, as well as in monitoring cardiac output. The rate of rise of lactic acid in children with shock has been shown to be one of the most accurate predictors of a bad outcome. Interventions that result in a decline in mixed venous saturations should be modified so as to target a normal oxygen extraction ratio.

Regardless of institutional capabilities, a protocolized approach to the resuscitation of the child in shock has been shown to be effective in reducing mortality. This protocol should be tailored to each institution, depending on personnel and equipment available, and should include rapid deployment of the appropriate people, obtaining a diagnosis, monitoring of hemodynamic parameters, determining fluid responsiveness, and transferring the patient to the appropriate level of care (**Flow chart 1**).

### Vasoactive Agents

In patients who are fluid-unresponsive but remain with signs of shock, vasoactive agents are recommended. Vasoactive agents are those that assist in maintaining systemic perfusion through either vasopressor activity and maintaining blood pressure in the hypotensive patient; inotropic activity to augment cardiac output and oxygen delivery; or vasodilation to assist with cardiac output in the patient with

cardiogenic shock and adequate blood pressure. Many drugs used in current practice exert a combination of these effects, depending on the dose used (**Table 8**) and the resultant receptor activity.

The choice of first-line agents depends upon the physiology, and frequent titration of dose is required to optimize clinical response. The physiologic effect of different agents is dose-dependent, and practitioners must be aware of changes in drug activity with altered dosing. Additionally, the physiologic response to these agents is attenuated over time, and will often require progressive escalation or cycling of vasoactive agents to maintain optimal effects.

Dopamine exerts a variety of effects: at low doses, it acts predominantly at dopaminergic receptors located on the renal, coronary and cerebral vascular beds, causing vasodilation and increased perfusion. At increasing doses, it progressively stimulates beta-1, and then alpha-1 receptors, causing increased cardiac output and then vasoconstriction. Epinephrine initially acts at beta-1 receptors at lower doses, but then becomes a potent alpha-1 agonist at higher doses, potentially limiting the hoped-for inotropic effects.

It is important to remember that titration should not be targeted towards normalization of blood pressure, but rather to optimize oxygen delivery to major organs. Hence, following quantitative markers, such as mixed venous oxygen saturations and lactic acid levels are very useful. Additionally, neurologic status, capillary refill and urine output are all markers of response to vasoactive agents.

### The Malnourished Child

The malnourished child with shock is an especially challenging situation, and carries an especially high level of mortality. The rapid infusion of volume often precipitates cardiovascular collapse in these children, given the baseline poor cardiac function and co-morbid anemia. World Health Organization guidelines recommend very small fluid boluses, followed by early consideration of blood transfusion, although the administration of any fluid to the malnourished child is not without controversy. The very early use of vasoactive agents in the malnourished child with shock has been proposed by some authors, although this has not been adequately studied.

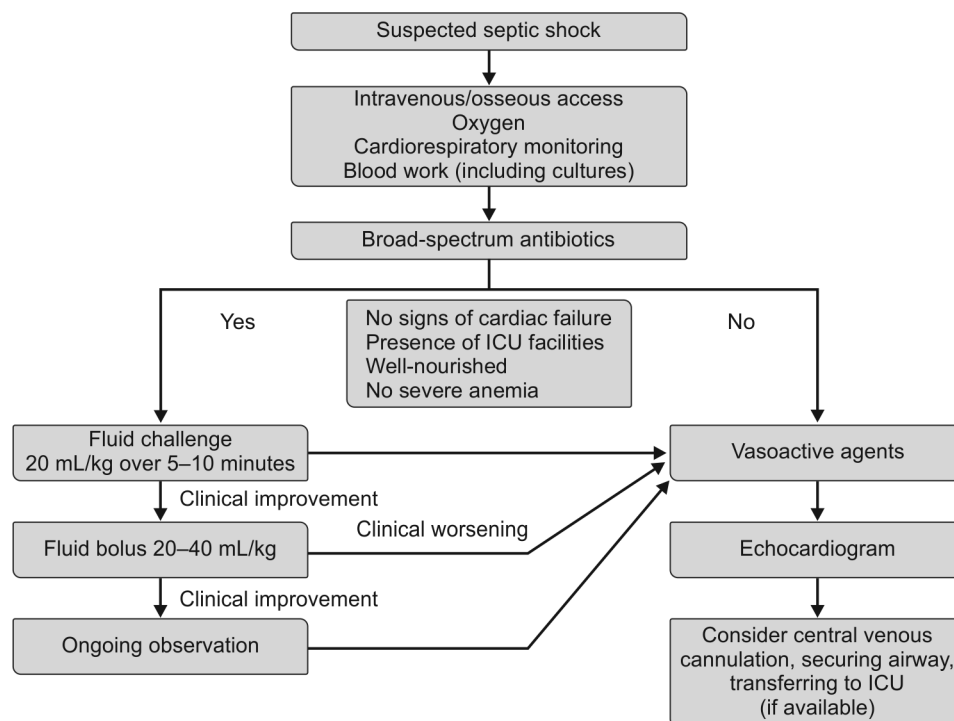

### Other Therapeutic Options

Other therapeutic options for shock are entirely dependent on the underlying etiology. In patients with hypovolemic shock, replacement of intravascular volume is the mainstay of therapy. This is the same for hemorrhagic shock, with volume replacement performed with blood. Transfusing children with shock, either sepsis or cardiogenic, and a hemoglobin less than 9 g/dL may be indicated to optimize blood oxygen content, although the data on this approach is limited and must be weighed against their individual fluid tolerance. As mentioned above, severe anemia (hemoglobin less than 5 g/dL) should be urgently transfused with packed red blood cells or whole blood, depending upon availability.

Corticosteroids for shock are controversial, with varying protocols as to the timing, dose and type of steroids to be administered. In shock that is resistant to catecholamine administration, it is recommended that 2 mg/kg of hydrocortisone are given in a timely fashion, followed by q 6h dosing of 1 mg/kg to supplement adrenal activity. Further study on the role of steroids is ongoing.

### Postresuscitation Care

Upon achieving some degree of stability, a variety of hospital-based therapies are important to ensure ongoing recovery. If there is a documented source of infection, this needs to be appropriately targeted with antibiotics, depending on microbiologic results, and removed, if possible, in the case of abscesses or empyema.

**Flow chart 1** Suggested algorithm for the initial management of suspected septic shock in children**Table 8** Vasoactive agents useful for children in shock

Agent	Receptor		Standard doses	Major clinical activity
	Alpha	Beta		
Norepinephrine	+++	+	0.02–0.2 mcg/kg/min	Vasoconstriction
Dopamine	++	++	5–20 mcg/kg/min	Vasoconstriction Inotropy
Epinephrine	+	+++	0.02–1 mcg/kg/min	Inotropy
Dobutamine	-	+++	5–20 mcg/kg/min	Inotropy Vasodilation
Milrinone	PDE-3 inhibition		0.25–1 mcg/kg/min	Vasodilation
Vasopressin	V1 agonist		0.0005–0.002 U/kg/min	Vasoconstriction

Feeding should be instituted with an age-appropriate nutritional formula as early as possible via nasogastric tube if on stable doses of vasoactive agents. If available, consultation with other clinicians can help guide further therapy, such as infectious diseases, cardiology and surgery, depending on the specific clinical scenario. If intubated, the use of low-tidal volume ventilation strategies, with permissive hypercapnia, will minimize barotrauma and lead to earlier extubation. Above all, frequent monitoring for signs of further deterioration in this postacute resuscitation period are vital to ensure optimal recovery.

## OUTCOMES

Mortality rates for pediatric shock are entirely contingent on the inciting etiology and the location of care. Pediatric septic shock in India has a mortality rate of upwards of 50%. Hypovolemic shock, often the result of dehydration due to diarrhea, has a much lower mortality rate of between 5 and 10%. The outcome for hemorrhagic shock as a result of trauma is dependent upon whether the child can

rapidly get resuscitated with transfused blood. Cardiogenic shock due to congenital heart disease has a very poor prognosis, given the poor accessibility to urgent cardiac surgery in most regions.

Markers for a bad prognosis include signs of decompensated shock such as an initial blood pH of less than 7.1, a rapid rise of lactic acid levels, and a severely abnormal mixed venous oxygen saturation that does not respond to initial resuscitation. Children with co-morbid chronic disease or malnutrition typically do worse than previously healthy children. Younger children appear to have similar survival rates as older children. Survivors of shock often have significant complications of their disease, with neurologic alterations being the major concern due to a period of hypoperfusion during the shock state.

## PREVENTION

Shock in children is almost entirely preventable. However, this requires a multi-faceted, multi-disciplinary approach across sectors, including, but not exclusive to, ensuring full vaccination compliance, early screening and diagnosis of congenital heart disease, and ensuring accessibility to primary health-care during times of mild illness and trauma prevention strategies. In the primary health-care setting, ensuring that children with acute illness are recognized and treated before signs of decompensated shock ensue will significantly reduce the burden of pediatric shock. Treating children during these 'golden hours' will result in significant improvement, and missing out on this opportunity to improve their outcomes will invariably result in more frequent and severe cases of shock. This may include referring children to higher levels of care early in their course if there is a suspicion that shock may soon develop, for further monitoring, hydration, and supportive care as needed, in as safe and expeditious a manner as possible. The greatest challenge in this regard is in recognizing the child who is soon to develop shock, a skill that is difficult to learn, and in ensuring that resources are available for an efficient transport. The use of early warning scores may assist clinicians in this regard, although further study is required before implementation.

### IN A NUTSHELL

- Shock is a syndrome where oxygen supply is inadequate for oxygen needs.
- Shock can be classified in a variety of ways:
  - Physiologically: (1) Inadequate tissue flow; (2) Inadequate blood substrate delivery; (3) Inadequate oxygen extraction.
  - Mechanistically: (1) Distributive; (2) Cardiogenic; (3) Hypovolemic.
  - By stage: (1) Compensated; (2) Decompensated; (3) Irreversible.
  - By clinical exam: (1) Warm shock; (2) Cold shock.
- Septic shock is the most common cause of pediatric shock globally, and can fall within any of the above classifications.
- Treatment is primarily geared at restoring oxygen balance by enhancing oxygen delivery primarily through supportive care, fluids and vasoactive agents.
  - Treatment can be monitored through serial clinical exams and blood gas measurements.
- For septic shock, early antibiotics are the mainstay of therapy.
- The outcomes for children with shock are variable and dependent upon the inciting cause and the access to higher levels of care.
- Shock can be prevented, or minimized, if it is recognized early in its course and appropriately acted upon.

## Chapter 8.3

# Acute Respiratory Distress Syndrome

Venkat Shankar

Acute lung injury (ALI) and acute respiratory distress syndrome (ARDS) are common causes of acute hypoxemic respiratory failure in adults and children. It was recognized as a clinical syndrome by Laennec as early as 1821 and elegantly described by Sir William Osler in 1925. Nevertheless, the term ARDS was coined by Ashbaugh in 1967 who also provided a comprehensive and definitive description of the clinical and pathological picture. The initial name adult respiratory distress syndrome was changed to acute respiratory distress syndrome in 1994 to include the children with this disorder as well. In 1994, a consensus conference [American-European Consensus Conference (AECC)] established the clinical criteria for encouraging a consistent identification and definition of this syndrome (**Table 1**). Over the past 20 years, the AECC definition has been widely used for studying ARDS across the world. Recently, a new revised definition (Berlin definition) has

been proposed to address some of the shortcomings of the original AECC definition (**Table 2**).

## EPIDEMIOLOGY

Early estimates from the National Institutes of Health suggested an annual incidence of 75 per 100,000 people in the US. The recent US and European reports of incidence of ARDS have been much lower, around 5–33 new cases/100,000 adults per year. There have been only a small number of population-based studies in children published in the past decade from around the world and they report a much lower incidence of 2.9–9.5 cases/100,000 children per year. However, the incidence is still significant when viewed from the perspective of a pediatric critical care provider and the resultant resource utilization for children with ARDS in pediatric intensive care unit (ICU) is substantial. The reported incidence of ARDS in children admitted to pediatric ICU ranges from 8.5 to 16 per 1,000 ICU admissions. The earlier reported adult mortality associated with ARDS was 40–60%. However, the more recent mortality attributable to ARDS in adults is 34–36%. The death associated with ARDS is often multifactorial and associated with multiple organ system dysfunction and is difficult to assign it to just the hypoxemic respiratory failure. In children, there is a paucity of outcome data, with the reported mortality being slightly lower than adults, in the range of 27–35%.

## ETIOLOGY

A variety of clinical conditions that can cause lung injury either directly or by a systemic inflammatory response can lead to ARDS. The common disorders causing direct lung injury are pneumonia, aspiration, inhalation, trauma and near-drowning whereas the systemic ones include sepsis, shock, pancreatitis, burns, cardiopulmonary bypass, transfusion of blood products and drug toxicity. These disorders are listed in **Table 3**. In the tropical countries, a variety of infections can cause ARDS by causing systemic inflammatory response that subsequently leads to ALI. The common ones include malaria, dengue, scrub typhus, leptospirosis and influenza.

## PATHOGENESIS AND PATHOPHYSIOLOGY

During the early phases of ARDS, there is intense inflammatory response that leads to endothelial injury and increased permeability of the alveolar-capillary interface resulting in exudation of protein-rich edema fluid in the alveolar air space.

**Table 1** American-European Consensus Conference definition of acute respiratory distress syndrome (1994)

Clinical feature	Criteria
Timing	Acute onset
Chest radiograph	Bilateral infiltrates
Oxygenation	Severe hypoxemia on oxygen therapy
Acute lung injury	$\text{PaO}_2/\text{FiO}_2$ ratio < 300
Acute respiratory distress syndrome	$\text{PaO}_2/\text{FiO}_2$ ratio < 200
Noncardiogenic origin of pulmonary edema	Pulmonary artery occlusion pressure less than 18 mm Hg or other clinical assessment of lack of elevated left atrial filling pressure

Abbreviations:  $\text{PaO}_2$ , arterial partial pressure of oxygen;  $\text{FiO}_2$ , fraction of inspired oxygen.

**Table 2** The Berlin definition of acute respiratory distress syndrome (2012)

Clinical feature	Criteria
Timing	Within 1 week of a known clinical insult or new or worsening respiratory symptoms
Chest imaging*	Bilateral opacities—not fully explained by effusions, lobar/lung collapse, or nodules
Origin of edema	Respiratory failure not fully explained by cardiac failure or fluid overload. Need objective assessment (e.g., echocardiography) to exclude hydrostatic edema if no risk factor present
Oxygenation**	
Mild	$200 \text{ mm Hg} < \text{PaO}_2/\text{FiO}_2 \leq 300 \text{ mm Hg}$ with PEEP or CPAP $\geq 5 \text{ cm H}_2\text{O}$ ***
Moderate	$100 \text{ mm Hg} < \text{PaO}_2/\text{FiO}_2 \leq 200 \text{ mm Hg}$ with PEEP $\geq 5 \text{ cm H}_2\text{O}$
Severe	$\text{PaO}_2/\text{FiO}_2 \leq 100 \text{ mm Hg}$ with PEEP $\geq 5 \text{ cm H}_2\text{O}$

\*Chest radiograph or computed tomography scan.

\*\*If altitude is higher than 1000 m, the correction factor should be calculated as follows:  $[\text{PaO}_2/\text{FiO}_2 \times (\text{barometric pressure}/760 \text{ mm Hg})]$ .

\*\*\*This may be delivered noninvasively in the mild acute respiratory distress syndrome group.

Abbreviations: CPAP, continuous positive airway pressure;  $\text{FiO}_2$ , fraction of inspired oxygen;  $\text{PaO}_2$ , partial pressure of arterial oxygen; PEEP, positive end-expiratory pressure.

**Table 3** Common clinical conditions leading to acute respiratory distress syndrome in children

Systemic cause	Direct pulmonary injury
Sepsis	Viral/bacterial pneumonia
Septic shock	Aspiration pneumonia
Hypovolemic shock	Gastric content aspiration
Pancreatitis	Hydrocarbon inhalation
Burns	Smoke inhalation
Cardiopulmonary bypass	Noxious gas inhalation
Fat embolism	Thoracic radiation
Multiple organ major trauma	Near drowning
Malaria	Fungal pneumonia
Transfusion related acute lung injury	Bronchoalveolar lavage/ surfactant washout
Multiple organ system dysfunction/ failure	Ventilator-induced lung injury
Drug toxicity	Traumatic lung contusion
Ischemia-reperfusion injury	

**Figure 1** Microscopic appearance of lung in acute respiratory distress syndrome showing extensive alveolar injury, exudation, inflammatory cells and proliferative changes  
Source: Photomicrograph by Dr Elena Puscasu.

There is an accompanying alveolar epithelial injury that results in dysfunction and loss of Type I cells as well as the cuboid type II alveolar epithelial cells. This leads to alveolar epithelial disruption, alveolar flooding, loss of gas exchange capability, loss of surfactant, potential for secondary bacterial infection and ultimately fibrosis (**Fig. 1**). The presence of fluid in the air space leads to activation of cytokines and other proinflammatory mediators, neutrophil and macrophage activation causing further inflammatory response.

Due to the alveolar air space fluid exudation and increased lung water, the pulmonary compliance is significantly reduced and it leads to poor gas exchange, mismatch between ventilation-perfusion ratio (V/Q) and hypoxemia. There are many areas of the lung that have nonexistent gas exchange leading to significant intrapulmonary shunt and severe pulmonary venous desaturation.

The desaturated pulmonary venous admixture leads to severe arterial hypoxemia, a hallmark of ARDS.

The lung is not uniformly affected, and has areas of relatively preserved alveolar units interspersed with severely atelectatic lung segments. Consequently, ARDS lung is not overall a poorly compliant lung but has differential compliance in different parts of the lung. This has led to the hypothesis that ARDS lungs are not stiff lungs but more of a *baby lung* with an overall reduced area of gas exchange available, akin to the lungs of a small baby. The resultant compliance will correlate with the degree of the normally ventilated tissue. Along with the severe arterial hypoxemia, hypercapnea is often present in ARDS due to decreased effective area for alveolar ventilation secondary to the alveolar injury and increased physiological dead space.

Secondary pulmonary hypertension is often seen in cases of ARDS. This is a result of parenchymal destruction, microvascular thrombosis, vascular spasm and compression and hypoxic pulmonary vasoconstriction.

The initial exudative phase of ARDS is often followed by a proliferative phase when new type II alveolar cells proliferate, along with fibroblasts, myofibroblasts and new matrix is deposited as there is a slow resolution of the pulmonary edema. This proliferative phase can start as early as 72 hours after the onset of ARDS and can last for 7–10 days. This phase could resolve and lead to reconstitution and repair or sometimes it could lead to progressive fibrosis phase that often leads to progressive hypoxemia, increased dead space and hypercapnea, and inability to wean from respirator and can lead to mortality.

There is an observed association between ARDS and multiple organ system failure (MOSF) that is poorly understood. The presence of MOSF is a major predictor of poor outcome.

## CLINICAL FEATURES

The syndrome is characterized by an acute severe progressive hypoxemia after an inciting event or clinical condition as listed in **Table 3**. There is dyspnea and increased work of breathing due to poor compliance and increased dead space. The auscultation could reveal diminished breath sounds and crackles, although these are not necessarily present. The chest radiographs often will reveal bilateral patchy radiodensities/infiltrates (**Fig. 2**). The CT scan reveals patchy distribution of the disease with areas of atelectasis and other areas of relatively preserved lungs (**Fig. 3**).

**Figure 2** Chest radiograph in acute respiratory distress syndrome showing bilateral infiltrates

**Figure 3** Chest CT showing uneven distribution of alveolar derecruitment with more severely affected dependent lung segments

The AECC definition for diagnosing ARDS is listed in **Table 1**. This definition has been widely used, however was not specific about the timing of an *acute onset* and was subject to unreliability due to variable application of positive end-expiratory pressure (PEEP), which was not defined. The Berlin definition (**Table 2**) defines acute onset as less than 7 days after a known clinical insult or new respiratory symptoms. It specifies a minimum amount of PEEP ( $>5$  cm H<sub>2</sub>O) as a prerequisite and further categorizes the ARDS into mild, moderate and severe based on the ratio of partial pressure of arterial oxygen to fraction of inspired oxygen ( $\text{PaO}_2/\text{FiO}_2$ ). It also improves the inter-rater reliability of radiologic findings by more specific description of the radiologic criteria. These revised definitions also removed the criterion used in AECC definition for establishing a pulmonary capillary wedge pressure below 18 cm H<sub>2</sub>O and added more clarity to improve ability to exclude cardiac causes of bilateral infiltrates. Although both compliance and physiological dead space are significantly altered in ARDS, there is no easy method of measuring these parameters in many clinical settings. Consequently, the revised definition has not included these as part of the criteria.

The pediatric cases of ARDS have similar presentation and definition as the adults. However, it is occasionally difficult in children to place an invasive arterial line for monitoring arterial  $\text{PaO}_2$ . Consequently, in children with acute hypoxemic respiratory failure that are managed without arterial lines, traditional criteria cannot be used to diagnose ARDS. Consequently, noninvasive correlates of hypoxemia have been recently established with a proposal to modify definition of ARDS for children to include noninvasive parameters as well. Peripheral capillary oxygen saturation to  $\text{FiO}_2$  ratio ( $\text{SpO}_2/\text{FiO}_2$ , substituting  $\text{SpO}_2$  for  $\text{PaO}_2$ ) and the oxygen saturation index [ $(\text{FiO}_2 \times \text{mean airway pressure})/\text{SpO}_2$ ] are being currently validated as surrogates for measuring the degree of hypoxemia and establishing their validity.

## Complications

The complications associated with ARDS can be related to the underlying clinical disorder that led to ARDS or due to the progressive hypoxemia and impaired lung mechanics. As mentioned earlier, there is a very high incidence of MOSF associated with ARDS. Acute kidney injury and renal failure are common in children with ARDS. Due to the cardiopulmonary interaction, both the pathophysiology of lung disease as well as the treatment used

(positive pressure mechanical ventilation leading to increased mean airway pressure) can cause significant cardiovascular dysfunction. The preload (decreased venous return), the afterload (increased due to pulmonary hypertension) as well as contractility (hypoxemia, coronary ischemia) are affected, often necessitating vasoactive agents to support cardiac output. The lungs can have evidence of barotrauma—air leaks like pneumothorax or pneumomediastinum or subcutaneous emphysema. There could be ventilator-induced lung injury secondary to high settings of the ventilator required. Secondary infections are often a risk due to presence of endotracheal tube, invasive vascular lines and urinary catheter. Prolonged mechanical ventilation, need for tracheostomy and chronic ventilation, muscular weakness due to disuse, critical illness myopathy or malnutrition are complications that are often seen.

## APPROACH TO DIAGNOSIS

The diagnosis of ARDS is often established based on the presence of an underlying clinical disorder and an acute progressive hypoxemic respiratory failure with radiological findings as defined in the two definitions. The essential laboratory test is the  $\text{PaO}_2$  in an arterial blood sample. This is required to calculate the  $\text{PaO}_2/\text{FiO}_2$  ratio. A plain anterior-posterior view chest radiograph is usually sufficient to establish the radiological findings. In occasional cases, a high-resolution chest CT is helpful in better delineating the extent and distribution of the parenchymal pathology. An echocardiogram may be useful in ruling out any primary cardiac disorder as the primary cause of pulmonary edema. Additional laboratory values that help with establishing diagnosis or help with management include arterial partial pressure of carbon dioxide ( $\text{PaCO}_2$ ), pH, lactate and complete blood count and serum electrolytes, renal and hepatic function tests. Blood culture, tracheal secretion culture, bronchoalveolar lavage, pleural fluid analysis and lung biopsy are other possible tests that can help with the management. Measurement of physiological dead space and pulmonary compliance can be helpful in evaluating the extent of disease and its progress. A valuable test during severe hypoxemia is the measurement of systemic central venous oxygen saturation ( $\text{ScvO}_2$ ) obtained from a central venous line placed near right atrium that can help with optimizing oxygen delivery and tailoring the therapies. Measuring tissue oxygenation in cerebral and splanchnic tissues using near infrared spectroscopy is increasingly being used to monitor adequacy of tissue oxygenation during extremely hypoxic states in ARDS to prevent organ dysfunction and permanent injury. All children with ARDS should have continuous noninvasive monitoring of systemic oxygenation ( $\text{SpO}_2$  by pulse oximeters) and ventilation (end-tidal  $\text{CO}_2$  by capnography).

## MANAGEMENT

The broad goals of management of ARDS are:

- Treatment of the underlying disorder
- Provide adequate oxygenation and ventilation without causing iatrogenic harm
- Support the multiple organs systems showing dysfunction.

Although there has been a lot of research in attempting to attenuate or modify the lung injury and its course, no specific therapy has been found till date that alters the course of the injury. The initial supportive measures include ensuring patency of the airway, clearance of secretions, and providing supplemental oxygen via nasal cannula or facemask. There has been an increasing early use of humidified high flow nasal cannula systems that can provide higher flows of 8–32 L/min in a safe manner.

## Noninvasive Ventilation

Noninvasive positive-pressure ventilation (NPPV) has been suggested for early ARDS either with a nasal prong or facemask providing continuous positive airway pressure or bilevel positive airway pressure. This is especially desirable in children who are immunosuppressed where endotracheal intubation and mechanical ventilation may pose additional risk. The NPPV can help with recruitment of alveoli, improving functional residual capacity (FRC), stabilizing the chest wall, unloading the inspiratory muscles and improving respiratory mechanics. However, NPPV often requires sedation to reduce anxiety and to maintain proper seal, which may pose a risk of respiratory depression. In addition, there is risk of aspiration of oropharyngeal secretions as well as gastric distention and emesis.

## Endotracheal Intubation and Mechanical Ventilation

This is the most effective way of optimizing oxygenation and ventilation in patients with ARDS. Over the last 15 years, the emphasis has shifted from achieving near normal blood gas values of  $\text{PaO}_2$  and  $\text{PaCO}_2$  to providing sufficient oxygenation and ventilation while ensuring lung protection and avoiding ventilator-induced lung injury. This has led to use so-called *lung protective* settings of lower  $\text{FiO}_2$ , limiting plateau pressures to less than 30 cm  $\text{H}_2\text{O}$ , low tidal volume (6–8 mL/kg). Consequently, the accepted targets often include  $\text{PaCO}_2$  in 60–80 mm Hg range, pH of 7.25 or higher and a  $\text{SpO}_2$  of 88% or greater (**Tables 4 and 5**). There is wide variation amongst various centers about the preferred mode of mechanical ventilation for ARDS, with no evidence to suggest superior outcomes of one mode over another (**Flow chart 1**).

## Open Lung Strategy

Preventing repeated opening and closing of alveolar segments is believed to be more protective for the lungs. Similarly, preventing overstretching or overdistention of the alveoli is considered to be desirable. These are often achieved by using adequate PEEP often in the range of 5–18 cm of  $\text{H}_2\text{O}$ . Some practitioners advocate for early application of high frequency oscillatory ventilation (HFOV) as an ideal lung protective ventilation by providing optimal recruitment of lungs without cyclic shear trauma due to tidal ventilation. However, there is paucity of recent pediatric literature supporting this approach. Additionally, two recent large randomized studies in adults have failed to show HFOV to improve outcomes.

## Extracorporeal Membrane Oxygenation

It has been used as a rescue therapy for supporting oxygenation and ventilation when conventional treatment has failed. Despite lack of large RCT showing clear outcome benefits, extracorporeal membrane oxygenation (ECMO) is useful for reducing the potential for ventilator-induced lung injury by minimizing the settings on conventional ventilator. Both venovenous as well as venoarterial ECMO can be utilized. Many cases of severe ARDS during the recent pandemic of H1N1 influenza were successfully managed using venovenous ECMO in adults. A modification of ECMO with lower flow rates and simpler technology called extracorporeal  $\text{CO}_2$  removal is able to effectively remove  $\text{CO}_2$ , thereby helping reduce the barotrauma or lung injury in patients with ARDS and extremely noncompliant lungs.

In many instances, despite optimizing the mechanical ventilation settings or using venovenous ECMO, one has to accept lower oxygenation (permissive hypoxemia) and higher  $\text{CO}_2$  (permissive hypercapnea) to prevent any further ventilator-

**Table 4** Permissive hypercapnea

Benefit	Risk
Right shift of oxygen dissociation curve	Increased intracranial pressure
Increased cardiac output	Pulmonary hypertension
Reduced ventilator-induced lung injury	Right ventricular dysfunction
Better lung healing potential	Arrhythmias

**Table 5** Lung protective ventilation strategy

Parameter	Recommendation
Tidal volume	6–8 mL/kg of ideal body weight
Plateau pressure	< 30 cm of $\text{H}_2\text{O}$ (water)
$\text{FiO}_2$	< 0.6
PEEP	Greater than lower inflection point, or a value that optimizes dynamic compliance
Arterial pH	> 7.20, may use sodium bicarbonate to buffer
Arterial $\text{PaO}_2$	> 50 mm Hg (with concurrent monitoring tissue oxygenation/venous saturation and lactate to ensure adequate oxygen delivery)

Abbreviations:  $\text{PaO}_2$ , arterial partial pressure of oxygen;  $\text{FiO}_2$ , fraction of inspired oxygen, PEEP, positive end-expiratory pressure.

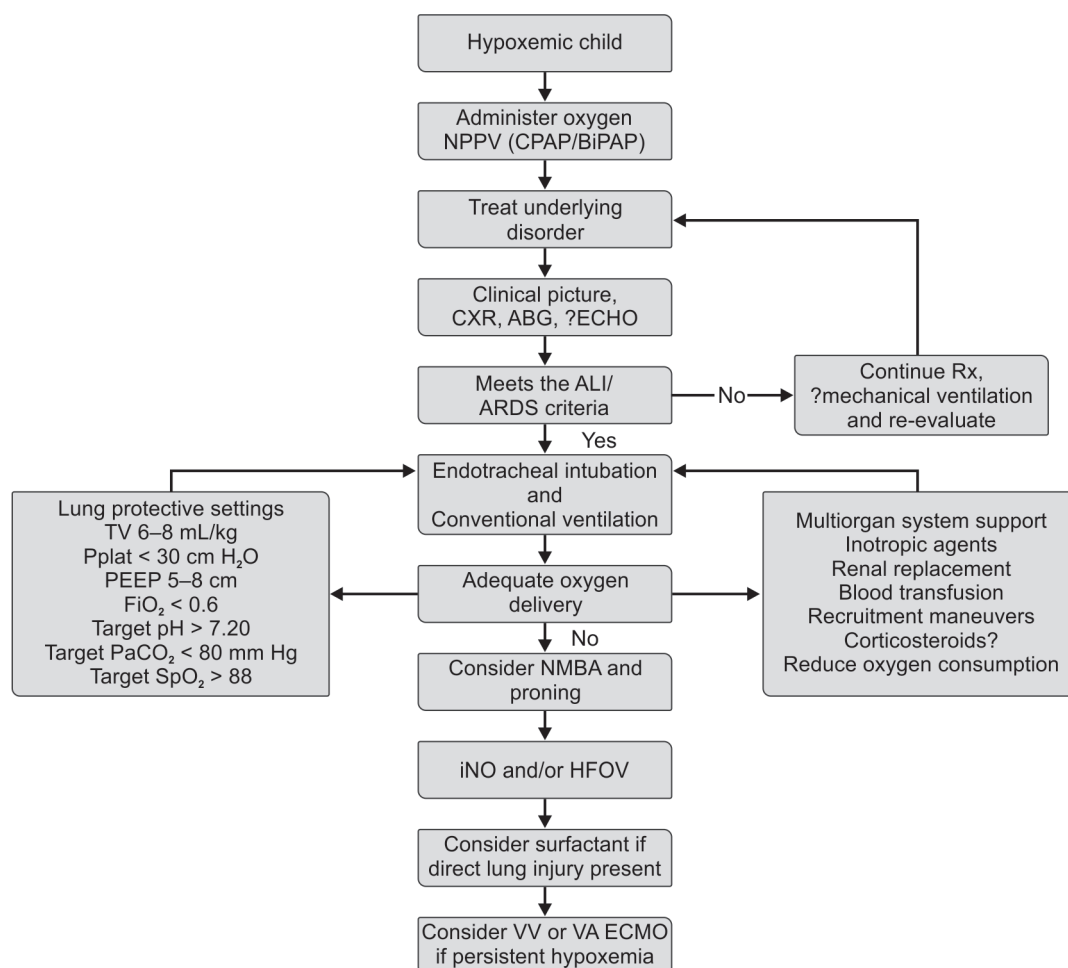

induced injury to the relatively healthy alveolar units. In these situations, it is helpful to focus on monitoring and improving oxygen delivery and reducing consumption rather than just trying to improve oxygen saturation. The oxygen delivery  $\text{DO}_2$  is determined by cardiac output as well as hemoglobin concentration in addition to oxygen saturation by the following formula:

$$\text{DO}_2 = \text{CO} \times (\text{Hb} \times 1.39 \times \text{SaO}_2 + \text{PaO}_2 \times 0.003)$$

Where CO = cardiac output, Hb = hemoglobin concentration of blood,  $\text{SaO}_2$  = oxygen saturation of arterial blood,  $\text{PaO}_2$  = partial pressure of oxygen in arterial blood. As is evident, one can help the oxygen delivery by improving cardiac output (fluid bolus, inotropic support) or hemoglobin (red cell transfusion) even in the presence of a lower  $\text{SaO}_2$ .

## Prone Positioning

It has been used as an adjunctive therapy to the ventilator management. The child is prone for at least 18 hours or more everyday. From a physiological standpoint, prone position improves the V/Q matching, and improves aeration to the dorsal portion of the lungs and helps recruit the dependent alveoli. Although prone positioning has been shown to improve oxygenation, it has not shown any improvement in outcomes of ventilator-free days or survival except in a small subgroup of adults with severe hypoxemia with  $\text{PaO}_2/\text{FiO}_2$  ratio of 100 or less. On the other hand, proning is also associated with accidental dislodgement of endotracheal tube or vascular access and pressure-related ulcers (**Table 6**). Other methods of recruitment maneuvers have been described to augment alveolar recruitment and FRC. Often they can produce immediate and dramatic improvement in oxygenation. However, routine use of these techniques has not been recommended, as there has not been any demonstrable improvement in outcomes.

**Flow chart 1** A suggested algorithm for management of acute respiratory distress syndrome in children

**Abbreviations:** NPPV, noninvasive positive-pressure ventilation; CPAP, continuous positive airway pressure; BiPAP, bilevel positive air pressure; CXR, chest X-ray; ABG, arterial blood gases; ECHO, echocardiography; ALI, acute lung injury; ARDS, acute respiratory distress syndrome; PEEP, positive end-expiratory pressure;  $\text{PaCO}_2$ , arterial partial pressure of oxygen;  $\text{FiO}_2$ , fraction of inspired oxygen; iNO, inhaled nitric oxide;  $\text{SpO}_2$ , peripheral capillary oxygen saturation; VV, venovenous; VA, venoarterial; TV, tidal volume; Pplat, plateau pressure; NMBA, neuromuscular blocking agent; ECMO, extracorporeal membrane oxygenation.

### Inhaled Nitric Oxide

Inhaled nitric oxide or other inhaled pulmonary vasodilators like aerosolized prostacyclin have been used to improve oxygenation in children with ARDS. Unfortunately, despite showing a transient improvement in oxygenation, these therapies have not conferred any survival benefits in large-scale studies.

### Corticosteroids

They have been studied extensively in the setting of adult patients with ARDS to attenuate the inflammatory and fibroproliferative response. There have been variable results between various studies and no consistent survival benefit has been observed. Consequently, the use of corticosteroids in ARDS remains controversial.

### Surfactant

Acute respiratory distress syndrome often leads to a secondary deficiency of surfactant due to destruction of type II cells and the inflammatory exudates. However, the role of exogenous

administration of surfactant in ARDS remains controversial. There has been a single small study in children that showed improved outcomes in ARDS associated with direct lung injury.

### Muscle Relaxants

Prolonged use of neuromuscular blocking agents can lead to muscular atrophy, myopathy and inability to wean of the ventilator. However, recent experience indicates that judicious use of muscle relaxants in early phase of ARDS in adults improves survival outcomes and ventilator-free days. No pediatric experience is available currently, but use of muscle relaxants to promote improved ventilator-patient synchrony, optimize oxygen consumption and delivery has been an acceptable therapy.

### Fluids

Total body fluid overload seems to be associated with worsening pulmonary compliance, hypoxemia and unfavorable outcomes in adults and children. Consequently, fluid restriction or early

**Table 6** Adjunctive therapy for acute respiratory distress syndrome

Therapy	Rationale	Current evidence/comments
Inhaled nitric oxide, aerosolized prostacyclin	Pulmonary vasodilator, improved V/Q matching and oxygenation	Despite significant improvement in oxygenation, failed to show improved clinical outcomes
Prone positioning	Improved aeration of dorsal lung segments, improved V/Q matching, better recruitment of alveoli	Definite improvement in oxygenation seen. Survival benefits seen only in severe ( $\text{PaO}_2/\text{FiO}_2 < 100$ ) hypoxemia group. Risk of endotracheal tube dislodgment, pressure ulcers
Recruitment maneuvers (RM)	Alveolar derecruitment is common with low tidal volume ventilation, RM can improve V/Q mismatch	Transient increase in oxygenation seen. No change in barotrauma or mortality. Use of concomitant high PEEP to maintain recruitment
Surfactant administration	Loss of surfactant due to alveolar cell injury, inflammatory exudate causes atelectasis	Suggestion of modestly improved outcomes in ARDS secondary to direct lung injury. Expensive and impractical
Neuromuscular blocking agents	Patient-ventilator dyssynchrony can cause worse oxygenation, lung injury	Recent evidence showing survival benefits if used early in adults. Risks of prolonged muscle weakness and ventilator dependency
Corticosteroids	ARDS is due to inflammatory process and steroids can modulate inflammatory response	Variable results from various adult ARDS studies. No consistent outcome benefits observed. Remains controversial
Fluid restriction	Total body fluid overload associated with poor compliance, oxygenation and poor outcomes	Fluid restriction after initial shock resuscitation or diuresis often shows improved oxygenation. No consistent survival benefits shown
Continuous venovenous hemofiltration (CVVH)	Total body fluid overload associated with poor compliance, oxygenation and poor outcomes. Possible clearing of cytokines	Early aggressive CVVH shown in children with stem cell transplant to improve outcome in a small case series. No conclusive evidence about outcome benefits despite improved oxygenation
Early enteral nutrition, fatty acid supplements, antioxidants	Decreased muscle loss, better diaphragm strength, attenuated inflammatory response	Conflicting results about benefits of early enteral feedings on outcomes, supplementing fatty acids not conclusively shown to change outcomes

*Abbreviations:* PEEP, positive end-expiratory pressure; ARDS, acute respiratory distress syndrome; V/Q, ventilation-perfusion ratio;  $\text{PaO}_2$ , arterial partial pressure of oxygen;  $\text{FiO}_2$ , fraction of inspired oxygen.

aggressive diuresis/continuous hemofiltration in cases of renal failure is desirable.

### Nutrition

Ensuring adequate nutrition despite fluid restriction is essential for healing of lungs and ability to wean of the mechanical ventilator. Enteral nutrition is possible in most children, and chances of the success of enteral feeds are higher with transpyloric feeding.

### Organ Support

As mentioned earlier, most children with ARDS do not die due to severe hypoxemia but rather due to MOSF. Providing cardiac, renal, hepatic, hematologic and neurologic organ system support is an essential component of the management strategy and these specific organ support therapies are discussed elsewhere in this book.

### PROGNOSTIC FACTORS

Unlike adults, severity of hypoxemia (lower  $\text{PaO}_2/\text{FiO}_2$  ratios) at presentation has been shown to be a predictor of poor outcome and mortality in children. Presence of multiple organ system failure, pre-existing immunocompromised state and a history of stem cell transplantation are also predictors of poor outcome. Overall, the reported mortality of children with ARDS is lower than those of adults as described earlier.

### IN A NUTSHELL

1. ARDS and ALI are a significant cause of morbidity and mortality in children.
2. The diagnosis is established using an internationally accepted standard clinical, laboratory and radiologic criteria.
3. A large number of common systemic or lung-related clinical conditions could lead to ARDS.
4. The cornerstone of management is mechanical ventilation to provide adequate oxygenation and ventilation without causing iatrogenic lung injury.
5. The mechanical ventilation should be lung protective, using low tidal volume (6–8 mL/kg), limited plateau pressure (< 30 cm of  $\text{H}_2\text{O}$ ) and sufficient PEEP to avoid atelectasis and optimal recruitment to keep the lungs open.
6. Permissive hypercapnea is usually required, and lower oxygenation saturations are acceptable if there is evidence of adequate oxygen delivery.
7. Multiple organ failure is commonly associated with ARDS and is a major determinant of the outcome. Multiple organ system support is often needed in the ICU.
8. Multiple therapies including inhaled nitric oxide, prone position, corticosteroids, surfactant, fluid restriction and ECMO are still being evaluated for their beneficial effects on clinical outcomes in ARDS.

## Chapter 8.4

# Respiratory Failure

Lokesh Guglani

Respiratory failure is the inability of the respiratory system to maintain adequate oxygenation of the blood and body tissues, or the loss of its ability to ventilate adequately. In this condition, the respiratory system is unable to meet the metabolic demands of the body for the purpose of oxygenation and/or elimination of carbon dioxide. It can occur as an acute process due to several respiratory and nonrespiratory disorders, or become chronic in those with underlying chronic lung, heart or neuromuscular disorders. Severe acute respiratory failure is associated with an imminent risk of cardiac arrest, while those with chronic respiratory failure can develop complications such as pulmonary hypertension and cor pulmonale, or remain at risk for the development of acute-on-chronic respiratory failure due to an intercurrent illness. It is important for pediatricians to recognize early signs and symptoms of respiratory failure in infants and children to provide timely and appropriate treatment for their patients.

## EPIDEMIOLOGY

Acute respiratory infection (ARI) remains the leading cause of acute respiratory failure in children. Bacterial pneumonias account for the majority of cases, and are associated with 1.1 million deaths per year in children less than 5 years of age, accounting for one-fifth of the mortality in this age group. Children with severe malnutrition, pre-existing illnesses (HIV infection or measles), and other environmental risk factors (parental smoking, exposure to biomass fuels) have the greatest risk. Chronic lung infections such as tuberculosis and circulatory shock (due to various causes) also account for significant morbidity in the pediatric age group. The spectrum of disorders associated with respiratory failure in the neonatal age group is different from that seen in older children and has been covered in Section 17.

## ETIOLOGY

The etiology of respiratory failure in children can be conceptually divided into broad categories involving the lungs, the muscles involved in respiration (the so-called *pump* that drives respiration), the neural networks involved in regulation of breathing, cardiac disorders and systemic illnesses that affect the respiratory system as well. **Box 1** highlights these categories and the specific conditions that cause respiratory failure in children.

## PATHOGENESIS

Acute respiratory failure has been traditionally categorized based on the presence of hypoxemia and/or hypercapnia into two broad categories. *Type I respiratory failure* occurs due to any condition that leads to hypoxemia ( $\text{PaO}_2 < 50$  mm Hg on room air). *Type II respiratory failure* is characterized by elevated  $\text{pCO}_2$  levels more than 50 mm Hg (unless there is chronic respiratory failure when the level could be higher) that develops in response to hypoventilation due to a number of etiologies listed under *pump failure*. It is important to remember that as alveolar  $\text{pCO}_2$  and thus arterial  $\text{pCO}_2$  rise, the  $\text{PaO}_2$  will also fall. Hence, Type II respiratory failure will have both hypercarbia and hypoxemia.

The lung can be imagined in a simplified model of gas exchange to contain alveoli that show matching of ventilation with perfusion to maintain oxygenation and facilitate removal of carbon dioxide

(**Fig. 1**). Any disease process that affects this balance is likely to lead to hypoxemia and this is highlighted in the scenarios presented in **Figure 1**. The middle segment in **Figure 1** is the normal state of gas exchange where alveolar blood flow is perfectly matched with alveolar ventilation leading to a V/Q ratio of 1. However, in situations where airflow obstruction limits the alveolar ventilation (left panel in **Figure 1**), the lung tries to overcome imbalances in ventilation to different alveolar units by reducing the perfusion of under-ventilated alveolar units (through hypoxic pulmonary vasoconstriction) to maintain the overall V/Q ratio of the lung. With increasing degree of airways obstruction (such as in severe acute exacerbation of asthma), these compensatory mechanisms can be overcome and overt hypoxemia can develop due to decline in alveolar ventilation that is out of proportion to the changes in perfusion (low V/Q ratio). The other extreme can be seen in situations where pulmonary perfusion alone is affected while ventilation remains intact. In this case, the relatively well ventilated but poorly perfused alveolar units constitute an alveolar dead space where no effective ventilation is occurring and the V/Q in these units is more than 1. With complete obstruction of pulmonary blood flow in a large vessel (for example, due to pulmonary embolism), the V/Q ratio can approach infinity and lead to significant hypoxemia and decompensation. At any given time, the V/Q ratio of all the alveolar units put together in the normal lung is maintained as close to 1 as possible. Depending on the severity of the disease processes, number of alveolar units involved, and presence of pre-existing lung disease, the functional impact on oxygenation and ventilation can vary from no obvious symptoms to severely symptomatic hypoxemia and/or hypercarbia.

It is, therefore, very useful to understand the basic pathophysiology of hypoxemia in patients with respiratory failure. All of the conditions listed in **Box 1**, from a mechanistic standpoint, can be categorized under one of the following four main causes of hypoxemia (ignoring high altitude, which also causes hypoxemia, for the sake of simplicity). Measurement of alveolar-arterial  $\text{PaO}_2$  difference (also called A-a gradient) can help to diagnose the likely cause of hypoxemia (**Table 1**). Normally the arterial  $\text{pO}_2$  is slightly lower than alveolar  $\text{pO}_2$  due to normal anatomic shunt (bronchial and thebesian veins), and some degree of V/Q mismatch and diffusion limitation in the normal lung. The normal value for the A-a (Alveolar-arterial) gradient ranges between 5 and 10 mm Hg and it increases with age. It is calculated with the following equation:

$$\text{A-a gradient} = [\text{FiO}_2 \times (\text{P}_B - 47) - \text{PaCO}_2/\text{R}] - \text{PaO}_2$$

An increase in the A-a gradient can occur due to increased right to left shunt, increased V/Q mismatch, impaired diffusion, higher inspired partial pressure of oxygen, decreased mixed venous pressure of oxygen or due to a shift of the oxyhemoglobin dissociation curve.

Ventilation perfusion mismatch remains the most common cause of hypoxemia in the pediatric age group. Diffusion block refers to processes that impair gas exchange at the alveolar membrane due to presence of fluid (pulmonary edema), inflammatory infiltrate (pneumonia), surfactant dysfunction [neonatal respiratory distress syndrome (RDS)], etc. Hypoventilation encompasses all the conditions listed under pump failure (or neuromuscular weakness) causing respiratory muscle dysfunction. In specific congenital heart defects or pulmonary arteriovenous malformations, significant right to left shunting can cause hypoxemia and respiratory failure as well.

## CLINICAL FEATURES

The evaluation of the child with respiratory distress involves determination of the severity and its underlying cause. The presence of tachypnea and retractions suggests respiratory

**Figure 1** Ventilation-perfusion relationships in the lung

### BOX 1 Etiology of respiratory failure in children

#### Related to the Lungs or Airways

##### Infections

- Bacterial pneumonia
- Viral bronchiolitis
- Pulmonary tuberculosis
- Croup
- Bacterial tracheitis

##### Inflammatory disorders

- Involving the airways: Severe acute asthma
- Bronchiolitis obliterans (postinfectious)
- Involving the lung parenchyma: Acute respiratory distress syndrome
- Pulmonary edema
- Meconium aspiration syndrome

##### Airway disorders

- Subglottic or tracheal stenosis
- Extrinsic airway compression (vascular ring, enlarged lymph nodes, peritonsillar/retropharyngeal abscess)
- Vocal cord paralysis (bilateral)
- Airway foreign body

##### Air leak syndromes

- Tension pneumothorax
- Pneumomediastinum

##### Vascular disorders

- Primary pulmonary hypertension
- Persistent pulmonary hypertension (PPHN)
- Pulmonary embolism

##### Disorders of surfactant secretion and metabolism

- Neonatal respiratory distress syndrome
- Congenital disorders of surfactant protein metabolism

##### Disorders of lung development

- Chronic lung disease of prematurity (bronchopulmonary dysplasia)
- Pulmonary agenesis or hypoplasia
- Other rare lung malformations: Alveolar capillary dysplasia

##### Other lung disorders

- Pulmonary contusion
- Smoke inhalation injury

- Carbon monoxide poisoning
- Submersion injury and drowning

#### Related to Pump Failure

##### Muscular weakness

- Duchenne muscular dystrophy
- Spinal muscular atrophy

##### Demyelinating disorders

Guillain Barré Syndrome

##### Chest wall disorders

- Severe scoliosis
- Asphyxiating thoracic dystrophy (Jeune's syndrome)
- Flail chest

##### Disorders of neuromuscular junction

Myasthenia gravis

#### Related to Central Nervous System

##### Infections

- Bacterial meningitis, viral encephalitis
- Neurotuberculosis

##### Trauma

- Closed head injury
- Intracranial hemorrhage

##### Pharmacologic agents

Benzodiazepines, barbiturates, narcotics

##### Brainstem disorders

- Extrinsic compression from hemorrhage, tumors, or any other space occupying lesions
- Malformations involving the brainstem

##### Congenital central hypoventilation syndrome (Ondine's curse)

#### Cardiac disorders

- Congestive heart failure
- Congenital heart disease

#### Secondary to Systemic Disorders

##### Sepsis and shock

- Dengue shock syndrome
- Gram-negative sepsis
- Hemorrhagic shock

##### Anaphylaxis and angioedema

Hematologic disorders Acute chest syndrome in sickle cell disease.

distress, and respiratory rate cut-offs for different age groups (as shown in **Box 2**) can objectively identify distress. The appearance of the child including their muscle tone and posture; interaction with the environment (consolability in young infants); nature of their speech or cry; and the use of accessory muscles of respiration (sternocleidomastoid, scalene muscles), with or without head

bobbing or nasal flaring, can help assess the severity by inspection alone. Listening for audible stridor, wheezing, grunting, snoring or muffled speech can further help assess the underlying cause. Auscultation to assess for air entry and presence of adventitious breath sounds (crackles or rales, wheezes, bronchial breath sounds, etc.) can help narrow the differential diagnoses. For children who

**Table 1** Main causes of hypoxemia and the associated changes in  $p\text{CO}_2$ ,  $p\text{O}_2$  and alveolar arterial  $p\text{O}_2$  gradient

Causes of hypoxemia	Arterial $p\text{CO}_2$	Arterial $p\text{O}_2$	Alveolar-arterial $p\text{O}_2$ difference	
			In Room Air	With 100% $\text{O}_2$
Ventilation-perfusion mismatch	Normal, increased or decreased	Decreased	Increased	Normal
Diffusion block	Normal or decreased	Normal at rest, decreased with activity	Normal at rest, Increased during activity	Normal
Hypoventilation	Increased	Decreased	Normal	Normal
Right to left shunting	Normal or decreased	Decreased	Increased	Increased

**BOX 2 Clinical signs of respiratory distress in children**

- Tachypnea: Age-specific cut-offs for respiratory rates in children (breaths/min)
  - Age 0–2 months: > 60 per min
  - Age 2–12 months: > 50 per min
  - Age 1–5 years: > 40 per min
  - Age > 5 years: > 20 per min
- Grunting
- Nasal flaring
- Dyspnea
- Retractions (suprasternal, intercostal or subcostal)
- Cyanosis
- Altered mental status
- Apnea.

may be tiring from the effort of breathing, the slowing of their respiratory rate or the presence of gasping or agonal breaths may signify overt respiratory failure that requires emergent intervention to protect the airway and maintain ventilation.

Monitoring of vital signs (temperature, heart rate, respiratory rate and blood pressure), oxyhemoglobin saturation by pulse oximetry and perfusion (capillary refill time) should be repeated at frequent intervals while the assessment is being continued. Further investigations for assessment of the cause of respiratory failure can be done on the basis of the clinical syndrome at presentation and presence of any underlying chronic (lung or heart) disorders.

**Scoring system** Several clinical scoring systems have been devised for the objective assessment of respiratory distress in infants and children. These scoring systems are especially helpful in serial assessment of the same patient over time as the score can yield data for determining the trends and overall response to therapy for each patient. Some scoring systems have been developed for specific age groups (such as Silverman-Anderson score or Downe's scoring system for neonates) or for specific disorders (such as Westley croup score). These have been used as outcome measures in randomized controlled clinical trials for assessing response to specific therapies, but their usefulness may be limited by interobserver variability in scoring.

Additional findings related to chronic respiratory disorders, such as digital clubbing, presence of polycythemia or poor nutritional status can provide additional clues.

## DIFFERENTIAL DIAGNOSES

Because tachypnea and respiratory distress may occur from several nonrespiratory conditions as well, it is important to consider them in the differential diagnosis of respiratory failure. In some situations, such as cardiac failure or circulatory shock, respiratory failure can develop secondarily due to inadequate tissue perfusion causing metabolic acidosis, which can lead to tachypnea and hyperventilation. Other conditions that cause significant metabolic acidosis, such as diabetic ketoacidosis or

inborn errors of metabolism (organic acidemias), may present with severe tachypnea as well and can be easily mistaken for a primary respiratory process. On the basis of specific investigations, such as radiographs, arterial blood gases, laboratory studies, etc., the underlying diagnosis can be fully established.

## APPROACH TO DIAGNOSIS

Rapid assessment of infants and children presenting with respiratory distress is very important for timely initiation of therapy and to promptly detect those that are critically ill and need immediate intervention. The Pediatric Assessment Triangle (PAT) (refer to chapter 7.1) is a model of assessment that can be applied in all settings (rural or urban, in-hospital or out-of-hospital) and is useful for children of all ages with all levels of illness severity. It also helps to identify the key physiologic impairments that need to be addressed. This provides a rapid assessment of the child's cardiopulmonary status without disturbing the child or needing any sophisticated equipment. In the hospital setting, the PAT assessment can be followed by primary and secondary surveys to further refine the information collected initially.

For children with acute respiratory compromise, the following clinical syndromes should be recognized in the emergency room:

- Acute upper airway obstruction—Foreign body, croup, epiglottitis
- Impending respiratory arrest—tension pneumothorax, cardiac tamponade, flail chest, hemorrhage, CNS injury
- Trauma—pneumothorax, hemothorax, pulmonary contusion, CNS injury
- Nontraumatic lower respiratory tract illnesses
  - Wheezing and/or crackles with fever—pneumonia, bronchiolitis, asthma with viral illness, myocarditis
  - Wheezing and/or crackles without fever—Atypical pneumonia, bronchiolitis, asthma, anaphylaxis, atelectasis, pulmonary edema, heart failure, foreign body, intrathoracic mass, exacerbation of chronic lung disease.
  - Tachypnea with fever—Pneumonia, sepsis, pulmonary embolism, encephalitis
  - Tachypnea without fever—Atypical pneumonia, inhalation of toxins, pulmonary masses, pneumothorax, pulmonary embolism, cardiac or metabolic disorders.
- Other systemic illnesses—Malaria, dengue fever/shock syndrome, neuromuscular disorders, etc.

Besides history, examination and pulse oximetry data, further information can be obtained from chest radiograph, laboratory tests to assess for infections, and blood gases (capillary or arterial, if feasible). For those with trauma, further primary and secondary assessments should be performed to evaluate for other sites of injuries. For patients with impending or overt signs of respiratory failure, the first priority should be to secure their airway and then continue to evaluate them for underlying cause on an ongoing basis.

## BLOOD GASES FOR ASSESSMENT OF GAS EXCHANGE

Measurement of partial pressures of gases such as oxygen and carbon dioxide, as well as estimation of pH and bicarbonate levels can be an essential step in the assessment of respiratory failure (**Table 2**). The respiratory centers in the brainstem regulate breathing by a negative feedback system via the partial pressures of CO<sub>2</sub> in the blood and cerebrospinal fluid. This allows for breath-to-breath changes in tidal volume and breathing frequency to maintain PaCO<sub>2</sub> within the normal range. Any short-term changes in alveolar ventilation that increase partial pressures of CO<sub>2</sub> in the alveolar space has an effect on the PaCO<sub>2</sub> and the pH, causing acute respiratory acidosis. There are buffers (bicarbonate, phosphate and proteins) that try to maintain the pH as close to normal as possible. In children with chronic lung disorders, the build up of carbon dioxide can occur slowly as their lung disease progresses, resulting in chronic respiratory acidosis.

### Blood Gas Classification and Interpretation (Also see Chapters 5.3 and 5.4)

The use of a systematic approach for blood gas classification ensures reproducible results and can help avoid mislabeling of the underlying primary acid base disturbances. The main components include assessment of acid-base status by evaluating the pH as the first step to define acidosis or alkalosis. This is followed by identification of the primary problem with the help of PaCO<sub>2</sub> (for the respiratory component); and then the [HCO<sub>3</sub>]<sup>-</sup> and base excess (for the metabolic component). Finally, assessing the degree of compensation for the primary disturbance acid-base disturbance completes the interpretation.

Once the pH has been classified (normal, acidosis or alkalosis), the next step is to assess for respiratory abnormality by evaluating the PaCO<sub>2</sub>, which generally has an inverse relationship with the pH. All the conditions that alter the PaCO<sub>2</sub> levels in blood are considered to be respiratory disturbances. Metabolic disturbances on the other hand, are defined by exclusion of any respiratory related acid-base disturbances. So when the PaCO<sub>2</sub> is high, the pH will be low due to accumulation of carbonic acid and this constitutes respiratory acidosis. If extent of drop in pH is greater than what would be expected for the elevation of pCO<sub>2</sub> above 40 mm Hg, then there is a mixed acid-base disturbance. However, this may be different in the setting of chronic respiratory acidosis where the extent of drop in pH may be much lower than seen in conditions associated with acute respiratory acidosis.

The third step involves the assessment of the compensatory response, which can be either complete or incomplete. This is based on the extent of change in the opposing (respiratory/metabolic) parameter for each primary acid-base disturbance. If there is respiratory acidosis, then besides a high PaCO<sub>2</sub> and low pH, there will be an accompanying increase in [HCO<sub>3</sub>]<sup>-</sup> level to compensate for this drop in pH and adjust it towards normal. If the pH is restored to the normal range, then full compensation exists but for cases where pH remains below normal, then the

compensation is partial. A stepwise approach for interpreting the arterial blood gas results is shown in **Flow chart 1**.

The renal compensatory mechanisms are generally slower than respiratory compensation for metabolic problems and may take up to 3–6 days. The kidneys compensate for respiratory acidosis and metabolic acidosis of nonrenal origin by excreting fixed acids and retaining the filtered bicarbonate. For respiratory alkalosis or metabolic alkalosis of nonrenal origin, the kidneys compensate by decreasing the hydrogen ion excretion and reducing the retention of filtered bicarbonate.

In patients with chronic respiratory failure, the control of ventilation tends to shift from the respiratory center in the brainstem to the peripheral chemoreceptors located in the carotid and aortic bodies. As the arterial pCO<sub>2</sub> rises, the central respiratory center becomes less sensitive to the rising PaCO<sub>2</sub> level acting as a stimulus for inducing hyperventilation. In fact, ventilation is driven in this situation by the hypoxemia that stimulates the peripheral chemoreceptors. The initiation of supplemental oxygen in someone with hypoxemia and hypercarbia (for example, a patient with Duchenne muscular dystrophy who presents with respiratory distress) will abolish the hypoxic drive for maintaining ventilation and may lead to worsening CO<sub>2</sub> narcosis. This is because supplemental oxygen will correct this patient's hypoxemia, but will not address the hypoventilation that caused the raised PaCO<sub>2</sub> levels in this patient in the first place.

The compensatory changes that take place in the setting of chronic respiratory acidosis and alkalosis are different from those occurring in the setting of acute respiratory acidosis or alkalosis (as shown in **Table 3**). Besides the increase in plasma bicarbonate, the renal response also includes an increase in chloride excretion, causing hyponatremia. This loss of chloride balances the increase in plasma bicarbonate levels, thereby maintaining a normal plasma anion gap.

### Other Tests

Besides changes in blood gas values, patients with chronic respiratory failure can also develop polycythemia (due to chronic hypoxic stimulus) and in extreme cases, right ventricular hypertrophy with pulmonary hypertension (cor pulmonale). This can significantly affect their effort tolerance, which can be objectively measured and tracked with a six-minute walk test. These cases may also be further evaluated by electrocardiogram and echocardiography for the assessment of cardiac function. Assessment of pulmonary function by spirometry can be performed in children older than 6 years of age to monitor progression of chronic lung disease and to assess for improvement in response to therapies.

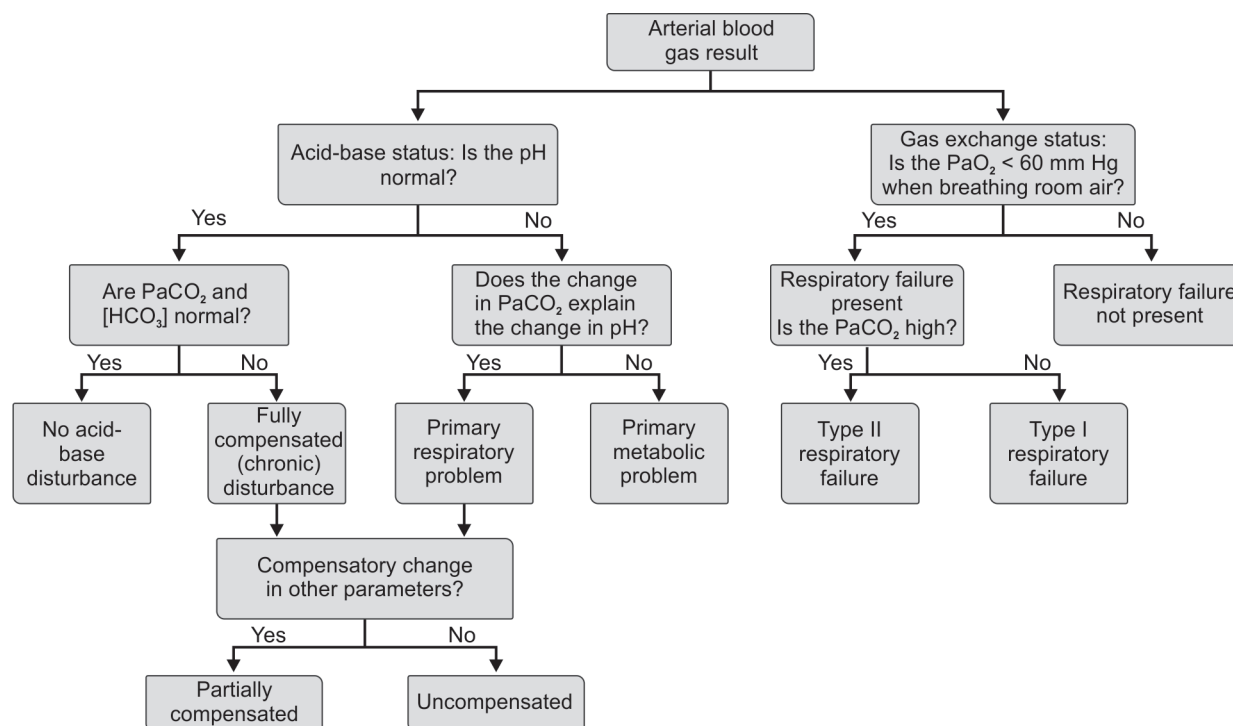

## MANAGEMENT

Management of acute respiratory failure in children generally requires treatment of the underlying cause and support of ventilatory function to maintain adequate oxygenation and tissue perfusion. Please refer to Chapter 7 regarding airway management, rapid sequence intubation and resuscitation. The correction of hypoxemia with supplemental oxygen can be the

**Table 2** Arterial blood gas values: Normal ranges and values from patients with respiratory failure

Arterial blood gas parameters	Normal values	Acute respiratory failure	Chronic respiratory failure	Acute on chronic respiratory failure
pH	7.35–7.45	7.26	7.32	7.28
PaCO <sub>2</sub>	35–45 mm Hg	60 mm Hg	60 mm Hg	70 mm Hg
PaO <sub>2</sub>	80–100 mm Hg	50 mm Hg	50 mm Hg	50 mm Hg
[HCO <sub>3</sub> ] <sup>-</sup>	24 ± 2 mEq/L	26 mEq/L	30 mEq/L	35 mEq/L
[Base excess]	0 ± 2 mEq/L	+2 mEq/L	+6 mEq/L	+10 mEq/L

**Flow chart 1** Blood gas classification and interpretation**Table 3** Changes in blood gas parameters in acute and chronic respiratory failure

	pH Change	HCO <sub>3</sub> Change
Acute respiratory acidosis	Each 10 mm pCO <sub>2</sub> Δ → pH Δ by 0.08	↑ HCO <sub>3</sub> by 1 mEq/L → each 10 mm ↑ in pCO <sub>2</sub>
Chronic respiratory acidosis	Each 10 mm pCO <sub>2</sub> Δ → pH Δ by 0.03	↑ HCO <sub>3</sub> by 3.5 mEq/L → each 10 mm ↑ in pCO <sub>2</sub>
Acute respiratory alkalosis	Each 10 mm pCO <sub>2</sub> Δ → pH Δ by 0.08	↑ HCO <sub>3</sub> by 2 mEq/L → each 10 mm ↓ in pCO <sub>2</sub>
Chronic respiratory alkalosis	Each 10 mm pCO <sub>2</sub> Δ → pH Δ by 0.17	↓ HCO <sub>3</sub> by 5 mEq/L → each 10 mm ↓ in pCO <sub>2</sub>

first step in most patients, but those with significant hypercarbia or respiratory acidosis may also require assisted ventilation. Continuous monitoring of oxyhemoglobin saturations with a pulse oximeter and/or periodic assessment of gas exchange with blood gases (when available) can help in determining the level of support needed for each individual patient according to their needs.

## Oxygen Therapy

**Nasal prongs** These deliver low-flow (1–2 L/min), low-concentration (30–35%) oxygen with two prongs that are inserted in the anterior nares and held by adhesive tape. These can be used with oxygen tanks in a clinic or walled supply in the hospital setting for patients that need lower level of support for maintaining adequate oxygenation.

**Face mask** Simple re-breathing type of face masks deliver about 30–60% concentration at flow rates of 6–10 L/min, since they have holes for the exit of exhaled air that also allow mixing with room air. They should be of adequate size, extending from the bridge of the nose to the tip of the chin, with a snug fit and put no pressure on the eyes. The nonbreathing types of facemasks have an oxygen reservoir attached to them, which allows patients to get pure oxygen held in the reservoir and minimizes mixing with room air. This helps to deliver a higher concentration of oxygen, up to 95–100% with flow rates of 10–12 L/min.

**Others** Other modalities for oxygen administration include oxygen hoods, which are used for neonates and young infants and can deliver up to 30% oxygen concentration without need for humidification; blow by oxygen for those who do not tolerate facemasks or nasal prongs, by holding the tubing close to the nose to deliver free-flow oxygen with variable concentration that cannot be regulated; oxygen tents in patients with croup (to minimize agitation); or via nasopharyngeal catheters.

## Noninvasive Positive Pressure Ventilation (NIPPV)

For patients that have significant hypercarbia and/or hypoxemia that may not respond to oxygen therapy alone, positive pressure support can be provided with less invasive modalities such as continuous positive airway pressure (CPAP) or bilevel positive airway pressure (BiPAP). This may be considered prior to the use of traditional invasive ventilatory support and can help avoid intubation and its related complications in several acute reversible as well as chronic conditions with acute decompensation. In general, noninvasive ventilation devices have evolved from use of negative pressure ventilators in patients with poliomyelitis in early 20th century to its current use for both short-term and long-term support in hospital as well as home settings. The decision to initiate NIPPV in patients with impending respiratory failure, those with an acute reversible illness or those with a chronic underlying disorder with acute decompensation, can be made

when certain criteria (**Box 3**) are met and no contraindications for NIPPV (**Box 4**) exist. The lack of skilled personnel/resources to intubate and provide ICU level care or use during transport to a higher level medical facility may be additional indications for the use of NIPPV. For patients with *pump failure* (neuromuscular weakness causing hypoventilation and chronic respiratory failure), the use of NIPPV at night time allows them to rest their fatigued respiratory muscles, improves their lung and chest wall mechanics by reducing microatelectasis and increasing chest wall excursion, and also helps to reset their central chemoreceptor sensitivity to the chronically elevated  $p\text{CO}_2$ s.

#### BOX 3 Indications for initiation of noninvasive positive pressure ventilation

Symptoms of hypoventilation and impending respiratory failure  
Underlying disorders  
Reversible acute conditions—pneumonia, acute asthma exacerbation, etc.  
Chronic respiratory disorders (associated with chronic respiratory failure)  
Neuromuscular disorders  
Upper airway obstruction  
Severe tracheobronchomalacia  
Patients with progressive physiologic impairment  
Nocturnal hypercapnia  
Vital capacity < 15 mL/kg  
Inspiratory force < 20 cm  $\text{H}_2\text{O}$   
Poor cough or secretion clearance with/without atelectasis.

A wide variety of oronasal interfaces (nasal prongs, nasal masks, oronasal masks, total face mask), circuits (single limb or double limb for inhalation and exhalation) and devices with a variety of modes are now available. CPAP is the preferred modality in patients with upper airway obstruction or tracheobronchomalacia or significant atelectasis as it helps to stent open their airways with the continuous positive pressure and maintains adequate airflow. However, BiPAP may be preferable in patients with significant hypoventilation where the higher inspiratory positive airway pressure (IPAP) ensures adequate lung expansion and air entry, and the subsequent lower expiratory positive airway pressure (EPAP) ensures adequate exhalation at a lower pressure. There are 3 different modes that are commonly used with BiPAP, which include:

**Spontaneous (S)** Where the patient's own inspiratory effort triggers the device and cycles it to EPAP.

**Timed (T)** The cycling between IPAP and EPAP is timed by the machine based on the rate of breaths/min set up on the machine.

**Spontaneous/Timed (S/T)** Similar to the spontaneous mode, the device is triggered by the patient's inspiratory effort. However, there is a back-up rate that is set to ensure that if the patient does not take enough spontaneous breaths/min, then the machine provides the minimum back up rate that has been set.

#### BOX 4 Contraindications for use of noninvasive positive pressure ventilation

Unstable airway/unable to protect airway  
Hemodynamically unstable patient  
Uncooperative, agitated patient  
Respiratory arrest, coma or obtundation due to  $\text{CO}_2$  narcosis  
Need for controlled ventilation  
Acute abdominal pathology or recent esophageal surgery  
Facial injury/trauma/burns/anomalies interfering with mask fitting.

**Complications** from NIPPV include facial skin breakdown or necrosis due to repeated pressure (especially on bridge of nose), gastric insufflation (especially in patients with esophageal reflux),

sinus problems, drying and thickening of oral secretions, and eye irritation from airflow leaks from mask. Barotrauma from NIPPV is less likely as the peak pressures usually never go beyond 25 cm  $\text{H}_2\text{O}$  and over distension generally activates the Hering-Breuer inflation reflex. Aspiration from vomiting while wearing a pressurized facemask can be avoided with careful selection of patients for NIPPV (avoiding use in patients with abdominal disorders and those who are obtunded or unable to protect their airways).

### Positive Pressure Ventilation

A majority of patients with respiratory failure will require positive pressure ventilation, especially if they are not suitable candidates for or have failed noninvasive ventilatory support. For delivery of positive pressure support, most patients require endotracheal intubation but in those with chronic respiratory failure, placement of a tracheostomy tube may be necessary to provide a secure, longer-term access to the airway. There are numerous ventilator devices, modes and approaches and these are discussed in detail in Chapter 8.5.

### Prone Positioning

In addition to the use of positive pressure ventilation, several adjunctive strategies, such as prone positioning have been used in patients with acute respiratory distress syndrome (ARDS) in the ICU setting. Because ARDS can have a nonhomogenous distribution and there is a gravity-dependent gradient of opacities evident on imaging, prone positioning allows for better aeration and perfusion of the larger, more posterior portions of the lungs, thereby maintaining ventilation/perfusion matching.

### Inhaled Nitric Oxide

Use of inhaled nitric oxide (iNO) is another adjunctive therapy that is helpful in patients with ARDS who have pulmonary hypertension, as it helps to reduce pulmonary artery pressures. It has also been used in neonates with persistent pulmonary hypertension of the newborn with improved oxygenation and reduced need for extracorporeal membrane oxygenation (ECMO).

### High Frequency Oscillatory Ventilation

High frequency oscillatory ventilation allows recruitment of lung units with higher mean airway pressures while limiting ventilator-induced lung injury by using extremely small tidal volumes and lower peak inspiratory pressures. This allows lungs to be ventilated on the steeper and more compliant portion of the pressure volume curve. Gas exchange occurs with diffusion and pendelluft and patients have to be deeply sedated and paralyzed while on this mode of ventilation.

### Negative Pressure Ventilation

Negative pressure ventilation creates a pressure gradient between the mouth and alveoli by lowering the body surface pressure below atmospheric pressure. This allows air to flow into the lungs without needing endotracheal intubation. The negative pressure is generated around the patient's chest wall or abdomen using a tank (the so-called *iron lung* that was used in polio epidemic in 1950s), body suit or poncho, or as a cuirass or shell. The negative intrathoracic pressures also enhance venous return as opposed to traditional positive pressure ventilators that reduce venous return. This may be an option for patients who require long-term respiratory support but want to avoid the use of a tracheostomy or facial masks used with other noninvasive ventilation devices.

### Extracorporeal Membrane Oxygenation

For patients with severe refractory respiratory failure that is not improving despite high levels of positive pressure support, gas

exchange can be achieved with an artificial membrane instead of the alveolar capillary membranes. This is done by diverting blood flow away from the lungs into an extracorporeal (outside the body) device that can oxygenate the blood and then pump it back into the systemic circulation. This can be done until the lungs recover from the primary insult or disease process that caused respiratory failure in the first place. There are two major configurations through which ECMO support is provided; venoarterial or venovenous. Both approaches require the placement of large cannulas in the major blood vessels to allow blood to be withdrawn and returned to the patient after oxygenation. Systemic anticoagulation is used to prevent clotting of the blood in the circuit but it increases the risk of bleeding as well. It also requires frequent monitoring to ensure the level of anticoagulation is maintained appropriately. Complications from ECMO include infection, bleeding, circuit failure or rupture and fluid retention. Once the patient recovers, ECMO support can be weaned and the patient's vessels are decannulated. Providing ECMO support requires a whole multidisciplinary team of cardiothoracic surgeons, respiratory therapists, intensivists and nurses.

## OUTCOME AND PROGNOSTIC FACTORS

The overall prognosis of children with respiratory failure depends on the underlying cause and predisposing conditions/risk factors mentioned above. Acute respiratory failure related to infectious disorders, when treated with adequate respiratory support while the infection resolves, is generally associated with good outcomes. However, ARI still accounts for the largest number of deaths in children worldwide. For patients with chronic respiratory failure, provision of long-term therapies and supplemental oxygen/positive pressure support (if needed) can help prevent secondary complications. When an acute process/exacerbation causes respiratory failure in someone with an underlying chronic lung or systemic disorder, then prognosis is generally dependent on the severity of the underlying condition.

## PREVENTION

Prevention of respiratory failure involves timely initiation of therapies for ARIs. Ensuring timely and age-appropriate immunizations for common vaccine-preventable diseases is an important public health strategy for all healthy children and is especially important for children with chronic lung, heart or neuromuscular conditions. Use of appropriate controller medications for asthma can help prevent acute severe exacerbations that could progress to respiratory failure if not promptly treated. Preventive care also involves planning of respiratory support for patients with chronic respiratory conditions or progressive neuromuscular disorders. Ongoing monitoring of lung function by spirometry can be helpful in tracking the decline in lung function over time. Most patients with neuromuscular weakness whose forced vital capacity has dropped below 30% of normal predicted values are at risk for nocturnal hypoventilation and may require night time support with BiPAP. If their end tidal  $\text{CO}_2$  level is more than 45 mm Hg while awake or if they have difficulty in breathing along with daytime oxyhemoglobin saturations less than 95%, then further

support may still be needed during daytime as well. Paying close attention to use of airway clearance techniques (postural drainage, huff cough or the use of mechanical insufflation-exsufflation device or CoughAssist) to prevent atelectasis and mucus plugging in patients with neuromuscular disorders can also help to minimize respiratory morbidity. Placement of tracheostomy for use of long-term positive pressure support may be considered for those with chronic respiratory failure with careful weaning of support as the underlying condition improves.

### IN A NUTSHELL

1. Respiratory failure is the inability of the respiratory system to maintain adequate oxygenation of the blood and body tissues, or the loss of its ability to ventilate adequately.
2. The four major causes of hypoxemia are ventilation perfusion mismatch, diffusion block, hypoventilation and shunt.
3. Acute respiratory failure can occur with several respiratory and non-respiratory acute illnesses, while chronic respiratory failure tends to occur in children with underlying conditions that affect ventilation or gas exchange.
4. Clinical assessment of a child in respiratory distress should involve an assessment of their appearance, perfusion to the skin and work of breathing.
5. Differential diagnosis of respiratory failure includes several acute or chronic disorders that cause tachypnea, metabolic acidosis or inadequate tissue perfusion.
6. Arterial blood gases are an important tool for initial assessment as well as for monitoring of the response to therapy in patients with respiratory failure.
7. Management involves treatment of underlying cause and supportive care.
8. Noninvasive ventilatory support should be considered in patients with acute or chronic respiratory failure as a means to avoid intubation.
9. Outcomes for children with respiratory failure depend on the severity of the underlying disease process.
10. Prevention involves protection against respiratory pathogens and prompt recognition of impending respiratory failure to initiate therapies.

## Chapter 8.5

# Mechanical Ventilation

*Dinesh Raj, Rakesh Lodha*

Mechanical ventilation refers to artificially blowing gases into the patients' lungs to maintain oxygenation and remove carbon dioxide. Ventilators have evolved from negative pressure ventilation in the 1950s to the current generation of positive pressure ventilation. During mechanical ventilation, the ventilator either alone or in conjunction with the patient's effort generates a force to move gases into the lungs. For movement of gas through the airways, the force should overcome the elastic and resistive components of the lung, airways, and chest wall. The current era of mechanical ventilation focuses on making the child comfortable on mechanical ventilation, minimizing asynchrony, and using noninvasive route wherever possible. Different strategies of mechanical ventilation in different diseases have improved the outcome of critically ill children. This chapter aims to familiarize the reader with the physiologic basics and different modes of mechanical ventilation. The chapter also discusses the initial settings for various diseases and the common strategies used for common lung conditions needing mechanical ventilation. Indications of mechanical ventilation are listed in **Box 1**.

### BOX 1 Indications of mechanical ventilation

1. Any condition causing hypoxemia and/or hypercarbia [pneumonia, acute severe asthma, acute lung injury (infections, inhalational injuries), respiratory distress syndrome, pulmonary edema, heart diseases like myocarditis, congenital heart disease]
2. Increased work of breathing (septic shock, pneumonia, bronchiolitis, heart diseases)
3. Decreased respiratory drive (head trauma, poisonings, apnea, altered mentation due to any cause)
4. Neuromuscular diseases (Guillain-Barré syndrome, spinal muscular atrophy, etc.)
5. Reduction of raised intracranial pressure in certain conditions
6. Issues related to chest wall, diaphragm and pleura (flail chest, congenital diaphragmatic hernia, pneumothorax, massive pleural effusion)
7. Elective ventilation for surgeries, invasive procedures, etc.
8. Postoperative state.

## PHYSIOLOGY OF GAS EXCHANGE AND LUNG MECHANICS

All the air that is inspired does not take part into gas exchange. The volume of air in the airways which does not take part into gas exchange due to lack of a diffusing membrane is called anatomical dead space. Physiological dead space or total dead space is the combination of anatomical dead space and the alveoli which are ventilated but not perfused. The presence of endotracheal (ET) tube/mask (for noninvasive ventilation) adds to the dead space in ventilated children. Alveolar ventilation is a direct determinant of pulmonary gas exchange. Alveolar ventilation is given by:

$$\text{Alveolar ventilation} = (V_T - V_D) \times \text{RR}$$

where,  $V_T$  is tidal volume,  $V_D$  is dead space and RR is respiratory rate. Alveolar ventilation can be increased by increasing tidal volume or respiratory rate.

The causes of hypoxemia in a ventilated child include ventilation-perfusion mismatch, right to left shunting, diffusion

abnormalities and hypoventilation. Inadequate ventilation relative to perfusion is responsible for ventilation-perfusion mismatch leading to hypoxemia in majority of cases. Determinants of oxygenation include mean airway pressure (MAP) and fraction of inspired oxygen concentration ( $\text{FiO}_2$ ). MAP can be increased by increasing peak inspiratory pressure (PIP), inspiratory time and positive end-expiratory pressure (PEEP), and changing the flow to attain a square waveform. Increase in MAP beyond a certain extent leads to overdistension and may not improve oxygenation.  $\text{CO}_2$  removal depends on alveolar minute ventilation. Increasing the respiratory rate and tidal volume (TV) improves  $\text{CO}_2$  removal. In pressure-controlled ventilation (PCV), TV can be increased by increasing the pressure difference (PIP-PEEP).

The targets for partial pressure of arterial oxygen ( $\text{PaO}_2$ ) and partial pressure of carbon dioxide ( $\text{PaCO}_2$ ) are 50–80 mm Hg and 40–50 mm Hg, respectively. Higher  $\text{CO}_2$  (up to 60 mm Hg) are accepted in certain scenarios, like chronic lung disease, severe hyaline membrane disease (HMD), and acute respiratory distress syndrome (ARDS) as a part of lung protective strategy (permissive hypercapnia). Compliance, an indicator of the elastic property of the lung, is a ratio of the change in volume with change in pressure ( $\Delta V/\Delta P$ ). Compliance can change in different disease processes. Furthermore, it can change during the disease process in a patient, either recovering or worsening. The slope of the pressure volume curve at any point in time gives the compliance at that particular point (**Fig. 1**). Static compliance is measured at zero airflow and dynamic compliance is measured during airflow through the lungs. Dynamic compliance reflects lung and chest wall stiffness, besides airway resistance. In a stiff lung (e.g., pulmonary edema, consolidation), both are low. If only the dynamic compliance has decreased, it means that the airway is obstructed, e.g., ET tube obstruction or bronchospasm.

Airway resistance is the obstruction to airflow in the airways. It is given by the ratio of change in the pressure to airflow ( $\Delta P/V$ ). The resistance to the flow of air through a tube is proportional to the length of the tube and inversely proportional to the fourth power of radius, as given by the Poiseuille's equation. The airway resistance is affected by the lumen/patency of the airways, presence of secretions, ET tube characteristics, and airway tone. Increase in airway resistance leads to increase in work of breathing. The largest appropriately sized ET tube (as per age) should be put and patency maintained to keep airway resistance minimum.

**Figure 1** Pressure-volume curve—compliance curve  
Abbreviation: FRC, functional residual capacity

The condensations in the ventilator circuits should be avoided. Airway resistance can be monitored on a ventilated child using the pressure-volume (PV) loops (discussed later).

Time constant is the product of compliance and resistance. It is a measure of the time taken for pressure to equilibrate between the proximal airways and the alveoli. In simple terms, it indicates how quickly the lungs can inflate and deflate. Inspiratory time constant is nearly half as long as expiratory time constant. In diseases with longer time constants, meconium aspiration, e.g., the inspiratory time should be kept adequate to allow TV to be delivered, and adequate expiratory time for exhalation. Respiratory distress syndrome (RDS), on the other hand, is typically associated with shorter time constants.

## EQUATION OF MOTION

The relation between volume of gas ( $\Delta V$ ) going to any part of the lung, gas flow ( $V$ ) and applied pressure ( $\Delta P$ ) is given by the equation

$$\Delta P = \Delta V/C + V \times R \times k$$

where  $C$  is lung compliance,  $R$  is airway resistance and  $k$  is a constant, which defines the end expiratory pressure. This equation is known as the equation of motion for the respiratory system. In simple terms, the pressure (exerted by the respiratory muscles and ventilator) should overcome the elastic load ( $\Delta V/C$ ) and the resistive load ( $V \times R$ ). Elastic load is the pressure needed to overcome the chest wall recoil, and resistive load is the pressure needed to overcome the flow of air through the airways. From this equation of motion, we can see that change in pressure will lead to change in volume and flow, if the compliance and resistance are constant; similarly, if volume is changed, pressure and flow will change.

## VENTILATION CONTROLLERS

Inspiration is controlled in mechanical ventilation, whereas expiration is passive. The four variables which can be controlled during inspiration are pressure, volume, flow and time. And the manner in which each of these is controlled, decides the mode of ventilation.

### Pressure Control (Fig. 2)

A constant pressure is maintained during inspiration irrespective of the compliance and resistance of the respiratory system. During PCV, volume and flow are dependent variables. With changes in compliance and resistance, the delivered TV may vary. The flow utilized is of a decelerating pattern, with high flow in initial part of inspiration with gradual decline. The expiration starts after the inspiratory time is completed. In the current ventilators, once flow decreases to a predetermined fraction (usually 25%) of the initial flow, expiration ensues (flow cycling).

### Flow/Volume Control (Fig. 3)

In flow control, the flow is controlled as a function of preset TV. Flow control is also called volume control by some as a preset volume is delivered. However, flow control is an appropriate term as these ventilators measure flow and calculate volume from flow measurement. The flow and volume remain constant with variable pressure. A comparison of volume and pressure control is given in Table 1.

### Phase Variables

Phase variables control the various phases of the respiratory cycle, i.e., initiation of inspiration, maintaining inspiration, switching from inspiration to expiration, and through expiration.

**Figure 2** Scalar waveforms for pressure-controlled ventilation  
Abbreviations: PEEP, positive end-expiratory pressure; PIP, peak inspiratory pressure; Ti, inspiratory time; Te, expiratory time

**Figure 3** Scalar waveforms for volume-controlled ventilation  
Abbreviations: PEEP, positive end-expiratory pressure; PIP, peak inspiratory pressure; TV, tidal volume; Pplat, plateau pressure

### Trigger Variable

Trigger variable is responsible for the initiation of the inspiration. Mandatory breaths initiated by the ventilator are time-triggered. However, ventilator can assist the breaths initiated by the patient by sensing change in pressure or change in flow. In pressure triggering, the ventilator detects a drop in pressure in the circuit and initiates inspiration. In flow triggering, the ventilator detects a reduction in flow in the expiratory limb of the circuit. The trigger setting needs to be set appropriately as a very sensitive setting may result in inappropriate ventilator triggering with even cardiac pulsations. On the other hand, an insensitive trigger setting may increase the

**Table 1** Comparison of volume control and pressure control ventilation

	Volume control	Pressure control
Tidal volume	Set	Variable
Airway pressure	Variable	Set
Inspiratory flow	Constant	Decelerating
Minute ventilation	Set	Variable
Advantages	Less risk of volutrauma Automatic weaning as compliance improves	Less risk of barotrauma Initial high flow (decelerating flow) better for stiff lungs
Disadvantages	Risk of barotrauma in stiff lungs with unmonitored peak pressures Flow starvation in air hungry patients due to constant flow	Variable tidal volume Volutrauma can result if peak inspiratory pressure not decreased with improvement in compliance

patient's work of breathing. Work of breathing and patient's comfort are better with flow triggering as lesser effort is needed for changing flow than for changing the pressure in the circuit.

#### Limit Variable

During inspiration, if a variable is not allowed to exceed a preset level, it is referred to as a limit variable. The limit variable once reached is maintained during inspiration. Pressure, volume or flow is used as a limit variable.

#### Cycle Variable

Cycle variable determines the switch from inspiration to expiration. The commonly used cycle variable is time. Pressure, volume and flow can also be used as cycle variable. Using flow as a cycle variable facilitates synchronization of expiration.

#### Baseline Variable

The variable controlled in expiration is called baseline variable, i.e., end-expiratory pressure.

### VENTILATOR TERMINOLOGY (FIG. 4)

#### Peak Inspiratory Pressure

It is the maximum pressure during the inspiratory phase of the breath ventilating the child. PIP is needed to inflate alveoli and improve oxygenation. High PIP may lead to barotraumas.

#### Positive End-expiratory Pressure

It is the pressure maintained in airways at the end of exhalation to keep alveoli open. PEEP is needed to improve functional residual capacity, oxygenation, and avoiding reopening and closing of alveoli which can cause atelectotrauma. Excessive PEEP can lead to overdistension, and reduced venous return and TV.

#### Respiratory Cycle

One respiratory cycle includes inspiration and expiration. The duration for which patient is inhaling is inspiratory time. The duration for which patient is in expiration is expiratory time. I:E ratio is the ratio of inspiratory time and expiratory time. Normally, I:E ratio is kept at 1:2. Inverse ratio ventilation may be needed in ARDS to improve oxygenation.

**Figure 4** Pressure-time waveform for volume-controlled ventilation  
Abbreviation: PEEP, positive end-expiratory pressure

#### Tidal Volume

Volume of each breath, set in volume-controlled ventilation (VCV). It is needed for oxygenation and CO<sub>2</sub> removal.

#### Rise Time

The beginning of a breath can be either fast or slow depending on the flow rate. A faster rise is needed for patients who are air hungry. A slower rise provides laminar flow and better gas distribution.

#### Mean Airway Pressure

The average airway pressure during one complete respiratory cycle is known as mean airway pressure and is given by:

$$MAP = \frac{K (Ti \times PIP) + (Te \times PEEP)}{Ti + Te}$$

where k is a constant depending on the shape of the waveform, Ti is inspiration time and Te is expiration time. Increasing MAP improves oxygenation.

#### Plateau Pressure

Plateau pressure (Pplat) is the pressure at equilibrium applied to small airways and alveoli during inspiration. In normal lungs, PIP is slightly above Pplat. With increasing TV and worsening compliance, both PIP and Pplat increase proportionately. Increased airway resistance due to any cause leads to increase in PIP with no change in Pplat.

#### Intrinsic Positive End-expiratory Pressure/ Auto-positive End-expiratory Pressure

If the expiratory time is not long enough, the exhalation may not be completed. A fresh breath may be given to the patient while the expiratory flow has not become zero. This leads to air trapping and auto-PEEP. Auto-PEEP also increases the work of breathing as the patient has to generate pressure above the sum of auto-PEEP and trigger pressure to trigger a breath from the ventilator.

#### FiO<sub>2</sub>

It is the fraction of inspired oxygen. It can range from 0.2–1.

### TYPE OF BREATHS

Type of breaths in a ventilated patient could be mandatory, assisted or spontaneous. If inspiratory cycling is determined by the ventilator, such a breath is designated as mandatory breath, which is initiated and terminated by the ventilator. If the breath is triggered by the patient, it is referred to as triggered or assisted breath. In spontaneous breathing, cycling (inspiratory and expiratory) and

limit, both are determined by the patient. In supported breaths, inspiratory and expiratory cycling is determined by the patient, but the breaths are supported by the ventilator to a preset limit.

## MODES OF VENTILATION

### Intermittent Mandatory Ventilation

Intermittent mandatory ventilation is a ventilation mode in which the machine delivers control (mandatory) breaths and allows the patient to take spontaneous breaths in between. As machine frequency is preset and independent of the patient's own efforts, breath stacking may occur. The control could be either volume control or pressure control. IMV has now been replaced by more sophisticated modes which allow synchronization and other benefits.

### Synchronized Intermittent Mechanical Ventilation

Synchronized intermittent mandatory ventilation (SIMV) is a ventilation mode which gives either assisted breaths (patient-triggered) or time-triggered machine breaths. The control could be either pressure or volume control. Just prior to time-triggered breath, there is a synchronization window, during which if the patient triggers a breath, it is assisted. If no effort is observed from the patient, the machine delivers the time-triggered breath. In between mandatory breath, patient is free to take spontaneous breaths which are limited by the patient. Synchronization prevents breath stacking (i.e., mandatory breath over and above spontaneous breath). SIMV has the advantages of lowering MAP, decreasing respiratory muscle atrophy and facilitating weaning. The disadvantages include rapid weaning leading to muscle fatigue. However, this can be offset by adding pressure support to SIMV. SIMV is indicated in actively breathing patient to provide partial ventilatory support.

### Assist/Control Ventilation

Assist ventilation (AV) is a ventilation mode in which patient determines the respiratory rate and minute ventilation. It is used in patients with a spontaneous and stable respiratory drive. The ventilator delivers a breath of a preset TV in response to patient's trigger (assist). If the patient triggers less than the set frequency, the machine delivers time-triggered mandatory breaths (control). The patient is not allowed to breathe spontaneously. Advantages include decreased work of breathing, and ability to control the minute ventilation by the patient. However, it can lead to respiratory alkalosis in an anxious child due to excessive triggering, as all breathing efforts detected will trigger the ventilator to deliver the breath. AC mode can be used to provide full ventilatory support in a child with a stable drive.

### Pressure Support Ventilation

Pressure support ventilation (PSV) is a ventilation mode which allows supporting of spontaneous breaths with pressure; the child triggers the breath and controls the cycling to expiration by change in flow. The breaths are supported to a preset pressure support level, and terminated when the patient's inspiratory flow demand decreases below a threshold. Herein, the patient controls the rate, TV and flow. Advantages include decreased work of breathing and enhanced patient comfort due to spontaneous breathing. It can also be used as a weaning tool by a gradual reduction in pressure support. However, it can only be used in a spontaneously breathing individual.

### Pressure-regulated Volume Control

Pressure-regulated volume control (PRVC) is a dual control mode of mechanical ventilation in which a preset TV is delivered at the lowest possible PIP by alterations in flow rate

and inspiratory time. In conventional VCV, the flow is constant, so increase in airway resistance leads to increase in PIP to deliver the volume. However, in PRVC, with an increase in airway resistance, the flow decreases to prevent PIP from rising, but to deliver the set volume, inspiratory time is increased. In a way, both pressure and volume can be controlled in PRVC. The advantages of PRVC include delivering a constant TV while minimizing PIP. However, ventilator support may be decreased in patients breathing at a high respiratory rate. PRVC can be utilized in patients with fluctuating lung mechanics.

### Continuous Positive Pressure Ventilation

This is not a ventilation mode but a commonly used respiratory support modality. Continuous positive pressure ventilation (CPAP) delivers PEEP above the atmospheric pressure. CPAP internally splints the lungs and prevents the alveoli from collapsing. There is improvement in lung compliance and reduction in work of breathing. Alveolar recruitment improves oxygenation and prevents atelectasis. However, hyperinflation and air leaks may occur if PEEP is kept inappropriately high. CPAP can be administered noninvasively on spontaneously breathing patients by nasal and oronasal/nasopharyngeal route. CPAP is indicated in postextubation states, mild HMD, apnea of prematurity, and weaning-prolonged ventilator-dependent infants.

### Bilevel Positive Airway Pressure

Bilevel positive airway pressure (BiPAP) is similar to CPAP with the difference being those two different levels of pressure for inspiration and expiration. Due to the difference in levels of pressure, positive pressure breath is delivered. The switch from one level to other is synchronized with the patient. The triggering in BiPAP can be spontaneous, spontaneous/timed or timed. BiPAP can be used noninvasively to support children with chronic problems like neuromuscular disorders, obstructive sleep apneas, and obesity-hypoventilation syndromes. It can also be utilized in acute conditions including pulmonary edema and pneumonia.

## VENTILATOR SETTINGS

**Table 2** highlights the parameters to be adjusted in pressure- and volume-controlled modes and the initial settings. However, the strategy for different lung diseases is different and initial settings should take into consideration the underlying lung pathology. The various parameters determining oxygenation and CO<sub>2</sub> removal are given in **Table 3**.

## MECHANICAL VENTILATION IN CERTAIN COMMON SCENARIOS

### Ventilation of Nondiseased Lungs

Ventilation of children with healthy lungs is usually not difficult. Not much can be attained by choosing one mode over another. Ventilation can be done using physiological rates with either volume or pressure mode. A TV of 6–8 mL/kg is appropriate. If pressure mode is chosen, a pressure level guided by adequate chest rise and optimal saturation is acceptable; this is usually 8–10 cm H<sub>2</sub>O above PEEP. Physiological PEEP of 3–4 cm H<sub>2</sub>O is appropriate. Inspiratory time should also be based on the age of the child (0.4 sec for newborns and infancy, 0.6 sec for toddlers and preschool children, and 0.8–1 sec for older children and adolescents).

### Asthma

Asthma is characterized by increased airway resistance due to bronchospasm, mucosal edema and airway secretions. Obstruction

**Table 2** Initial settings for pressure- and volume-controlled mode

Settings	Pressure-controlled mode	Volume-controlled mode
Rate	Age-related	Age-related
PEEP	3–5 cm H <sub>2</sub> O (lower for obstructive diseases)	3–5 cm H <sub>2</sub> O (lower for obstructive diseases)
Volume	-	6–10 mL/kg
PIP	Titrate to chest rise	-
Ti	Usually I:E ratio of 1:2, can increase Te in case of obstructive diseases	Usually I:E ratio of 1:2, can increase Te in case of obstructive diseases
FiO <sub>2</sub>	Target adequate oxygenation	Target adequate oxygenation

Abbreviations: FiO<sub>2</sub>, fraction of inspired oxygen; PEEP, positive end-expiratory pressure; PIP, peak inspiratory pressure; Ti, inspiratory time; Te, expiratory time.

to airflow predominantly during expiration is the problem in asthma. Hence, ventilating a child with obstructive lung disease is difficult because in conventional mechanical ventilation, expiration is passive. The idea is to prolong expiration by keeping low rates with long expiratory time; the initial rates are usually about half the physiological rates. Air trapping (auto-PEEP) is to be avoided. Low levels of PEEP are advised. PCV is avoided as the TV delivered may vary greatly with changes in airway resistance and bronchospasm. VCV with constant flow may be better than pressure modes. VCV also allows the measurement of PIP and Pplat which can be used to assess response to therapy. Permissive hypercapnea should be targeted accepting pH as low as 7.2. Sedation and neuromuscular blockade may be required to minimize air leaks. Ketamine and fentanyl are the preferred drugs for sedation.

### Acute Lung Injury/Acute Respiratory Distress Syndrome

Acute lung injury (ALI)/ARDS is characterized with decreased lung compliance leading to respiratory failure. Although diffuse infiltrates (whiteout in some cases) are evident on chest radiographs, the pattern of involvement is heterogenous with a predominant involvement of dependent regions and sparing of nondependent regions. As there are areas of atelectasis and consolidation interspersed with normal lung parenchyma, the ventilation is difficult and prone to ventilator-induced lung injury (VILI). Alveoli in the dependent areas or consolidated part of lung have a closing volume near end-expiration leading to alveolar collapse. These alveoli need to be reopened during inspiration. The repeated opening and closing lead to alveolar damage (atelectrauma). The strategy in ALI is to recruit lungs and keep the alveoli patent. This can be done using optimal PEEP which is needed to keep lung open and preventing atelectrauma. As a general principle, one can begin with a PEEP of 6–8 cm H<sub>2</sub>O and increase in increments of 1–2 cm H<sub>2</sub>O till adequate oxygenation (saturation of 90–92%) is attained. FiO<sub>2</sub> should be kept at 60% or below to prevent oxygen toxicity. Low TV (4–6 mL/kg) with low Pplat (< 30 cm H<sub>2</sub>O) are used to prevent volutrauma and barotraumas. These lung protective strategies can cause hypercapnea which is acceptable provided the pH is above 7.2 (permissive hypercapnea).

### Pneumonia

The principle of ventilation in pneumonia is similar to that of ALI/ARDS. The approach is to titrate the FiO<sub>2</sub> and PEEP to the severity and extent of the lung disease.

**Table 3** Measures to increase oxygenation and ventilation

Oxygenation	
Parameter	Comment
<b>Oxygenation</b>	
FiO <sub>2</sub>	Increasing FiO <sub>2</sub> beyond 0.6 increases oxygen toxicity
Mean airway pressure ↑ PIP ↑ PEEP ↑ Ti ↑ Flow (square waveform) ↑ Rate	High PIP may cause barotrauma High PEEP may decrease venous return May need to decrease rates Square waveform increases barotrauma May lead to auto-PEEP
<b>Ventilation</b>	
Minute ventilation ↑ TV (↑ΔP)  ↑ Rate ↑ Flow ↓ Te	High PIP causes barotrauma, low PEEP affects oxygenation and causes alveolar collapse May lead to auto-PEEP Increases barotrauma Leads to decrease in Ti causing ↓MAP/oxygenation

### Air Leak

While ventilating a child with air leak, the aim should be to reduce MAP as much as possible. FiO<sub>2</sub> can be increased to attain optimum oxygenation. Higher rates may be tried as alveoli have much shorter time constant than the interstitial air. If reduction in MAP is not tolerated, high frequency oscillatory ventilation (HFOV) may be attempted.

### WEANING OFF THE VENTILATOR

Weaning is defined as the transition from ventilatory support to complete spontaneous breathing. At the end of weaning, patient should be able to breathe spontaneously to maintain adequate gas exchange, following which the patient can be extubated. On one hand, prolonged ventilation is associated with complications [VILI, ventilator associated pneumonia (VAP), glottic edema], premature extubation can also be risky. The duration of weaning may be affected by a number of factors. The underlying disease for which ventilation was needed has a bearing on the duration of weaning. Weaning for elective ventilation for procedures or ventilation in the postoperative period may be rapid. However, ALI/ARDS may have to be weaned slowly once the stormy phase is over. Critically, ill children develop fluid overload which may decrease lung compliance affecting oxygenation and may prolong/delay weaning. Level of sedation may also affect extubation readiness. Presence of pulmonary hypertension and compromised cardiac function may also complicate weaning. **Box 2** lists some of the prerequisites for weaning.

#### BOX 2 Prerequisites for weaning

1. Cause of respiratory failure is passive or has improved substantially
2. Adequate oxygenation—able to maintain arterial oxygen saturation and partial pressure of arterial oxygen above 90% and 60 mm Hg, respectively on a fraction of inspired oxygen of < 0.4
3. Hemodynamic stability
4. Absence of anemia
5. Adequate mental status.

## Techniques of Weaning

Gradual reduction of ventilatory support (SIMV) is the commonly used technique of weaning as SIMV permits spontaneous breaths between machine breaths. The frequency of mandatory breaths is gradually reduced by 1–3 breaths per minute at each step. During this period, saturation must be monitored, and  $\text{PaCO}_2$  must be measured 30 minutes after decreasing the rates. The rapidity with which the rates can be lowered depends on the cardiopulmonary function of the patient. Once a frequency of mandatory breaths of 10–15 breaths per minute is reached, and blood gases and vital parameters are normal, the weaning prerequisites are fulfilled, extubation can be attempted.

### Spontaneous Breathing Trials

Spontaneous breathing using T-tube is frequently used for weaning. Spontaneous breathing trials (SBT) are usually tried either alone or with low levels of pressure support (5–7 cm  $\text{H}_2\text{O}$ ) or with CPAP for around half-an-hour. Most patients who fail an SBT usually do so within 20–30 minutes.

### Pressure Support Ventilation

Pressure support ventilation either alone or in combination with SIMV is sometimes used to facilitate weaning. PSV is started at around 5–10 cm  $\text{H}_2\text{O}$  and titrated upward to achieve a desired spontaneous TV (10–15 mL/kg) and desired frequency of 25/min or less. If patient tolerates this well, then pressure support can be gradually reduced.

### Automatic Tube Compensation

Sometimes, the resistance due to artificial airway increases the work of breathing, hampering weaning process. Automatic tube compensation available in some ventilators alleviates the resistance due to artificial airway, facilitating spontaneous breathing.

## Weaning Failure

Weaning failure is defined as the need to be put back on the ventilator (either as a failure of spontaneous breathing trial, or need to reintubate within 48 hours of extubation). Weaning failure is associated with signs of increased work of breathing (tachypnea, accessory muscle use, paradoxical abdominal breathing). The patient may have developed altered mentation, become agitated and diaphoretic.  $\text{CO}_2$  retention, hypoxemia and hypo/hypertension may develop. If the child fails a trial of spontaneous breathing, he should be put back on ventilation and one should wait for 24 hours to attempt a fresh SBT. For these children, other modalities of weaning may be tried including PSV and/or SIMV.

### Cuff Leak Test

As upper airway obstruction is one of the commonest causes of extubation failure, cuff leak test may be done to predict stridor postextubation. After deflating the cuff, an attempt is made to hear leak around the ET tube. A leak audible to the ear with the patient's head in neutral position may predict successful extubation.

## MONITORING

Meticulous monitoring is important to optimize respiratory support and prevent the potential complications of mechanical ventilation. Continuous monitoring of child's vital parameters, including heart rate, respiratory rate, oxygen saturation and blood pressure, is required. End-tidal  $\text{CO}_2$  monitoring if available is desirable. Clinical evaluation at regular intervals to assess child's respiratory efforts, air entry, capillary refill, increased work of breathing, and asynchrony with ventilation should be done. Arterial blood gas should be done to monitor  $\text{PaO}_2$  and  $\text{PaCO}_2$  at least 12 hourly or

half hour after change of settings. Chest radiograph may be needed at frequent intervals to assess the disease status, detection of complications, and the position of ET tube. Pulmonary graphics monitoring allows assessment of the change in mechanics of the respiratory system.

## Ventilator Graphics Monitoring

Ventilator graphics monitoring (**Box 3**) allows real-time measurements of the patient-ventilator interactions. Flow, volume and pressure are measured and displayed real time. From these measurements, compliance, resistance and work of breathing can be calculated. There are two types of graphics: scalars and loops. Scalars represent waveforms of pressure, volume or flow (y-axis) versus time (x-axis). Loops represent waveforms of pressure versus volume or flow versus volume.

### BOX 3 Ventilator graphics

1. Scalar waveforms: control variables (y-axis) versus time (x-axis)
  - Pressure waveform
  - Flow waveform
  - Volume waveform
2. Loop waveform: one control variable plotted against another
  - Pressure-volume loop
  - Flow-volume loop
3. Calculated values
  - Compliance
  - Resistance.

### Pressure Waveform

The shape of the pressure-time waveform depends on the breath type (square in PCV, and triangular in VCV). A negative deflection just preceding inspiration suggests triggering. Peak pressures and Pplat can also be estimated by measurements on the y-axis. Changes in compliance and resistance can affect the level of peak pressure and Pplat attained in VCV. The area under curve of the pressure waveform is the MAP. A significant rise in peak pressure relative to Pplat suggests airway obstruction. **Figures 2 and 3** depict pressure-time scalars for pressure and VCV, respectively.

### Flow Waveform

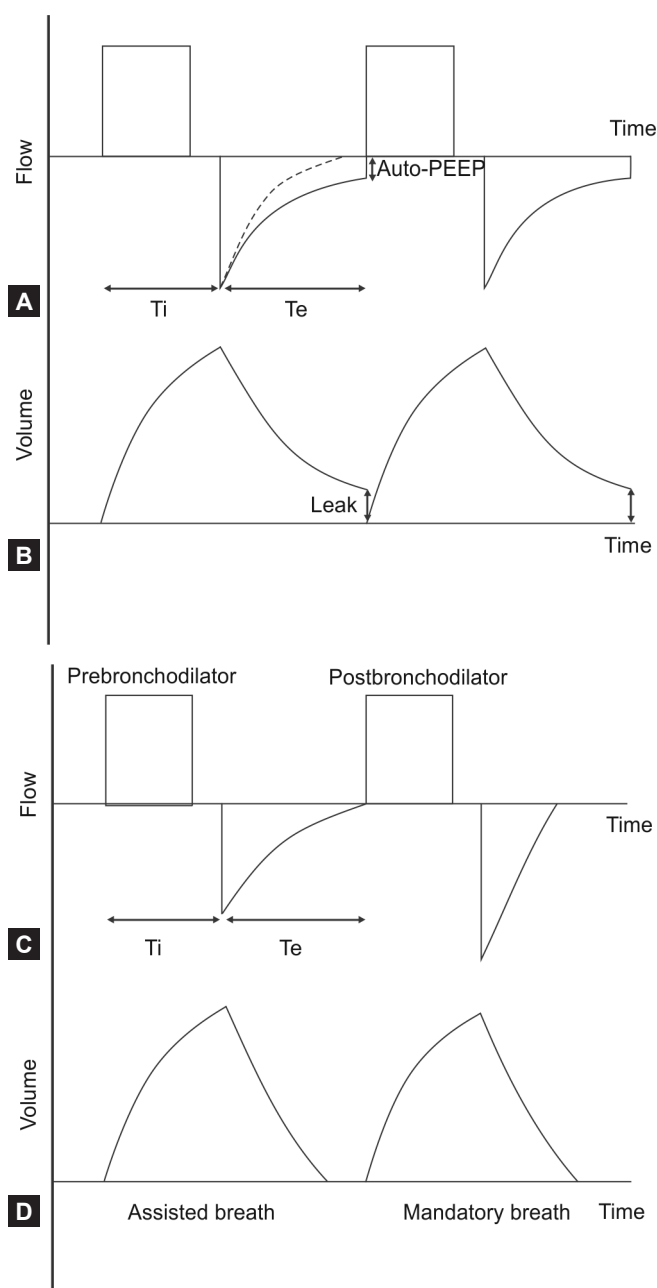

The type of flow, and hence the breath type, can be identified by looking at the flow waveform. Flow is decelerating in PCV and constant in VCV. Auto-PEEP can be identified if the expiratory flow is not reaching baseline. If the expiratory flow is deeply curved and takes long to reach baseline, it suggests airway obstruction. Decreased peak expiratory flow suggests air leak. Rise time can also be assessed by looking at the inspiratory flow limb. **Figures 2 and 3** depict flow-time scalars for pressure and VCV, respectively.

### Volume Waveform

The upstroke in volume waveform indicates inspiration and downstroke indicates expiration. Failure of the expiratory limb to reach baseline suggests ET leak, bronchopleural fistula, or auto-PEEP. **Figures 2 and 3** depict volume-time scalars for pressure and VCV, respectively. **Figures 5A to D** shows the information provided by scalars in monitoring patients on mechanical ventilation.

### Pressure-volume Loops

The slope of the PV loop indicates the elasticity of the lung. The difference in the inspiratory and expiratory limb of the PV loop, also known as hysteresis, indicates the resistive work of breathing. **Figure 6** depicts the loops observed in different breath types. The changes in compliance and resistance can be picked up by a careful look at the PV loops. With overdistension, the terminal

**Figures 5A to D** (A) Auto-PEEP; (B) Leak; (C) Bronchodilator response; (D) Assisted breath

**Abbreviations:** PEEP, positive end-expiratory pressure;  $T_i$ , inspiratory time;  $T_e$ , expiratory time.

part of the inspiration assumes a beaked shape due to less volume change with the change in pressure (**Fig. 7**). With decrease in lung compliance in PCV, the loops shift downward and to right leading to fall in TV, while reverse is seen with improvement in lung compliance. However, in VCV, with decreased compliance the loop is shifted to right but needs higher pressure to achieve same volume (**Fig. 8**).

### Flow-volume Loops

The flow-volume loops depict the pattern of airflow during breathing (**Fig. 9**). The curve above x-axis is inspiratory limb and

**Figure 6** Pressure-volume loops for different types of breaths

**Figure 7** Pressure-volume loop depicting the upper and lower inflection points and overdistension

the one below x-axis is the expiratory limb. Alteration in airway resistance due to various causes can be identified from these loops. Leak can be identified if the expiratory limb achieves the baseline prematurely. Presence of secretions leads to irregularities in the inspiratory limb.

### HIGH-FREQUENCY VENTILATION

High-frequency ventilation (HFV) utilizes supraphysiologic frequencies with small TV close to or below the anatomical dead space. As the TVs are small (around 1–3 mL/kg), peak pressures are low, and maximal MAP and alveolar recruitment in HFV is one of the lung protective strategies. HFOV is the common mode of HFV used in neonates and children. HFOV employs an oscillatory diaphragm which generates a rapidly altering gas flow to provide active inspiration and expiration. As the diaphragm moves back and forth, gas is pushed into the lungs and actively withdrawn. The frequency with which the diaphragm moves is the breathing frequency, and the magnitude of oscillations is called amplitude (or  $\Delta P$ ).

**Figure 8** Effect of change in compliance on pressure-volume loops for pressure-controlled ventilation (left) and volume-controlled ventilation (right)

Abbreviations: TV, tidal volume; PIP, peak inspiratory pressure.

The mechanism by which gas exchange is achieved in HFV is complex and differs from conventional ventilation. Initiation of HFOV can be associated with hypotension and hemodynamic instability because of the increased MAP leading to decreased venous return. Therefore, it is recommended that patient be hemodynamically stable and volume loaded before switching to HFOV.

High frequency oscillatory ventilation is generally used as a rescue mode in patients who fail on conventional ventilation primarily due to poor oxygenation. HFOV has been used with success in ALI and persistent pulmonary hypertension of the newborn (PPHN). Use in obstructive diseases should be cautious as HFOV may lead to intrinsic PEEP and active expiration may not be very effective in these scenarios.

The settings of HFOV include frequency, amplitude, MAP, percent inspiration, inspiratory bias flow and  $\text{FiO}_2$ . Oxygenation can be increased by increasing MAP and  $\text{FiO}_2$ .  $\text{CO}_2$  elimination is achieved by decreasing the frequency or by increasing the amplitude, inspiratory time and bias flow.

## COMPLICATIONS OF MECHANICAL VENTILATION

### Ventilator-induced Lung Injury

Ventilator-induced lung injury is the lung damage secondary to positive pressure ventilation. Mechanisms of VILI include physical disruption of cellular membranes and alveolar spaces due to mechanical forces and aberrant cellular response leading to inflammation. Degree of lung inflation is an important determinant of lung injury. Volutrauma and barotrauma, both are implicated in VILI. Atelectrauma, due to repeated opening and causing (recruitment-derecruitment) of alveoli is also implicated in VILI when ventilating at lower lung volumes. High inspired oxygen, due to oxidant stress, also contributes to lung injury. To

prevent VILI, oxygen must be judiciously used, PEEP should be optimal, Pplat must be limited, and overdistension should be avoided.

### Ventilator-associated Pneumonia

Nosocomial pneumonia diagnosed in patients ventilated for 48 hours or more with signs of a new lower respiratory infection is known as VAP. VAP occurs in 3–20% of all mechanically ventilated children, and risk of VAP increases at around 1% per day of ongoing ventilation. The risk factors of VAP include colonization of upper respiratory tract, microaspiration of oropharyngeal secretions and contaminated equipment or aerosolized medications. Prevention of VAP includes elevation of head end by 30 degrees, avoidance of gastric distension by nasogastric tubes, frequent oropharyngeal suctioning, oral hygiene with antiseptics, in-line suctioning, and changing ventilator circuits only when visibly soiled or malfunctioning.

### Air Leaks

Respiratory epithelium can rupture during positive pressure ventilation leading to air entering the lung parenchyma or the pleural space. From the lung parenchyma, air can track proximally along the bronchovascular bundle causing pulmonary interstitial emphysema, and subsequently pneumomediastinum and pneumopericardium. Escape of air into the pleural cavity causes pneumothorax. A pneumothorax must be considered when a child has deterioration in respiratory function. If pneumothorax is suspected in a child with cardiorespiratory compromise, immediate needle decompression must be attempted, followed by a chest drain insertion. If even after 48 hours of putting the chest drain the lung does not reexpand or air continues to bubble through the drain, a bronchopleural fistula is the likely possibility.

**Figure 9** Patterns of flow-volume loops observed in different scenarios  
 Abbreviations: VCV, volume-controlled ventilation; PCV, pressure-controlled ventilation; PEEP, positive end-expiratory pressure.

### IN A NUTSHELL

1. Mechanical ventilation is of utmost importance in the management of critically ill children.
2. As there are multiple ventilator modes, it is desirable to understand how the modes operate, in terms of inspiratory/expiratory cycling, control, limit and feedback.
3. As compliance and resistance of the respiratory system can change with time, ventilator graphics monitoring which allows real-time measurements of the patient-ventilator interactions should be utilized to optimize ventilator settings.
4. High-frequency ventilation is increasingly being used as a rescue mode in patients who fail on conventional ventilation primarily due to poor oxygenation, especially in ALI, air leaks and PPHN.
5. Although mechanical ventilation is life-saving, it can lead to complications (VILI, air leak, VAP), which can be prevented by close monitoring.
6. Pressure control mode utilizes a decelerating flow pattern which is useful in stiff lungs and air hungry patients.
7. Volume control has the benefits of automatic weaning with improvement in compliance.
8. Pressure-regulated volume control, a dual control mode, delivers a preset TV at the lowest possible PIP by alterations in flow rate and inspiratory time, thereby minimizing barotrauma.
9. Mechanical ventilation in acute asthma involves low rates with prolonged expiratory time and low PEEP.
10. Strategy of ventilation in ALI/ARDS involves low TV and optimal PEEP to recruit lungs and keeping the alveoli patent.

## Chapter 8.6

# Sedation and Analgesia

Venkat Shankar

The field of pediatric procedural sedation and analgesia has seen a rapid evolution in the last 20 years. There is an increased awareness among health care providers and parents that even the smallest of the infants perceive pain and anxiety. Increasingly, parents insist on being present and witnessing the procedures being performed on their children and have rising expectations of a relative anxiety and pain-free experience for the child and family. Additionally, the number of invasive and noninvasive procedures performed on children outside the operating room environment has grown exponentially in the recent years fuelling the need for safe, effective and efficient sedation and analgesia. Consequently, a large number of nonanesthesiologists are called upon to provide these services.

Till recently, the area of pain perception in young infants and newborns did not receive much attention. On the other hand, there have been concerns about the safety of administering potent sedatives and analgesics to children due to the potential of respiratory depression and airway compromise. Moreover, unlike adults, children can often be physically overpowered by adult health care providers for restraining them for a painful procedure and culturally it seems that many providers justify inadequate sedation and analgesia by accepting that “it is natural for children to be afraid and cry”. Children are often not in a position to refuse consent or even express their fears and apprehension.

There are many different models and systems of providing procedural sedation and analgesia to children that use different resources, manpower and drugs. In this chapter, some fundamental principles involved in providing safe, effective, predictable sedation in varying settings are described.

### Goals of Procedural Sedation

A good procedural sedation plan attempts to achieve many of these goals (**Box 1**). One should customize the specific sedation or analgesia plan for each situation based on factors like the child's age, co-morbidity, developmental maturity, nature and length of procedure.

#### BOX 1 Goals of procedural sedation

- Allay the fear and anxiety in both the child and the parents
- Induce unawareness and amnesia, if needed
- Obtain the cooperation of the child
- Achieve the necessary degree of immobilization
- Minimize pain and discomfort
- Keep the child safe during sedation
- Minimize the residual effects of sedation after the procedure.

### LEVELS OF SEDATION

Often the term *conscious sedation* is used incorrectly to describe any level of sedation that does not require an endotracheal intubation and respiratory support. As a matter of fact, the term *conscious sedation* is an oxymoron for most pediatric settings and should not be used. Many leading organizations have agreed to a standardized definition for four levels: minimal, moderate and deep sedation, and general anesthesia. These four are not discrete categories, but they are a continuum of a spectrum where a child could easily lapse from one level of sedation to a much deeper one without any warning (**Table 1**). An important fact to remember is that these levels are not specific to any drug and virtually any level

of sedation can be achieved by any agent or any route. The term conscious sedation is no longer recommended as in most children the goal of procedural sedation is to achieve a state where the child is non-responsive to vocal commands and stays still during interventions. This level is more accurately described as deep sedation.

### Skills Training

It is not feasible in most situations to have trained anesthesiologists perform all procedural sedation. Consequently, there is a need to train and ensure appropriate skills for the providers who are doing procedural sedation in children. A large amount of literature exists about skills training and competency verification for various levels of providers.

The person performing the procedure should preferably not be the primary person providing sedation and monitoring the patient. The person performing sedation should not be distracted by other tasks that impair his ability to remain focused on the child's cardiorespiratory status. The individual performing sedation or monitoring the sedated patient should be skilled in recognition of early signs of airway obstruction and hypoventilation or apnea and able to intervene by maintaining airway patency and providing adequate assisted ventilation. The person should have familiarity with the pharmacology of the sedative agents and their antagonists. It is also recommended that any person who intends to provide sedation at a particular level should be skilled enough to rescue the child from next deeper level of sedation.

### PATIENT SELECTION AND SCREENING

Appropriate patient selection is essential for ensuring safe and effective sedation for any situation. It is essential for a focused, standard assessment of the child before the plan for sedation is finalized. It is helpful to follow the American Society of Anesthesiologists (ASA) physical status classification guidelines to stratify the risk of sedation (**Table 2**). A brief and focused evaluation of child should include few essential elements of medical history (**Table 3**) and physical examination (**Table 4**). A child classified as ASA physical status IV or higher should be referred to anesthesiologist for safe administration of sedation or analgesia. Such structured presedation assessment systems have been shown to correlate with good clinical outcomes and reduction of adverse events in the hands of nonanesthesiologists.

It is recommended to follow the commonly accepted fasting guidelines to minimize the risk of vomiting and aspiration (**Table 5**). However, in many emergent situations, it is difficult to wait for the appropriate period of fasting and delay an essential procedure. In such cases, the risk versus benefits of sedation must be assessed to decide about the appropriate plan, and this should be discussed with the family. Based on this assessment, the available options could be: 1. Delay the procedure, 2. Use a lighter level of sedation, if appropriate, 3. Use general anesthesia after securing the airway using a rapid sequence endotracheal intubation.

### EQUIPMENT AND MONITORING

All appropriate equipment and supplies needed for airway management and resuscitation of a pediatric patient should be available at the location of the actual sedation. A suggested list of equipment and supplies is listed in **Table 6**. Depending on the clinical situation, the provider should modify the list. It is recommended that the equipment be checked just prior to the sedation to ensure it is in working condition.

The child undergoing sedation should be continuously monitored using a pulse oximeter with audible and visible signal

**Table 1** Levels of sedation

Factors	Minimal sedation	Moderate sedation/Analgesia (conscious sedation)	Deep sedation	General anesthesia
Responsiveness	Normal response to verbal stimulation	Purposeful response to verbal or tactile stimulation*	Purposeful response following repeated or painful stimulation*	Unarousable, even with painful stimulus
Airway	Unaffected	No intervention required	Intervention may be required	Intervention often required
Spontaneous ventilation	Unaffected	Adequate	May be inadequate	Frequently inadequate
Cardiovascular function	Unaffected	Usually maintained	Usually maintained	May be impaired

\* Reflex withdrawal from a painful stimulus is NOT considered a purposeful response

from the time sedative agents are administered till complete recovery occurs. Ventilatory adequacy can be monitored by close observation, auscultation or preferably using a continuous nasal capnography. Use of impedance plethysmography to monitor breathing may be unreliable due to its inability to detect early airway obstruction. In situations where direct observation of the child is not possible (i.e. during an MRI scan), continuous capnography is essential to monitor for any apnea or airway obstruction. The pulse oximeter is not a substitute for a robust and independent ventilation monitor. To the extent possible, it is preferable to have the child's face and mouth visible to the observer during the procedure.

Although controversial, it is generally a good practice to administer supplemental oxygen during any deep sedation as it has been shown to reduce the incidence of hypoxemia and bradycardia. However, one should be cognizant that this may delay the detection of an airway obstruction or apnea. Continuous monitoring of heart rate and frequent blood pressure measurements are recommended during moderate and deep sedation. However, use of routine continuous electrocardiography has not been shown to be of any added value. A time-based contemporaneous recording of child's level of consciousness, pulse oximeter reading, capnography, heart rate, respiratory rate and blood pressure should be recorded in a legible manner, preferably on a preformatted documentation flow sheet. These should be recorded at least every 5 minutes during the sedation. In addition, the names of drugs, routes, doses and times of administration should be documented.

Children receiving sedatives are at risk for delayed manifestation of respiratory depression, and can have airway related complications after the procedure is over and no one is closely monitoring the child. This is especially true for oral and rectal routes of administration, where unpredictable absorption can lead to a later than expected peak effect of the drug. Some of the commonly used drug regimens, e.g., chloral hydrate and *lytic cocktail* are notorious for prolonged sedation and are no longer preferred. There should be appropriate level of monitoring of any sedated child recovering from procedure and clearly defined discharge criteria (**Table 7**) should be established.

## ADVERSE OUTCOMES

Many large studies have shown that when performed by appropriately skilled and trained nonanesthesiologists, the incidence of serious adverse outcomes secondary to pediatric procedural sedation are extremely low. The majority of the complications result from respiratory depression or airway obstruction. This could lead to Hypoventilation or hypoxemia, and if not detected and corrected promptly, could lead to serious cardiovascular compromise and neurological injury. A list of usual adverse events seen is given in **Table 8**. An important fact to remember is that all classes of medication and all routes have been associated with adverse outcomes and no provider should be

**Table 2** American Society of Anesthesiologists physical status classification

Class	Status
I	A normal healthy patient
II	A patient with mild systemic disease (no functional limitation)
III	A patient with severe systemic disease (with functional limitation)
IV	A patient with severe systemic disease that is a constant threat to life
V	A moribund patient who is not expected to survive without the operation

**Table 3** Essential elements of premedication history

1.	Any major medical illness affecting the respiratory, cardiovascular, renal or hepatic systems
2.	History of any sedations, anesthesia exposure, surgeries and outcomes
3.	Drug allergies and current medications
4.	History of snoring, sleep apnea or hypoventilation
5.	Last oral intake (nature and timing)
6.	Review of organ systems

**Table 4** Elements of focused physical examination

1.	<i>Vital signs:</i> Heart rate, respiratory rate, pulse oximetry, blood pressure, temperature
2.	Weight
3.	Auscultation of heart and lungs
4.	<i>An evaluation of airways:</i> Facial dysmorphism, retrognathia, micrognathia, trismus, macroglossia, loose teeth, dental appliances, tonsillar hypertrophy, visibility of uvula, short neck, tracheal deviation and obesity.

**Table 5** American Society of Anesthesiologists preprocedure fasting guidelines

Type of food	Fasting period
Clear liquids	2 hours
Breastmilk	4 hours
Light solids	6 hours

complacent about any sedative agent, dose or route. The following factors have been correlated with increased risk of adverse outcomes: multiple sedative agents, inadequate premedication screening and medical evaluation, inadequate/inconsistent

**Table 6** Suggested list of equipment and supplies for pediatric sedation

Emergency medications
Amiodarone
Atropine
Calcium chloride or gluconate
Diphenhydramine
Epinephrine (1:1000, 1:10,000)
Flumazenil
Glucose (50%)
Hydrocortisone, dexamethasone, methylprednisolone
Lidocaine
Naloxone
Salbutamol
Sodium bicarbonate
Vasopressin
Equipment
Adhesive tape
Alcohol wipes
Endotracheal tubes (2.5-, 3.0-, 3.5-, 4.0-, 4.5-, 5.0-, 5.5-, 6.0-, 6.5- and 7.0-mm internal diameter)
Face mask (infant, child, small adult)
Gloves
Hypodermic needles
Intraosseous needle
Intravenous catheters (24-, 22-, 20- and 18-gauge)
Intravenous fluids, including normal saline and lactated ringer solutions
Intravenous tubing and burette drip set
Laryngoscope blades (straight numbers 1, 2 and 3 and curved numbers 2 and 3)
Laryngoscope handles
Oral and nasal airways (pediatric sizes)
Oxygen regulator, flow meter and tubing
Self-inflating or anesthesia bag-valve set (0.5-, 1- and 2-L sizes)
Source of compressed oxygen (e.g., a tank with at least 60 min of supply at high flows or a wall outlet)
Stylets
Suction device (portable or wall outlet)
Suction tubing and canisters
Syringes (1-, 3-, 5- and 10-mL)
Tourniquets
Yankahuer and soft-tip suction catheters (5-, 8-, 10- and 12-F)
Monitors
Capnometer (end-tidal CO <sub>2</sub> monitor) with bi-nasal cannula
Defibrillator with pediatric pads or paddles
Monitor with leads and sensors (respiratory rate, heart rate and ECG)
Pulse oximeter with sensors

**Table 7** Guidelines for discharge of a child recovering from sedation

1. The child should be back to his or her preprocedural mental status and able to be aroused easily.
2. Respiratory and cardiovascular status should be stable, and airway protective reflexes should be intact and airway patent.
3. The child should be able to sit up unaided or should be back to the pre-procedural motor function status.
4. At least 2 hrs should have elapsed since the last administration of any pharmacologic antidote such as flumazenil or naloxone to prevent a re-sedation phenomenon.
5. The child should be discharged with a responsible adult who will accompany the child and be able to understand and react to any postprocedural complications.
6. Written instructions regarding postprocedural diet, activities, precautions, and warning signs and an emergency number should be provided.

**Table 8** Common adverse events during procedural sedation

• Inadequate sedation
• Airway obstruction
• Hypoxemia
• Apnea
• Vomiting
• Hypotension
• Prolonged sedation
• Laryngospasm

physiologic monitoring, lack of independent observer, medication errors and inadequate recovery procedure. In addition, premature infants and infants less than 6 months of age are prone to higher incidence of respiratory depression and apnea. Certain areas like MRI scanner pose unique challenges in terms of monitoring and pose additional risk and require specialized MRI-compatible monitors, devices and infusion pumps.

## SELECTED SEDATIVE AGENTS

There are a large number of sedative and analgesic drugs that can be used to achieve the intended level of sedation and analgesia (**Table 9**). It is generally preferred to use intravenous route for deep sedation. A practitioner should become familiar with a few of the agents and develop a complete understanding of the pharmacokinetics, doses and side effects of the agent being used.

### Chloral Hydrate

Chloral hydrate has been used orally and rectally for many decades. It is an effective sedative agent but provides no analgesia. It has been used extensively in radiology procedures with good results. Traditionally, chloral hydrate is regarded as a very safe agent, and this has often led to complacency on the part of the practitioner in terms of dosing and monitoring principles. The drug can often produce deep levels of sedation and has been associated with adverse outcomes of death and neurologic injury. It has active metabolites including trichloroethanol, which may have a prolonged half-life in younger infants and neonates. Because this drug may lead to a prolonged need for observation after a short radiology procedure, it is not recommended to use chloral hydrate in younger infants who will be discharged home after the procedure.

### Benzodiazepines

Midazolam is the most commonly prescribed drug in this class of agents. It can be administered through oral, intranasal, rectal, intramuscular or intravenous routes. Recently, multiple studies have demonstrated the safety and efficacy of the intranasal route of midazolam administration. It has potent amnesic and anxiolytic properties and is a short-acting sedative. It does not have any analgesic properties and often needs to be combined with topical, local or regional analgesia or systemic analgesia, using narcotic agents or ketamine. The combination of midazolam with an opioid such as fentanyl has been popular but can cause immense respiratory suppression. Respiratory depression caused by midazolam can be reversed by using antagonist flumazenil.

### Barbiturates

Pentobarbital (Nembutal) has been used for many years for sedating children who are undergoing noninvasive radiology procedures. It produces a deep sleep with minimal movement for up to approximately 1 hour and is popular for use during

**Table 9** Suggested dosages and routes for pediatric procedural sedation

Drug	Dose	Onset of action (min)	Duration of action (min)	Common indications	Comments
Chloral hydrate	PO or PR: 25–100 mg/kg, maximal dose 2g	20–30	45–90	Diagnostic radiology procedures in infants and toddlers	Unpredictable effect, paradoxical agitation seen often, prolonged sedation in neonates, may cause emesis
Dexmedetomidine	IV: 1–2 mcg/kg loading dose over 10 minutes, followed by infusion 0.5–2 mcg/kg/h	10–15	10	Diagnostic radiology procedures	Expensive, limited experience, needs infusion pumps, may cause severe bradycardia
Midazolam	IV: 0.05–0.1 mg/kg (maximum of 0.4 mg/kg)	2–5	30–60	For anxiety-producing procedures, bone marrow aspiration, spinal tap with additional analgesia	Excellent amnesia and anxiolysis; combination with fentanyl may produce profound respiratory depression; younger children (5-year) may occasionally need up to 0.6 mg/kg; flumazenil reverses oversedation
	IM: 0.1–0.2 mg/kg	15–20	45–90		
	PO: 0.5 mg/kg	15–30	60–90		
	IN: 0.2–0.6 mg/kg	10–20	30–60		
	PR: 0.3–0.5 mg/kg	15–30	60–90		
Pentobarbital	IV: 1–6 mg/kg total in increments of 1–2 mg/kg	3–5	30–45	Diagnostic radiology procedures including MRI	Excellent hypnotic, although occasionally leads to paradoxical excitement; no analgesic effect; not reversible with antidotes; oral pentobarbital is effective in infants and toddlers
	IM: 1–6 mg/kg (maximum 100 mg)	10–20	45–90		
	PO: 4–6 mg/kg (maximum 100 mg)	20–40	45–90		
Methohexital	PR: 25 mg/kg	10–15	60	Diagnostic radiology procedures	Good immobilization and hypnosis; not reversible
Fentanyl	IV: 1–4 mcg/kg total in increments of 1 mcg/kg	2–3	20–60	Painful procedures	Excellent analgesia; may produce itching (nasal area) and nausea; can cause profound respiratory depression when combined with midazolam; rapid push can cause chest wall rigidity; reversible with naloxone
Ketamine	IV: 1–2 mg/kg loading dose, 0.25–1 mg/kg maintenance q 10–15 minutes	2–5	15–60	Painful procedures, fracture reduction, laceration repair, thoracostomy tube insertion, burn care	Dissociative state, excellent analgesia; can lead to increased bronchial and salivary secretions; produces emergence hallucinations in older (> 10 y) children; contraindicated in children with raised intracranial pressure; effects not reversible
	IM: 2–5 mg/kg	5–10	15–60		
Propofol	IV: 1–1.5 mg/kg loading; 0.25–0.5 mg/kg every 3–5 min; or infusion of 50–150 mg/kg/min	1–2	5–10	Diagnostic radiology procedures, especially MRI; in combination with local/systemic analgesics for painful procedures, e.g., endoscopy	Can rapidly induce state of general anesthesia; apnea on induction seen often; burns in peripheral veins, may be reduced by 1:10 addition of 1% lidocaine; myoclonus seen occasionally; not approved for prolonged sedation in children; not reversible
Flumazenil	IV: 0.02 mg/kg/dose, q 1 min to a maximum of 1 mg	1–2	20–60	Benzodiazepine-induced respiratory depression	Rebound sedation may occur; can precipitate seizures, withdrawal in long-term benzodiazepine users
Naloxone	IV/IM: 0.1 mg/kg/dose, q 1 min to maximum of 2 mg/dose	IV: 1–3 IM: 10–15	20–40	Opioid-induced respiratory depression	Rebound sedation may occur; can precipitate acute withdrawal in long-term opioid users, and one-tenth dose aliquots should be used in them

*These doses are intended only as broad guidelines; each individual patient may have varying needs depending on clinical condition, associated drugs and other confounding factors. It is always a good practice to titrate intravenous drugs slowly to achieve the required effect.*

MRI scanning. Paradoxically, it does cause a small proportion of children, usually in the preschool age, to unpredictably become agitated and dysphoric. Traditionally, pentobarbital has been administered through the intravenous and intramuscular routes; however, more recently, the oral route has been used, and this approach has shown results that are superior to chloral hydrate. Barbiturates do not have any analgesic effects and are unsuitable for sedating children who are undergoing painful procedures.

### Opioids

Opioids such as fentanyl and morphine are commonly used, often in conjunction with a sedative, to achieve analgesia for painful procedures. The fentanyl and midazolam combination is very effective in achieving rapid onset sedation and analgesia, although the combination can result in profound respiratory depression. Fentanyl has been a preferred choice of many practitioners because of its rapid onset of action, shorter duration of effect, lack of histamine release and less cardiovascular depressant action. Respiratory depression, pruritus, nausea and emesis, and hypotension are major side effects of all the agents in this class. Chest wall rigidity is a rare effect from rapid intravenous administration of fentanyl. Naloxone is an effective antidote for the respiratory depression induced by opioids.

### Ketamine

Ketamine is a dissociative anesthetic and produces excellent analgesia, amnesia and sedation for pediatric procedures. It is commonly used in the emergency room setting for fracture reduction and casting, laceration repair and other painful procedures. It is regarded as relatively safer than other sedatives because of its less pronounced depressant effects on respiratory drive and airway protective reflexes. However, it does produce excessive salivation and airway secretions, and there is the risk of aspiration or airway obstruction. It can be administered by intramuscular route with good efficacy. Ketamine has been associated with emergence of dysphoria and hallucinations in adults. However, this phenomenon does not appear to be as prominent in children, and there are recent reports suggesting that no additional benefits are gained by the concurrent use of benzodiazepines.

### Propofol

The use of propofol outside the operating room and by non-anesthesiologists has been steadily increasing over the past few years. There are multiple reports of its efficacy and safety in pediatric procedural sedation. Propofol is a potent ultra-short-acting agent used to induce general anesthesia and is associated with rapid deepening of sedation level to that of general anesthesia. Propofol is a diisopropylphenol. Its actual mechanism of action is unknown, but it is postulated that propofol mediates activity of the gamma aminobutyric acid receptors. All children receiving propofol should be monitored identically to those receiving intravenous general anesthesia, and nasal prong capnography is required.

Propofol has no analgesic property, and topical or local analgesia is needed for painful procedures. It is well suited for brief painful procedures such as spinal taps and bone marrow aspiration in oncology clinics and long nonpainful procedures such as MRI scanning in the radiology department. The short half-life of propofol results in shorter postprocedural recovery time compared with other agents. Propofol often causes a burning

sensation when it is injected in peripheral veins; this effect may be reduced by mixing 1 mL of 1% lidocaine in every 10 mL of propofol and by injecting the drug slowly.

### Dexmedetomidine

Dexmedetomidine is a relatively new drug that has a central alpha 2 agonist activity. Many recent studies have suggested its safety and efficacy. It is particularly useful in radiological procedures. It has rapid onset, short acting with quick and smooth emergence, making it an attractive agent. Although respiratory depression is not common with this agent, severe bradycardia and hypotension is commonly reported. It can produce a paradoxical hypertensive response when given with atropine or glycopyrrolate. The utility of this drug is still being evaluated in the context of procedural sedation.

### IN A NUTSHELL

1. Procedural sedation and analgesia is increasingly required for children for invasive and noninvasive procedures. Pediatricians should be familiar with the principles of safe sedation.
2. Although various levels of sedation are described, a child can lapse into a deeper plane of sedation than intended, and the practitioner should have the ability to recognize and intervene.
3. Appropriate patient selection, focused history and examination are essential for good outcomes.
4. Appropriate equipment and monitoring should be provided for all sedations.
5. Children are at a high risk for prolonged effects of sedatives and postprocedure complication and need to be observed till they are back to baseline state prior to discharge.
6. A variety of agents can be used to achieve the specific goals of immobility, anxiolysis, analgesia, hypnosis and amnesia. The practitioner should be familiar with the pharmacokinetics of the agents he chooses to use.
7. Standard guidelines for fasting should be followed to reduce the risk for aspiration.

# Section 9 POISONING AND ENVENOMATION

**Section Editor** Rakesh Lodha

## Chapter 9.1

### Clinical Approach to a Poisoned Child

P Ramesh Menon

Poisoning is a process of unintentional self-injury, by a xenobiotic exposure through skin and mucosal surfaces, associated with accumulation of toxins in the body due to derangements in the metabolic processes of homeostasis. Identification of the same in a child needs a clinical suspicion, laboratory evaluation and sometimes relevant imaging. Majority are accidental oral exposures at home by toddlers (exploratory ingestion).

Poisoning is a common medical emergency in childhood. In India, accidental poisoning (majority of poisoning in children) has been very frequent below 5 years of age with male dominance. In older children and adolescents, suicide attempts or gestures are more common. From India, there are no community-based data regarding incidence of poisoning. In a retrospective analysis of poisoning from eight regional hospitals in different part of India, pediatric poisonings constituted 0.23–3.3% of the total poisoning. The mortality ranged from 0.64% to 11.6%. Accidental poisoning was common involving 50–90% of children below 5 years of age and males outnumbered the females. Suicidal poisoning was seen after 13 years of age and was due to drugs and household chemicals. Drugs are an important cause of poisoning in children; the drugs consumed usually belong to phenothiazines, antiepileptic and antipyretics. Iron poisoning was seen in younger children. Kerosene was one of the causes of accidental poisoning at all hospitals except Shimla and rural Maharashtra where probably wood charcoal is widely used. Pesticide poisoning was more prevalent in Punjab and West Bengal whereas plant poisoning was very common in Shimla. Significant number of snake envenomation has been recorded from rural Maharashtra. Other less common accidental poisonings in children included alcohol, corrosives, heavy metals, rodenticides, detergents and disinfectants. Thus various regions in the country showed some variation in types and frequency of childhood poisoning which could be attributed to different geographical and socioeconomic background.

#### WHEN TO SUSPECT?

An awareness of the local pattern of poisons (availability/usage) is helpful. A positive history may be available in up to 50%. Any hyperacute onset of (multiple organ) symptoms (in a cluster) and rapid progression in a child are usual clues to poisoning in a child. History of medications or drug availability in house or intake for co-morbid conditions in child or others should be documented as corroborative evidence (even if negative). The index of suspicion should be higher if the child is at risk (age: 1–4 years and/or has a previous history of ingestion).

*Toxidromes* are a cluster of clinical features which often occur together in a patient and may indicate poisoning with specific agents (**Table 1**).

#### WHAT TO SUSPECT?

Pediatric unintentional injuries due to chemical agents are classified as follows:

*Exploratory ingestion* Previously described as accidental ingestion, it signifies a complex interplay of child/substance and environmental factors (injury model). Pica-prone hyperactive victim (1–5 years) with easy access to medicines, cosmetics, detergents or pesticides is the usual clinical situation.

*Child abuse by poisoning* Common in children less than 1 year or more than 5 years, when the history is inconsistent or arouses discomfort. Previous history of poisoning may be available or siblings may have been poisoned; massive overdoses or multiple ingestion; exposure to illicit drugs or alcohol; unusual poisonings with household substances (salt or water, pepper, etc.); other evidence of child abuse or neglect; any of these should lead to the suspicion of abuse. Morbidity of such cases tends to be higher.

*Pediatric medication errors* Due to weight-based dosing (mg/kg dosing) or age-based dosing. Young infants cannot express early symptoms of allergy or adverse reactions. Up to 10% of poisoning deaths are due to these. Multiple pediatric oral suspensions with different concentrations exist such as phenytoin, verapamil, atenolol, tacrolimus and various antibiotics.

*Toxin (Lethal in small doses) ingestion* (**Table 2**) New products (household or medication formulations)

#### HOW TO MANAGE?

Higher body surface area or weight, increased skin perfusion, hydration, greater susceptibility for dehydration and insensible losses are distinct considerations in the management of a young child with poisoning. Increased respiratory rate and minute ventilation deliver a higher dose for airborne toxins by inhalation. Higher risk of respiratory fatigue and failure due to mechanical reasons and physiological sensitivity to hypoxia, metabolic toxins, with a lower reserve (cardiovascular, acid-base, glycogen stores) distinguish children from adults.

Airway patency and protection (ET intubation) should be performed in all children in whom it is threatened. Higher adrenergic tone may result in tachycardia as the lone vital sign abnormality for cardiac output maintenance. Calcium channel blockers (CCBs)/organophosphate (OP) pesticides may precipitate circulatory arrest in very small doses. Hypotension is to be managed with fluids initially. Vasoactive drugs, most commonly dopamine and epinephrine or norepinephrine, are used when hypotension remains fluid unresponsive. Norepinephrine or glucagon is preferred in hypotension due to beta-blocker or tricyclic antidepressants (TCA) induced hypotension. Developmental pharmacodynamics results in enhanced central nervous system

**Table 1** Toxicidromes, mnemonics and examples

Type	AVPU/Mental status	Vitals (Temp/HR/RR/BP)	Pupils	Other manifestations	Examples of toxic agents
Sympathomimetic	Excitation, hallucinations, paranoia	↑↑/↑/↑ wide pulse pressure	Mydriasis	Diaphoresis, tremors, hyper-reflexia, seizures	Cocaine, amphetamines, theophylline, caffeine
Anticholinergic <i>Hot as a hare/dry as a bone/red as a beet/mad as a hatter/blind as a bat/bowel bladder lose their tone and heart runs alone</i>	Excitation, hallucinations, delirium with mumbling speech, coma	↑↑/↑/↑	Mydriasis	Dry flushed skin/mucosa, ileus, urinary retention, myoclonus, choreoathetosis, picking behavior, seizures (rare)	Antihistamines, TCA, antispasmodics, atropine, scopolamine, belladonna alkaloids
Hallucinogenic	Agitation, synesthesia, Hallucinations, depersonalization	↑↑/↑/↑	Mydriasis (usually)	Nystagmus	Phencyclidine, LSD, (e.g., MDMA ["Ecstasy"], MDEA)
Opioid	CNS depression, coma	↓↓/↓↓/↓	Miosis	Hyporeflexia, pulmonary edema, needle marks	Opioids (e.g., heroin, morphine, oxycodone, hydromorphone), diphenoxylate
Sedative-hypnotic	CNS depression, confusion, stupor, coma	↓↓/↓↓/↓	Miosis (usually)	Hyporeflexia	Benzodiazepines, barbiturates, carisoprodol, alcohols, zolpidem
Cholinergic <i>SLUDGE +DUMBELS wheezing/diaphoresis/bronchorrhea/bradycardia/miosis</i>	Confusion, coma	↓↓/↓/↑/↑/↓	Miosis	Salivation, urinary + fecal incontinence, diarrhea, GI cramps, emesis, muscle fasciculations, seizures	Organophosphate and carbamate insecticides, nicotine, pilocarpine, physostigmine, edrophonium
Serotonin syndrome	Confusion, agitation, coma	↑↑/↑/↑	Mydriasis	Tremor, myoclonus, diarrhea hyper-reflexia, clonus, rigidity diaphoresis, flushing, trismus	MAOIs alone or with: SSRIs, meperidine, dextromethorphan, TCAs, L-tryptophan

Abbreviations: AVPU, alert/voice/pain/unresponsive; TCA, tricyclic antidepressant; Temp, temperature; HR, heart rate; RR, respiratory rate; BP, blood pressure.

**Table 2** Small dose toxins, and their major effects

Drug	Lethal effects at	Major effects			
Benzocaine	<20 mg/kg	Seizures	CNS depression	Arrhythmia	Methemoglobinemia,
Calcium antagonists	<40 mg/kg				Bradycardia, hypotension
Camphor	Approximately 50 mg/kg	+	+		Respiratory depression
Chloroquine	<30 mg/kg	+		+	
Diphenoxylate (e.g., Lomotil®)	1.2 mg/kg		+		Respiratory depression
Lindane	Approximately 6 mg/kg	+	+		
Phenothiazines	Approximately 20 mg/kg	+	+	+	
Sulfonyleureas	<1 mg/kg				Hypoglycemia
Theophylline	Approximately 50 mg/kg	+		+	Arrhythmias
Tricyclic antidepressants	Approximately 15 mg/kg	+		+	Hypotension
Toxic alcohols (e.g., methanol, ethylene glycol)	0.3 mL/kg		+		

(CNS) depression with clonidine, codeine, dextromethorphan cough syrups; paradoxical reactions to benzodiazepines and QTc prolongation with sotalol, etc. Neonates require other considerations, e.g., carboxyhemoglobin (COHb) concentrations are higher at 2–5% because carbon monoxide (CO) is a by-product of protoporphyrin metabolism. Neonates are also more susceptible to OP poisoning since their baseline red cell cholinesterase is 50–70% lower.

### EMERGENCY DEPARTMENT: GENERAL LIFE SAVING MEASURES

Stabilization of the ABC immediately is a priority. Screen for occult trauma, ocular and dermal exposures in addition before initiating decontamination. Assess mental status (AVPU), vital signs, pupillary size, skin and look for specific clues (**Tables 1 and 2**).

**A: Airway** (Look for secretions/cough/gag) Caustics/plants containing Calcium oxalate crystals (Philodendron houseplants) have higher airway threat. Intubate the child if there is a (higher) risk of airway compromise.

**B: Breathing** (Look for  $SpO_2$ , breathing pattern) OP poison/cocaine poisoning can sensitize the child to scoline resulting in apnea of up to 7 hours. Try and maintain  $SpO_2$  greater than 95%. Perform a blood gas analysis.

**C: Circulation** (Look for HR, rhythm and blood pressure) Inotropes may worsen cardiovascular toxicity and antiarrhythmics may be proarrhythmic and negatively inotropic. Establish at least two large bore lines in the unstable patient.

**D: CNS depression/excitation** Classify the physiologic status as excited (with increase in temperature, heart rate, blood pressure, respiratory rate); depressed (hypoglycemia, opiate intoxication or thiamine deficiency) or mixed. Hypoxemia, hypoglycemia, opiate intoxication, thiamine deficiency are amongst common causes of altered mental status. Depression of CNS may lead to threat to airway patency.

Do NOT use antipyretics; external or internal cooling measures may be used with muscle relaxants or benzodiazepines. Take samples for serum electrolytes, renal function test (RFT), liver function test (LFT), blood glucose, pH, ECG (**Table 3**). Point of care test (urine, blood, gastric aspirate/vomit) to identify the agent of injury or path of injury are available and should be utilized simultaneously (if not a remote setting). These are nonspecific with respect to the time of exposure to the toxin. Plasma drug levels are not routinely sought except in acetaminophen, salicylate, iron (Fe), lithium (Li), digoxin, theophylline, methanol and anticonvulsants poisonings. The resultant delay in specific management in acute

poisoning is avoidable. A widening of the QRS complex may be the first sign of TCA toxicity.

### MANAGING IN HOSPITAL OR INTENSIVE CARE UNIT

Optimal management of the poisoned child depends upon the specific poison involved, severity of illness and elapsed time between exposure and presentation (**Table 4**). Certain poisons can produce symptoms that mimic common diseases (**Table 5**). Household products (kerosene; insect repellents; pesticides) are the commonest cause of poisoning in children. Medications (drugs) especially anticonvulsants (carbamazepine, phenytoin) and other miscellaneous products including dyes, antiseptics, herbal medicines, button batteries, adhesives are also consumed by children. Consider the maximum amount of substance that could have been ingested by comparing the number of tablets, volume of liquid remaining, details on packaging. When children share a poisonous substance, it is presumed that each child has taken the maximum amount. Supportive care, the mainstay of therapy, variably involves decontamination, antidote therapy, and enhanced elimination techniques. Coupled with decontamination, it is usually sufficient for complete recovery.

#### Decontamination

Decontamination refers to the techniques used to prevent the absorption (in the early stages) of the toxic substance by the body. It is NOT an *always* (to be done) procedure in children.

Emetics and antiemetics are best avoided. Syrup of ipecac is no longer recommended. Gastric lavage is not routinely recommended. It is contraindicated in corrosive ingestion or volatile hydrocarbon poisoning. Adequate airway protection is essential. Gastric lavage is less effective than activated charcoal in reducing the absorption of simulated toxins, but is roughly equivalent in efficacy to ipecac. Gastric lavage in combination with activated charcoal (administered either before lavage or both before and after lavage) is more effective in reducing drug absorption than is activated charcoal given alone, but studies have not confirmed a clinical benefit of gastric lavage. *Activated charcoal has become the preferred method of gastrointestinal decontamination in children.* Voluntary ingestion is preferred to nasogastric administration. It may be ineffective in Fe, Li, bleach, petrochemicals and alcohols (**Table 6**). Specific exposures are dealt in subsequent chapters.

Activated charcoal is an insoluble, nonabsorbable, fine carbon powder made from the burning and crushing of wood, coconut shells, coal and petroleum products, which are then heated with steam, air, or carbon dioxide in the *activation* process, which adds surface area. This enhances the network of inter-connecting

**Table 3** Laboratory clues to diagnosis of poisoning

<i>Lab abnormalities</i>	<i>Chest X-ray</i>	<i>Blood gas</i>	<i>Anion Gap</i>
<b>Rhabdomyolysis</b> Sympathomimetics Anticholinergics Central hallucinogens Neuroleptics (NMS) Malignant hyperthermia Serotonin syndrome Corticosteroids	<b>Irritant gases</b> NH <sub>3</sub> , Cl <sub>2</sub> , H <sub>2</sub> S N <sub>2</sub> oxides Phosgene Smoke SO <sub>2</sub> Metal oxides Acid and alkaline gases Volatile inhalants (hydrocarbons)	<b>Increased osmolal gap</b> (normal 5 ± 7 [SD] mOsm/L) Acetone Ethanol Ethylene glycol Glycerol Hypermagnesemia (>9.5 mEq/L) Isopropyl alcohol Mannitol Methanol	<b>Increased anion gap with metabolic acidosis</b> (>13 mEq/L)* Methanol Ethylene glycol Ethanol Salicylates Isoniazid Cocaine Theophylline
<b>Hepatotoxicity</b> Acetaminophen Ethanol Phenytoin Halogenated hydrocarbons CCl <sub>4</sub> Heavy metals Erythromycin estolate Pyrrolizidine alkaloids (plants)	<b>Radiopaque toxins (CHIPES)</b> C-Chlorinated hydrocarbons (e.g., chloral hydrate, CCl <sub>4</sub> ), Ca salts (e.g., calcium carbonate), Crack vials H-Heavy metals (e.g., Fe, Ar, Hg, Pb, Tl) I-Iodinated compounds (e.g., thyroxine) P-Psychotropics (e.g., phenothiazines, Li, cyclic antidepressants), Packets of drugs (e.g., cocaine and heroin), Play-Doh, K salts E-Enteric-coated tablets (e.g., aspirin) S-Salicylates, Na salts, Sustained-release preparations	<b>Increased oxygen saturation gap</b> (>5% difference) CO, CN SulfHbemia H <sub>2</sub> S MetHb	<b>Decreased anion gap</b> (<6 mEq/L) HyperMg Hypercalcemia Bromide Nitrates Lithium Iodide Spironolactone NH <sub>4</sub> Cl Acetazolamide

**Table 4** Indications for PICU management (few criteria, in intoxicated patients)

Glasgow coma scale $\leq 6$ ; Agitation requiring restraint
$PCO_2 > 45$ mm Hg, hypoxia or respiratory failure (ARDS), and/or endotracheal intubation
$SBP \leq 80$ mm Hg
Metabolic acidosis with $pH \leq 7.2$
Hyperthermia with $T > 104^\circ F$
Poisoning with a "toxic time bomb" - Ingested drug packets, sustained-release preparations
Need for invasive hemodynamic monitoring ; Need for whole bowel irrigation to enhance GI elimination of poison
Need for emergency hemodialysis, hemoperfusion, hemofiltration
Need for emergency antidote which requires close monitoring (e.g., antivenom, Digibind, physostigmine, naloxone drip)
Ischemic chest pain from toxin (e.g., cocaine, carbon monoxide)
TCA or other drug exposure with $QRS > 120$ ms or $QTc > 500$ ms

**Table 5** Toxins that mimic common illnesses

Acute liver failure	Paracetamol	Idiopathic hepatic failure
Hyperthermia, tachypnea, sudden onset	Salicylates	Pneumonia
Hyperglycemia, ketosis, drowsiness	Theophylline	Diabetic ketoacidosis
Non-ketotic hypoglycemia, collapse	Ethanol	Glycogen storage disease

**Table 6** Agents for which activated charcoal is not recommended

Heavy metals: Ar, Pb, Hg, Fe, Zn, Cd
Inorganic ions: Li, Na, Ca, K, Mg, F, I
Boric acid
Corrosives acids, alkali
Hydrocarbons alkanes, alkenes, alkylhalides, aromatic hydrocarbons
Alcohols, acetone, ethyleneglycol, isopropanol, methanol
Essential oils

pores which bind (adsorb) and trap chemicals within minutes of contact, thereby preventing their systemic absorption and toxicity. Activated charcoals (AC) have a binding surface area of 950–2000  $m^2/g$  and can absorb between a few mg and 1 g of intoxicant per gram of activated charcoal. The amount of drug bound by charcoal is dependent upon:

- The characteristics of the ingested substance. Most poisons bind well to AC with the exception of small, highly ionized chemicals such as metals, electrolytes, acids, and alkali;
- The surface area of the specific AC preparation employed; and
- The relative amounts of AC and the intoxicant.

More than 90% of an intoxicant generally is adsorbed when the ratio of AC to intoxicant is 10:1 or greater. Larger doses of activated charcoal, either as single or multiple doses are more effective at preventing drug absorption by mass action. Multiple doses of activated charcoal are used to enhance pre-absorptive and post-absorptive elimination by exploiting the effects of certain drugs that slow gastrointestinal motility (e.g., anticholinergics drugs), interrupting enterohepatic circulation, or "gastrointestinal dialysis." Cathartics (sorbitol) may be administered with the first dose of AC, amongst the multiple doses.

## Enhancing Elimination

Active techniques are restricted to prolonged exposures to high concentrations of toxins. Repeated doses of activated charcoal, where indicated is one such (**Box 1**). It may result in bowel obstruction and perforation).

### BOX 1 Indications for enhancing elimination

Active elimination techniques may be indicated in poisoning with carbamazepine, barbiturates, dapsone, quinine, theophylline, salicylates, Amanita phalloides, slow release preparations, digoxin, phenylbutazone, phenytoin, and piroxicam

*Whole bowel irrigation* is another technique of decontamination for patients who have ingested large amounts of nonabsorbable substances, iron, sustained release preparations and illicit drug packets. It is based on enteral administration of large quantities (30 mL/kg/h) of osmotically balanced polyethylene glycol electrolyte solution to induce a liquid stool. Treatment is continued till rectal effluent clears. This typically takes 4–6 hours. The maximum recommended doses for children older than nine months are 9 months to 6 years: 500 mL/h; 6–12 years: 1000 mL/h; Older than 12 years: 1500–2000 mL/h.

*Forced diuresis*, urinary alkalization or acidification is preferably avoided. Cathartics are also avoided and never used alone for decontamination or enhanced elimination. They are better replaced by Dialysis, hemoperfusion and hemofiltration. Extracorporeal elimination is worthwhile if it increases total body clearance by 30% or more. Substances not amenable to extracorporeal elimination include benzodiazepines, TCA, phenothiazines, chlordiazepoxide and dextropropoxyphene.

## Endoscopy and Surgery

Endoscopic removal should be considered for children who have a life-threatening amount of a substance in the stomach (e.g., bezoars, concretions) that cannot be safely removed by other means. Endoscopy also can be used to remove foreign bodies such as large coins or batteries; however, some of these materials are difficult to grasp with the endoscope and may require surgical removal. Surgical removal also is indicated for plastic packets/pouches because the packets may rupture if endoscopic removal is attempted, and for life-threatening gastric iron bezoars.

## Dilution

Dilution is utilized only for ingestions of corrosive substances such as acids or alkali. The recommended pediatric doses are 120–180 mL of water. Larger doses may induce vomiting. Airway patency must always be assessed before giving fluids by mouth.

## ANTIDOTES

Diagnostic trial of antidotes improved alertness in response to flumazenil for benzodiazepine ingestion; improved alertness in response to glucose for oral hypoglycemic ingestion; physostigmine for anticholinergic agent ingestion (C/I: Wide QRS on ECG); naloxone for opiate ingestion; diphenhydramine for PTZ ingestion. Details are discussed with specific agents or can be obtained from poison centers ([www.who.int/gho/phe/chemical\\_safety/poisons\\_centres/en/index.html](http://www.who.int/gho/phe/chemical_safety/poisons_centres/en/index.html)). Antidotes reverse or reduce poison effects by different mechanisms (**Table 7**).

**Table 7** Examples of antidotes and indication, for uncommon poisons

<i>Antidote</i>	<i>Poisoning indication</i>
Calcium gluconate and calcium chloride (10%) , high-dose insulin euglycemia, IV lipid emulsion	Calcium channel blocker Hydrogen fluoride (HF)
Cyanide antidote kit (may contain sodium nitrite 3%, sodium thiosulfate, + hydroxocobalamin)	Cyanide
Dimercaprol (BAL)	Acute arsenic Inorganic mercury Lead (with encephalopathy)
Ethanol (10%)	Methanol/Ethylene glycol
Fomepizole (4-methylpyrazole)	Methanol Ethylene glycol
Glucagon, norepinephrine infusion	Beta-adrenergic antagonist Calcium channel blocker
Methylene blue	Methemoglobinemia
Propranolol	Thyroxine
Pyridoxine, NaHCO <sub>3</sub>	Isoniazid (INH)
Flumazenil	Benzodiazepines
Na replacement, low dose dopamine	Lithium
Procyclidine	Metoclopramide
Dextrose, octreotide	Sulfonylureas

**IN A NUTSHELL**

1. Evolving homeostatic machinery and developmental shifts places children (including adolescents) at special risk of exposure and risks (exploratory exposure) to injurious agents.
2. Poisoning is a common medical emergency in childhood, in India.
3. Ingestion, ocular and dermal exposures in order of occurrence are the routes of exposure commonly encountered.
4. Activated charcoal and whole bowel irrigation are the only validated decontamination procedures in children (pre-toxic phase).
5. Specific antidotes are available for most (common) pediatric toxins.
6. Outcomes are better with protocol based management in dedicated/ experienced ICUs with close liaison with Poison care centres (e.g : National Poisons Information Centre - +(91)-11-26589391, 26593677; National Health Portal- <http://www.nhp.gov.in> )

## Chapter 9.2

# Poisonings by Common Drugs

Indumathy Santhanam, Sharada Sathish

Young children and infants, unlike adults and adolescents, ingest tablets more out of curiosity with a tendency to orally explore small objects. Unfortunately, even ingestion of one to two tablets can have life-threatening consequences in infants and toddlers. Early recognition, appropriate resuscitation and decontamination is essential to ensure optimal outcomes. Children presenting to the emergency department (ED) with history of tablet ingestion must be evaluated for airway instability, respiratory compromise, bradycardia, tachyarrhythmias, hypotension, convulsions, posturing and pupillary abnormalities within the first minute of arrival. Simultaneously, lifesaving maneuvers are initiated if necessary. Timed documentation of physiological status is mandatory, both for medical management and medico-legal purposes. Even if initially stable, physiological status can rapidly change. Thus frequent monitoring and documentation is essential. The child should be observed at least for 12 hours. If the ABCs are stable, the physician should look for toxidromes or signs that are specific for toxin ingestion.

## RISK ASSESSMENT

History taking, should not delay stabilization of the ABCs. History should include age, sex, approximate time of ingestion (if not witnessed), nature of tablets and whether the ingestion was accidental, suicidal or homicidal. Efforts should be taken to confirm name of the drug by inspecting the original containers, and prescriptions. All potentially accessible medications (purses, pill boxes) of both family members and visitors should be examined. Risk assessment should be based on the *worst case scenario*. It is wise to assume that the time of ingestion was the latest time possible and that all agents that were unaccounted for or missing had been ingested. Though spillage is difficult to estimate, one should presume that all the missing volume was consumed. When more than one child has ingested, then it is assumed that all the children have consumed all the missing drugs. If the ingested drug has been identified, a Poison Control Center (e.g. National Poison Control Centre, All India Institute of Medical Sciences, New Delhi) can be contacted for advice.

The commonest *two pills can kill* list includes, sodium channel blockers such as chloroquine, dextropropoxyphene, propranolol, tricyclic antidepressants, calcium channel blockers, diphenoxylate/atropine, dextropropoxyphene, beta-blockers, sulphonylureas and theophylline slow release (SR). **Table 1** summarizes possible causes of various clinical features.

**Table 1** Drugs and their toxic effects

Cardiac dysrhythmias	Chloroquine Anti-arrhythmic agents Anti-psychotics, anti-depressants
Hypotension and cardiogenic shock	Calcium channel blockers (large doses, sustained release preparations)
Coma	Opioids (direct CNS depression) Sulphonylureas (CNS depression due to drop in blood sugar)
Convulsions	Camphor (excitation)
Metabolic: Hypoglycemia, acidosis	Sulphonylurea, Aspirin

*Toxic effects that occur within a few hours* Chloroquine: Rapid onset of coma, seizures, cardiovascular collapse; Dextropropoxyphene: Ventricular tachycardia; Propranolol: Coma, seizures, ventricular dysarrhythmias, hypoglycemia; Tricyclic antidepressants: Coma, seizures, ventricular tachycardia, hypotension.

*Toxic effects occurring within 8–12 hours* Hypoglycemia occurring within the first 8 hours point towards sulphonylurea toxicity. Slow release formulations take up to 12 hours to start acting. These include the following: Calcium channel blockers (verapamil, diltiazem): Late onset conduction defects, bradycardia, Hypotension and refractory shock; Opioids: Coma, respiratory depression, pin point pupils; Theophylline SR: vomiting, seizures, supraventricular tachycardia.

## INVESTIGATIONS

An urgent glucose estimation is recommended, if a child presents with unknown tablet ingestion. It is also mandatory following ingestion of sulphonylureas and for children presenting with altered mental status. If capillary blood glucose is less than 80 mg/dL, rapid dextrose correction is initiated. If intravenous access is unavailable, intramuscular glucagon (1.0 mg) is recommended. In addition, a 12-lead ECG should be taken for ingestion of cardiac drugs such as digoxin, calcium channel blockers, beta blockers and antiarrhythmic agents. If ECG abnormalities are noted, continuous monitoring is necessary until recovery. If the nature of the ingested drug is unknown, ECG is performed as a screening test. It may be repeated if the child appears unwell or the cardiopulmonary assessment shows instability.

## TREATMENT

### Gastric Decontamination (Table 2)

Gastric lavage and activated charcoal are not routinely performed except in the most severe cases. Since, the potential risks of stomach wash or activated charcoal far outweigh the benefits, decontamination is not recommended.

### Gastric Lavage

Gastric lavage is performed by placing a large bore orogastric tube through which normal saline is administered. The saline is aspirated until the effluent is clear. Though orogastric tubes recover significant amounts of gastric contents, its use is limited due to poor tolerance, stimulation of the gag reflex, risk of aspiration and perforation. The American Academy of Clinical Toxicology (AACT) and European Association of Poison Centres and Clinical Toxicologists (EAPCCT) recommend that gastric lavage may employed, if a large amount of toxin has been ingested and if the patient has been brought within 1h of ingestion.

**Table 2** Drugs used for gastric decontamination

Drug	Dose	Problems during administration	Avoid in the following conditions
Activated Charcoal	1–2 g/kg (max 50–60 g)	Vomiting, Aspiration,	Unprotected airway, Altered mental status
Gastric lavage	10–15 mL/kg	Vomiting, Aspiration	Persistent vomiting
Polyethylene glycol (PEGLEC)	500 mL/h < 5 years 1000 mL/h > 6 years	Vomiting, crampy abdominal pain	GI bleed Intestinal obstruction, ileus Perforation

### Activated Charcoal

Activated charcoal has been used to reduce absorption of a wide variety of toxins from the stomach and the intestinal tract. It acts by interrupting enterohepatic and enteroenteric re-circulation of drugs in the gut lumen. The drugs that can be eliminated are carbamazepine, phenobarbitone, phenytoin, valproate, dapson, theophylline and salicylates. It is difficult to use in children since its lack of palatability and unattractive appearance causes vomiting. The AACT discourages the routine use of activated charcoal except if the ingestion had occurred within 1 hour. The recommended dose of charcoal to drug is 10:1. A dose of 1–2 g/kg is advised if the quantity of the ingested drug is not clear.

### Whole Bowel Irrigation

Polyethylene glycol (PEGLEC) is used for irrigation following ingestion of iron tablets and sustained release medications. It is an electrolyte lavage solution, formulated to prevent extensive absorption or secretion of fluid across the gastrointestinal (GI) mucosa. Large volumes of this solution are administered enterally, until the rectal effluent is clear. The head end is elevated head to at least 45° to prevent aspiration. If emesis occurs, the infusion is discontinued for 30 min, and restarted at half the previous rate and increased as tolerated. Metoclopramide may be given if needed. Whole bowel irrigation (WBI) is safe in children; volumes as large as 44L have been administered without ill effects. Typical rates of administration are 500–1000 mL/h, orally or by nasogastric tube. The adverse effects associated with this procedure consist of vomiting, abdominal cramps and bloating.

### Cathartics

Currently, cathartic agents are contraindicated. The risk of hypernatremic dehydration and cardiovascular collapse is high with sorbitol, while hypermagnesemia is a hazard in children with renal disease.

### Enhanced Elimination

Elimination is not a preferred technique in the management of children presenting with drug ingestion. Theophylline toxicity is the only exception where hemodialysis is recommended. This modality of elimination is employed when clinical evidence of tachyarrhythmias and seizures occur in association with elevated serum theophylline levels.

### Antidotes

Table 3 lists the antidotes for some of the drugs.

### SPECIFIC DRUG INGESTIONS

#### Chloroquine

Chloroquine has a very small toxic-to-therapeutic margin. Fatality has been reported for ingestion of 300 mg of base of chloroquine. Respiratory depression often occurs. Apnea, hypotension, and cardiovascular compromise can occur quickly. Electrocardiographic abnormalities include QRS prolongation, AV block, ST- and T-wave depression, increased U waves, and QTc interval prolongation. Significant hypokalemia may be associated with the cardiac manifestations. Hypokalemia results from chloroquine induced intracellular shifts. Neurologic manifestations include central nervous system (CNS) depression, dizziness, headache, and convulsions. Management is symptomatic. Oro-gastric lavage and activated charcoal are recommended. Enhanced elimination has no role. There is no antidote.

#### Theophylline

Serum levels of 5–15 mcg/mL is considered toxic. Toxic effects are due to adenosine antagonism, release of endogenous norepinephrine resulting in adrenergic receptor stimulation and phosphodiesterase inhibition. Toxicity affects the GI, cardiovascular, CNS, musculoskeletal system. It also causes

**Table 3** Antidotes for common drug poisoning

Poison/overdose	Antidote	Route	Dosage	Adverse effects
Paracetamol	N-Acetyl Cysteine	IV	150 mg/kg over 1 hour followed by 50 mg/kg over 4 hours followed by 100 mg /kg over 16 hours	Nausea, vomiting
		PO	140 mg/kg loading followed by 70 mg/kg Q4h for 17 doses	Anaphylactoid reactions
Benzodiazepines	Flumazenil	IV	0.2 mg over 30s; if response inadequate repeat q1 min to 1 mg max	Nausea, vomiting, facial flushing, agitation, headache, dizziness and seizures
Beta blocs	Glucagon	IV	0.15 mg/kg bolus followed by infusion of 0.05–0.15 mg/kg/h	Hyperglycemia, nausea and vomiting
Calcium channel blockers	Insulin	IV	1 U/kg bolus followed by infusion of 0.5–1 U/kg/h	Hypoglycemia, follow serum potassium and glucose closely
	Calcium	IV	Dose depends on the specific calcium salts*	
Iron	Deferoxamine	IV	Infusion of 5–15 mg/kg/h; maximum 6 g/24 h	Hypotension(minimized by avoiding rapid infusion rates)
Isoniazid	Pyridoxine	IV	Empirical dosing-70 mg/kg; maximum 5 g If intake dose is known 1 mg per milligram of INH	Can be given by NG tube and IM also
Sulfonylureas	Octreotide	IV/SC	1–2 mcg/kg/dose (adults: 50–100 mcg) q6-8h	
Antihistamines/ Anti-cholinergics	Physostigmine	IV/IM	0.02 mg/kg over 5 min may repeat q5-10 min to 2 mg max	Bradycardia, asystole, seizures, bronchospasm, vomiting, headache

\*: Calcium chloride- 100 mg/mL (10%): 20 mg/kg/dose not to exceed 45–90 mg/kg/h with a maximum concentration of 20 mg/mL  
Calcium gluconate- 200–500 mg/kg IV or PO

metabolic derangements. Intractable vomiting, ventricular extrasystoles, tachyarrhythmias, peripheral vasodilation, hypotension, hyperventilation, respiratory alkalosis, respiratory failure and acute lung injury may be precipitated. CNS toxicity is characterized by headache, anxiety, agitation, insomnia, tremor, irritability, hallucinations, and seizures. Hypokalemia can also occur. Fluids and vasopressors are given for hypotension and beta blockers are used to control arrhythmias. Benzodiazepines (BDZ) and barbiturates are recommended for convulsions. Hypokalemia is corrected if identified. Ondansetron is useful for vomiting. There is no role for orogastric lavage since absorption is rapid. However, activated charcoal plays an important role. Whole bowel irrigation helps in elimination of sustained release formulations. Hemodialysis is indicated for serum theophylline level more than 90 µg/mL or serum level more than 40 µg/mL and seizures/hypotension unresponsive to intravenous fluid/ventricular dysrhythmias.

### Iron Toxicity

Ferrous salts have a propensity to cause more toxicity than the nonionic iron preparations. Toxicity occurs when more than 20 mg/kg of elemental iron is ingested. Direct mucosal irritation can cause GI bleeding. Ingestion of a large quantity of iron tends to overwhelm the normal storage sites and proteins. Since iron takes part in redox reactions, free iron, leads to generation of a large amount of free oxygen radicals. Oxidative damage of the various organs results in congestion, edema, necrosis, and hemorrhage. Iron being an intracellular poison affects almost every organ in the body. It can cause acute periportal hepatic necrosis, pancreatic necrosis, and pulmonary and renal damage.

The free iron ions in circulation also disrupt the mitochondrial oxidative phosphorylation leading to generation of excessive H<sup>+</sup> ions leading to metabolic acidosis. Furthermore, iron also causes massive postarteriolar dilatation, increased capillary permeability and coagulopathy leading to shock, within the first few hours after ingestion. Myocardial failure, caused by reactive oxygen species induced myocardial damage further contributes to shock. Clinical features are summarized in **Table 4**.

### Laboratory Parameters

Laboratory values including chemistries, hemoglobin, iron concentration, coagulation, and hepatic profiles are necessary in the sickest patients. An arterial blood gas, venous blood

**Table 4** Clinical stages in iron intoxication

Stages	Time	Manifestation	Remarks
Stage I Local toxic stage	0–6 hours	Nausea, vomiting, abdominal pain, and diarrhea, hematochezia melena and hematemesis	Absence of vomiting excludes serious toxicity
Stage II Latent stage	6–24 hours	Resolution of previous symptoms	Ongoing cellular damage
Stage III Shock stage	12–24 hours	Shock, lethargy, seizures coma	May occur in first few hours following massive ingestion
Stage IV	2–3 days	Hepatic failure	Uptake of iron by the reticuloendothelial cells of liver
Stage V	2–8 weeks	Gastric outlet obstruction	Rarely seen

gas, or stat electrolytes rapidly detects a metabolic acidosis. Anion gap metabolic acidosis, elevated leukocyte counts more than 15000/mm<sup>3</sup> and hyperglycemia greater than 150 mg/dL suggest iron intoxication. Toxic ingestion is characterized by peak concentrations of iron at 2–6 hours after ingestion. Serum iron concentrations between 300 µg/dL and 500 µg/dL usually correlate with significant GI toxicity and modest systemic toxicity. Concentrations between 500 µg/dL and 1000 µg/dL are associated with pronounced systemic toxicity and shock. Concentrations more than 1000 µg/dL is associated with significant morbidity and mortality. Lower concentrations cannot exclude the possibility of serious toxicity.

### Management

Stabilization of airway breathing and circulation takes the priority. Large bore intravenous access should be established while decontamination procedures are started simultaneously. Fluid resuscitation should take place along with WBI. History should include time of since ingestion and the percentage of elemental iron in the preparation and how much of iron per kg body weight had been ingested. Consumption of iron more than 30 mg/kg warrants admission and investigation (**Table 5**).

**Table 5** A triage based on alleged amount of consumption of elemental iron

Dose	Risk for toxicity	Procedure
<20 mg/kg	Little risk	Decontaminate Observation for 6 hours
20–60 mg/kg	Moderate risk	Decontaminate Observe for 6 hours consider desferrioxamine chelation
>60 mg/kg	High risk	Decontaminate Start chelation therapy

**Gastrointestinal decontamination** Activated charcoal does not bind iron and hence should not be used for decontamination. Gastric lavage may be employed. Endoscopic removal is an alternative strategy for removal of large ingestions.

**Enhance elimination** Whole bowel irrigation is the preferred method for iron ingestion. The usual dose of WBI with polyethylene glycol electrolyte lavage solution is 500 mL/h in children. This rate is best achieved by starting slowly and increasing as tolerated, often using a nasogastric tube and an infusion pump to administer large volumes. Antiemetics such as metoclopramide or serotonin antagonists can be used to treat nausea and vomiting. Irrigation must be continued until abdominal films are clear.

### Antidote

The specific antidote for iron toxicity is deferoxamine. In the presence of ferric iron (Fe<sup>3+</sup>), deferoxamine forms the complex ferrioxamine, which is excreted by the kidneys, imparting a reddish-brown color to the urine (vin rosé). Deferoxamine chelates only the free iron and not the iron present in transferrin, hemoglobin, or hemosiderin. 100 mg of deferoxamine mesylate chelates approximately 8.5 mg ferric iron. Intravenous administration of deferoxamine should be considered in patients with persistent vomiting, toxic appearance, lethargy, signs of shock, hypotension and metabolic acidosis. Deferoxamine administration also should be considered for any patient with a serum iron concentration more than 500 µg/dL. In patients manifesting serious signs and symptoms of iron poisoning, deferoxamine should be initiated as an intravenous infusion, starting slowly and gradually increasing to a dose of 15 mg/kg/h (maximum daily dose 360 mg/kg, and total 6 g). Hypotension is the rate-limiting factor as more rapid infusions

are used. Infusions are continued until the urine returns to normal color. Occasionally, normal urine color in presence of high serum iron has been reported making the decision regarding the end point difficult. Stable clinical state of the patient combined with urine color in response to deferoxamine, and serum iron less than 100 µg/dL is probably the more appropriate end-point.

### Antihistamine and Cough Medication Toxicity

Sympathomimetic agents are also major ingredients of cough preparations. Severe toxicity is characterized by hypertension, reflex bradycardia, arrhythmias, convulsions and coma. Paracetamol is the next major ingredient and should not be overlooked when evaluating toxicity. Opioids are also commonly found in cough syrups. Dextromethorphan, another common drug in cough mixtures, has low toxic potential. Codeine, another common ingredient causes toxicity when large amounts are ingested. Anti-histamines in cough syrups may cause CNS depression and cardiovascular toxicity. The presence of several active ingredients in a single preparation may produce a confusing clinical picture and potentiate adverse effects. A variety of arrhythmias can occur due to blockade of the sodium channel.

### Management

Seizures are controlled using benzodiazepines. Hypotension should be corrected with fluids and inotropes. Adrenaline should be avoided since paradoxical hypotension has been noted. Asymptomatic children should be observed for a minimum of 4 hours. Multiple dose activated charcoal can be administered since anticholinergic agents decrease GI motility.

Physostigmine (0.02 mg/kg slowly IV over 3–5 min) is the recommended antidote for treating anti-cholinergic toxicity. Magnesium sulphate may be administered in arrhythmias due to terfenadine and astemizole.

### Paracetamol Poisoning

When toxic dose of paracetamol has been ingested, absorption occurs within 2 hours and peak plasma levels are attained within 4 hours.

**Phase 1: 30 min–24 hours after overdose** During this phase children demonstrate malaise, anorexia, nausea, vomiting, pallor, and diaphoresis. Rarely, following massive overdoses resulting in direct toxic effect on the liver, metabolic acidosis and coma could occur.

**Phase 2: 24–72 hours after overdose** The phase 1 symptoms subside. Right upper quadrant tenderness develops due to hepatic damage. Liver enzymes and INR (International Normalized Ratio) are elevated. Renal functions begin to deteriorate, although blood urea remains normal secondary to decreased hepatic urea formation.

**Phase 3: 72–96 hours after overdose** In this phase, on-going hepatic centrilobular necrosis progress to fulminant hepatic failure. The clinical features reflect this process resulting in coagulation defects, hypoglycemia, metabolic acidosis, and jaundice. Renal and cardiac failures, along with hepatic encephalopathy lead to death.

**Phase 4: 4 days–2 weeks after overdose** If the victim survives phase 3, complete resolution of hepatic and renal function is possible.

### Risk Assessment

The clinician must attempt to predict the likely clinical course and potential complications following ingestion. History should focus on the dose and concentration of paracetamol ingested and whether there is history suggestive of increased susceptibility to toxicity. Examination and investigations should be aimed at recognizing evidence of liver damage (**Table 6**). Clinical or biochemical evidence of liver injury may not be apparent for up to 24 hours after acute paracetamol overdose. Serum paracetamol

**Table 6** Paracetamol dosing that may be associated with hepatic injury\*

	Adults and children >6 years	Children aged 0–6 years
Acute single ingestion	>200 mg/kg or 10 g whichever is less over a period of less than 8 hours	≥200 mg/kg over a period of less than 8 hours
Repeated supra therapeutic ingestion	>200 mg/kg or 10 g (whichever is less) over a single 24 hours period >150 mg/kg or 6 g (whichever is less) per 24 hours period for the preceding 48 hours. >100 mg/kg or 4 g/day (whichever is less) in patients with predisposing risk factors**	>200 mg/kg over a single 24 hours period >150 mg/24 hours period for the preceding 48 hours >100 mg/kg/24 hours period for the preceding 72 hours period in patients with predisposing risk factors**

\* Adapted from Dart RC, Erdman AR, Olson KR et al. Acetaminophen poisoning; and evidence-based consensus guidelines for out of hospital management. Clin Toxicol. Philadelphia: 2006;44:1–18.

\*\* predisposing risk factors are use of enzyme inducing drugs, malnutrition, prolonged fasting

levels should be used to assess the need for *N*-acetylcysteine (NAC) administration in all patients with deliberate paracetamol self-poisoning, regardless of the stated dose. The best surrogate marker indicating the potential for injury is a timed serum paracetamol level plotted on a nomogram. However, the nomogram cannot be applied for repeated or staggered doses, or if the time of ingestion cannot be determined with confidence.

The most important risk factor for liver damage and death after acute paracetamol ingestion is the extent of delay beyond 8 hours until treatment with NAC commences. Treatment within 8 hours will prevent all serious hepatic injury. However, NAC has frequent adverse effects, is moderately expensive and requires hospitalization, so it is not reasonable to administer it to every patient with possible paracetamol overdose.

The treatment nomogram (available from Daly FF1, Fountain JS, Murray L, et al. *Med J Aust.* 2008;188:296–301) is to simplify decision making. This provides both a margin of safety for patients who may possess risk factors and a small margin of error for estimation of time of ingestion, and avoids the need for potentially confusing additional lines.

### Management

Gastric lavage or induction of emesis is not useful. A single dose activated charcoal may be administered at a dose of 1 g/kg mixed into a slurry with water or juice if the ingestion has occurred within 2 hours, more than 200 mg/kg ingestion or the toxic dose has been ingested in tablet form. Specific antidote is *N*-acetylcysteine. NAC, when administered within 8 hours of ingestion can prevent fatality. Beyond 8–10 hours of ingestion, efficacy decreases. Risk assessment for patients presenting within 8 hours can be plotted on a nomogram when they present with known time of ingestion along with serum paracetamol levels. For those who present beyond 8 hours after ingestion, NAC should be commenced immediately if the dose exceeds the threshold for possible toxicity or the patient shows clinical signs suggestive of paracetamol toxicity (nausea, vomiting, right upper quadrant pain or tenderness). Evaluation of serum paracetamol and alanine aminotransferase (ALT) levels should also be performed as soon as possible. If serum paracetamol level is subsequently found to be below the nomogram line, *N*-acetyl cysteine may be stopped; if above the line, it should be continued.

The baseline serum ALT level helps to evaluate level of risk and provides useful baseline data if NAC is indicated. Additionally, when NAC is commenced, baseline international normalised ratio and platelet count provide data regarding severity of hepatic failure. *If the time of ingestion is unknown*, or the treating clinician is not confident of the history of ingestion, it is safest to treat the patient as a delayed presentation. NAC infusion appears to preserve cerebral blood flow and perfusion better than traditional therapies such as mannitol and hyperventilation. With the exception of established liver failure, where the intravenous route has been investigated, intravenous and oral NAC administration is equally efficacious in treating paracetamol toxicity. Oral NAC has fewer severe side effects than IV NAC. Discontinuation of NAC is based on reduction of serum paracetamol level to  $<10$  mcg/mL and the absence or resolution of liver injury. Once these conditions can be assured, discontinuation of NAC therapy is appropriate. Outcomes following use of the 20-hour, 48-hour and 36-hour IV NAC dosing protocols and other short-course dosing protocols suggest that all therapies are safe and effective the patients are treated within 8 hours of an acute ingestion. **Flow chart 1** summarizes the management of paracetamol poisoning.

### Salicylate Poisoning

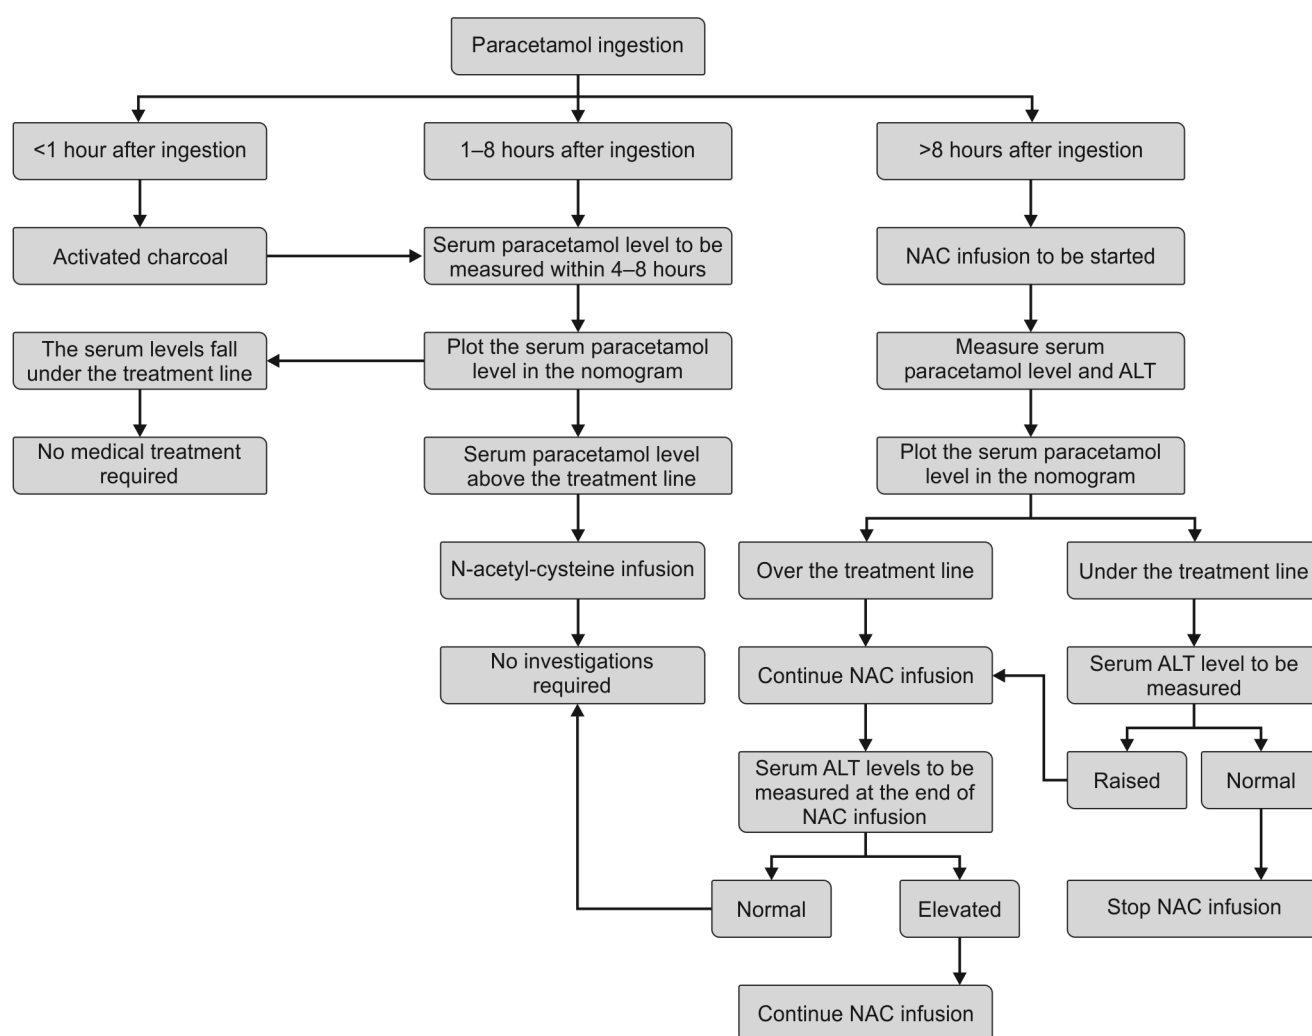

In addition to ingestion of acetyl salicylic acid (aspirin), salicylate poisoning may also result from application of salicylate containing

ointments, keratolytic agents, or other agents containing methyl salicylate (oil of wintergreen). Liniments and ingredients used in hot vaporizers contain high concentrations of methyl salicylate (up to 30% in liniments and 100% oil of wintergreen). The intentional or unintentional ingestion of such topicals is usually disastrous: approximately 1–2 teaspoons (5–10 mL) of methyl salicylate can be lethal for a young child. Onset of symptoms usually occurs within 2 hours of ingestion. In a child, weighing 10 kg, the minimum toxic salicylate dose of approximately 150 mg/kg body weight. One milliliter of oil of wintergreen contains 140 mg/kg of salicylate.

### Clinical Features (Box 1)

Salicylates stimulate the respiratory center in the brainstem, leading to hyperventilation and respiratory alkalosis. CNS effects may include vertigo, hyperactivity, agitation, delirium, hallucinations, convulsions, lethargy, and stupor. Coma is rare and generally occurs only after massive ingestions (serum salicylate concentrations  $>100$  mg/dL) or mixed overdoses. In addition, salicylates are weak acids and in toxic concentrations replace 2–3 mEq/L of plasma bicarbonate. Impaired renal function resulting from salicylate toxicity leads to accumulation of sulfuric and phosphoric acids. The latter interferes with the Krebs cycle limiting the production of adenosine triphosphate (ATP). Uncoupling of oxidative phosphorylation, causes accumulation of pyruvic and lactic acids and generates large amounts of heat. Salicylate induced increased

**Flow chart 1** Algorithm for acute paracetamol poisoning with known time of ingestion

**BOX 1 Features of Salicylate Poisoning**

**Coagulation abnormalities:** Hypoprothrombinemia, inhibition of factors V, VII, X, platelet dysfunction.

**Gastrointestinal:** Nausea, vomiting, hemorrhagic gastritis, decreased motility, pylorospasm.

**Hepatic:** Abnormal liver enzymes, altered glucose metabolism.

**Metabolic:** Diaphoresis, hyperthermia, hypoglycemia, hyperglycemia, hypoglycorrhachia, ketonemia, ketonuria.

**Pulmonary:** Tachypnea, respiratory alkalosis, acute lung injury.

**Renal:** Tubular damage, proteinuria, sodium and water retention, hypouricemia.

fatty acid metabolism generates ketone bodies: beta-hydroxybutyric acid, acetoacetic acid, and acetone. The net result is a wide anion gap metabolic acidosis. A significant component of this metabolic acidosis is a ketoacidosis. The pH of salicylic acid offers a unique opportunity to increase elimination by alkalinizing the urine.

### Treatment

The rapid cardiopulmonary cerebral assessment is performed. Fluid losses following salicylate poisoning can be huge, especially in children, and can be attributed to tachypnea, vomiting, fever, a hypermetabolic state, hyperpnea, and insensible perspiration. Shock or dehydration must be adequately assessed and corrected if necessary, along with any glucose and electrolyte abnormalities. Multiple dose of activated charcoal may help. Forced alkaline diuresis helps rapidly remove salicylates. Hemodialysis may be needed in severe toxicity.

### Nonsteroidal Anti-inflammatory Drugs (NSAIDs)

The commonest NSAIDs used for children are ibuprofen, mefenamic acid and diclofenac. Most of the acute toxicity due to NSAIDs is due to inhibition of COX 1 enzyme in the GIT. This inhibits the formation of cytoprotective prostaglandins PGE<sub>2</sub> and PGI<sub>2</sub> resulting in decreased production of mucus and bicarbonate, promotes HCl secretion, decreases gastric blood flow. All these lead to reduced GI protection. The acidosis associated with NSAID overdose occurs infrequently and usually is a high-anion-gap metabolic acidosis. The most common effects of toxicity are due to GI distress and CNS depression. Other CNS effects may include changes in cognition, hallucinations, muscle twitching, or seizures and are most frequent after mefenamic acid overdose. Children who ingested more than 400 mg/kg are more likely to develop seizures, apnea, hypotension, bradycardia, metabolic acidosis, and renal and hepatic dysfunction.

### Management

The cardiopulmonary cerebral assessment should be performed to determine the physiological status. If the physiological status is unstable, resuscitate the ABCDs. Benzodiazepines are necessary for control of seizures following large dose consumption of mefenamic acid. Acid base status should be evaluated and managed. Fluid and electrolyte imbalances are corrected. Proton pump inhibitors are administered to treat or prevent GI toxicity. As the absorption of NSAIDs is very rapid, gastric lavage is not indicated. Children who have consumed more than 100 mg/kg of ibuprofen and more than 25 mg/kg of mefenamic acid should receive activated charcoal. Hemodialysis is ineffective. There is no specific antidote.

### Isoniazid (INH) Poisoning

INH is rapidly absorbed via GI tract (GIT) and attains peak concentrations within 2 hours. INH alters the metabolism of pyridoxine, creating a functional deficiency of pyridoxine that

results in impaired activity of pyridoxine-dependent enzyme systems, as well as a decrease in catecholamine synthesis. INH also interferes with the synthesis of gamma-aminobutyric acid (GABA), an inhibitory neurotransmitter. Acute intoxication of INH leads to a triad of refractory seizures, hyperglycemia and metabolic acidosis. The clinical features appear within 30 min of ingestion. Seizures occur following ingestion of 20 mg/kg of INH and persist until GABA is regenerated. Protracted coma (24–48 hours) occurs following seizures. Metabolic acidosis occurs due to increased lactic acid levels.

### Management

Gastric lavage is performed and activated charcoal is administered if ingestion of drug has occurred within an hour. Asymptomatic patients who present to the ED within 2 hours of ingestion may be observed for a 6 hours period for signs of toxicity. There is no role for increased elimination. If comatose or convulsing, the airway is secured and ventilation is provided. If shock is identified, small volume aliquots are administered. If convulsing, standard protocol for status epilepticus is started. Benzodiazepines complement the action of pyridoxine in the control of seizures and are the drugs of choice. As phenytoin has intrinsic GABA-ergic activity they are contraindicated. Gastric lavage is withheld until airway is stabilized. Pyridoxine (1 g per 1 g of INH) is the antidote of choice. In children, if unknown quantities have been ingested 70 mg/kg of pyridoxine to a maximum of 5 g may be administered at a rate of 1 g every 2–3 min.

### Benzodiazepines

Benzodiazepines (BDZ) are the most common sedative hypnotics prescribed and used. Intentional poisoning is more common in adolescents. BDZ overdose by itself is safe in children, but when it is taken in combination with other drugs, may result in depressed level of consciousness. Combination of drugs with BDZ is more toxic due to their synergistic effects and cause more CNS depression.

### Clinical Features

Significant overdoses manifest as slurred speech, ataxia, and incoordination. Moderate to severe toxicity manifests as stupor or coma. In the most severe cases, all neurologic responses may be lost and respiratory depression parallels CNS depression. Hypoventilation produces respiratory acidosis and contributes to cardiovascular depression. The vast majority of children develop symptoms within 4 hours of BDZ ingestion. 90% of the children develop ataxia, as the most common sign of toxicity. Only 10% children develop respiratory depression.

### Management

Gastric lavage may be performed if the ingestion has occurred within the past 1 hour. Activated charcoal has a doubtful role. Flumazenil rapidly reverses the sedative effects of BDZ. Flumazenil's onset of action is within 1–3 min. Its maximum effect lasts for 6–10 min. Dosage: 0.01 mg/kg (maximum dose: 0.2 mg) with repeated doses of 0.01 mg/kg given every minute to a maximum cumulative dose of 1 mg. It is administered rapidly IV injection over 15–20 in a large IV line. Care is taken not to exceed 0.2 mg/minute.

### Phenytoin Poisoning

Clinical features include nausea, vomiting, dizziness, vertigo, lethargy, weakness, cardiac arrhythmias, abdominal distention or ileus, and renal failure. Acute overdose predominantly causes neurotoxicity affecting cerebellar and vestibular functions. CNS drug levels correlate with serum drug levels: serum phenytoin levels

>15 mg/dL: nystagmus; >30 mg/dL: ataxia; >50 mg/dL: lethargy, slurred speech, pyramidal and extrapyramidal manifestations.

### Management

If the child is stable, serum phenytoin levels are evaluated. The therapeutic serum drug levels are 10–20 mg/mL. Gastric lavage is performed within the first hour of ingestion. Multidose activated charcoal is indicated, to prevent drug absorption. However, there is no role for increased elimination and no specific antidote is available. Deaths from phenytoin toxicity are rare.

### Beta-Blockers

Beta-blockers are rapidly absorbed from the GIT with their peak effect ranging from 1 hour to 4 hours. Toxicity results in blunting of the chronotropic and dromotropic response. There is interference in the uptake of calcium into the sinus node leading to stimulation of calcium-sensitive outward potassium channels and subsequent refractory bradycardia. Toxicity also results in centrally mediated respiratory depression, the mechanism of which is unknown. Other clinical features include hypotension, unconsciousness, hypoglycemia and seizures. Propranolol is the commonest agent associated with fatality.

### Management

If the physiological status is stable, decontamination using activated charcoal is advised. If ingestion had occurred less than an hour ago, gastric lavage may be performed. If sustained release tablets had been ingested PEGLEC should be considered. If bradycardia is noted, in addition to the steps taken above, injection atropine is advised. Glucagon is the antidote of choice (start with 50 mcg/kg IV, increase to maximum 10 mg till a response occurs at 1–2 min intervals). Then a glucagon infusion is started at the response dose/hour. Calcium infusion is initiated. Supportive management is given for shock. Supra-physiological doses of vasopressors may be needed, if shock is refractory to fluids.

### Calcium Channel Blockers

Diltiazem and verapamil are the most toxic of calcium channel blockers (CCB). They inhibit the L-type calcium channels leading to reduction in the myocardial calcium flux, decreased force of contraction, and bradycardia. Decrease in the vascular smooth muscle calcium influx leads to vasodilatation. Toxic doses can lead to hyperglycemia. Toxicity features appear within 2–3 hours of the ingestion (delayed up to 6–8 hours in sustained release CCBs). If child presents with bradycardia, hypotension or cardiogenic shock, provide ventilation, small aliquots for shock resuscitation and early inotropes, if needed. Orogastric lavage and WBI is advised. Therapy is symptomatic. There is no specific antidote.

### Anti-diabetics and Hypoglycemics

Sulfonylureas act by binding to the potassium ATP channels and inhibiting the potassium efflux stimulated insulin release. Biguanides inhibit gluconeogenesis. Clinical features are due to hypoglycemia mediated CNS symptoms. Single dose activated charcoal may be useful in children with metformin overdose. Gastric lavage has a doubtful role. Therapy focuses on maintenance of euglycemia by ensuring oral feeds or administration of dextrose

infusion. Despite dextrose infusion, if hypoglycemia persists, octreotide is administered at 4–5 µ/kg/day SC divided in 6 hourly doses. If blood glucose (BG) is greater than 60 mg/dL and the child is asymptomatic, observation is recommended for at least 8 hours. Hemodialysis may help in children with severe metabolic acidosis due to metformin ingestion.

### IN A NUTSHELL

1. The “two pills can kill” list includes, sodium channel blockers such as chloroquine, dextropropoxyphene, propranolol, tri-cyclic anti-depressants, calcium channel blockers, diphenoxylate/atropine, dextropropoxyphene, beta-blockers, sulphonylureas and theophylline SR.
2. Paracetamol dose less than 150 mg/kg does not warrant further action.
3. Ideally, N-acetylcysteine (NAC), should be administered within 8 hours of ingestion of paracetamol to prevent fatality. Beyond 8–10 hours of ingestion, its efficacy decreases.
4. The intentional or unintentional ingestion of topical agents having methyl salicylate as ingredient is usually disastrous. Approximately, 1–2 teaspoons (5–10 mL) of methyl Salicylate can be lethal for a young child.
5. Gastric decontamination such as gastric lavage and activated charcoal are not routinely performed in asymptomatic children with normal cardiopulmonary cerebral assessment unless a large quantity has been ingested and the presentation is within 1 hour.
6. Dextrostix and ECG should be performed as part of screening for unknown toxicity and repeated as needed.
7. Activated charcoal is useful for drugs such as carbamazepine, phenobarbital, phenytoin, valproate, dapsone, theophylline and salicylates.
8. Polyethylene glycol (PEGLEC) is useful in ingestion of iron tablets and sustained release medications.

## Chapter 9.3

# Hydrocarbon Poisoning

Jayashree M, Karthi N

Hydrocarbon ingestions account for about 5% of all accidental poisonings and 25% of all fatal ingestions in the under-5 children, globally. The hydrocarbon compounds commonly implicated in toxic exposures are as depicted in **Table 1**. Accidental kerosene poisoning remains a serious problem in India and other developing countries with incidence varying from 25% to 60%. In a recent study from India, kerosene ingestion accounted for 27% of all poisoning admissions to pediatric intensive care unit (PICU) though a decreased incidence has been noted in the recent 5 years. Data from USA for hydrocarbon related injuries in the past decade has also shown a decline from 19.5 ED to 13.8 ED visits per 100,000. Despite the declining trend, hydrocarbons still present a high-risk for injury in children younger than 5 years. The accessibility depends on factors such as demography, socioeconomic status, education, local belief and customs. Hydrocarbons especially kerosene is commonly used as fuel for cooking and lighting in rural homes. Inappropriate storage in unmarked soft drink or beverage bottles and attractive color (blue color additive) coupled with children's desire to explore, account for the high incidence of hydrocarbon exposures. Higher incidence during summer months is because the kerosene stored in soft drink bottles is mistakenly consumed for water by the thirsty children. The morbidity and mortality associated with hydrocarbon ingestion are related to pulmonary aspiration and its complications.

## HYDROCARBON COMPOUNDS

Hydrocarbons are broadly classified into aliphatic (straight chain) and aromatic (with a benzene ring) hydrocarbons. The former derived as byproducts of petroleum distillation are the most commonly implicated hydrocarbons in toxic exposures. The potential for pulmonary aspiration depends primarily on the triad of viscosity, volatility and surface tension. Compounds with low viscosity (flow easily), high volatility (aids pulmonary absorption) and low surface tension (allows the substance to spread easily over the contacted surface) carry the highest risk for aspiration. Of the three, the most important determinant for pulmonary aspiration is the viscosity as it facilitates entry and deeper penetration. Substances with viscosity less than 45–60 SSU (Saybolt seconds

universal) are considered at high-risk for aspiration. There is no correlation between volume of hydrocarbon ingested and severity of aspiration. Kerosene has a bad taste which precludes large volume ingestions. Ingestion of even small amounts poses a risk of serious pulmonary toxicity especially in young children. Although vomiting often precedes and precipitates aspiration, lack of vomiting does not rule out the possibility of aspiration. Gastrointestinal absorption is minimal and systemic toxicity is rare even with ingestion of large doses (12–18 mL/kg).

*Halogenated hydrocarbons* are used in households and industries as solvents, dry-cleaners, degreasers and vehicles for paints and varnishes. They are highly volatile (ability to vaporize) and toxic exposures occur mainly by inhalation. Intentional inhalation can be encountered in adolescents when taken for recreational purposes. Halogenated hydrocarbons also possess high aspiration potential, but differ from aliphatic agents in their ready absorbability from GI tract and increased potential to produce systemic toxicity of CNS, cardiac, hepatic and renal systems. *Aromatic hydrocarbons* are a less frequent cause for childhood poisoning and their exposure occur primarily in occupational settings. Intentional inhalation abuse may be seen in older children. Pulmonary and CNS manifestations predominate in acute toxicity.

It is however important to remember that a mixture of different hydrocarbons may be present in the exposed product and is often difficult to isolate the unique effects of a single substance. Many insecticides, metals and other toxic chemicals may be contained in a petroleum vehicle making it very important to identify every ingredient within a commercial product before treatment.

## Pathophysiology

The key pathophysiological feature of hydrocarbon toxicity is surfactant destruction which causes alveolar collapse, ventilation-perfusion mismatch and hypoxemia. As the illness progresses, capillary damage and increased permeability lead to diffuse hemorrhagic alveolitis, finally culminating into a chemical pneumonitis. The changes in lungs are similar irrespective of the type of aliphatic hydrocarbon aspirated. Highly viscous hydrocarbons tend to produce a more localized and indolent lipid pneumonia. CNS manifestations, if any, in kerosene poisoning are due to hypoxia and acidosis resulting from pulmonary toxicity rather than due to direct effects. Direct CNS toxicity however is a feature of halogenated and aromatic compounds. The damage to the nerve cell membrane may be brief or permanent depending on the duration of exposure. Fatty infiltration of liver and centrilobular necrosis are observed with halogenated hydrocarbons.

## Clinical Features

More than 90% of the symptoms of hydrocarbon ingestion are related to the respiratory tract. Initial symptoms include coughing, choking and gasping, far more pronounced in large volume ingestions. These then progress to tachypnea, retractions and cyanosis suggestive of aspiration pneumonia. The time from ingestion to onset of respiratory distress is usually about 30 min, peaking over 48 hours and resolving in the next 2–8 days with supportive care. The pungent odor of kerosene may be apparent in the breath. Wheeze and crackles may be heard on auscultation. Fever is common, early in the course due to direct tissue inflammation. However, persistence of fever beyond 2 days suggests bacterial superinfection. CNS symptoms with aliphatic agents are generally secondary to pulmonary involvement and limited to mild irritability, drowsiness and rarely seizures. On the other hand, halogenated compounds produce dose related direct CNS toxicity. An initial excitatory phase is often followed by CNS

depression, resulting in stupor and coma. Life-threatening cardiac arrhythmias can occur early in the course. Hepatic and renal dysfunction may develop after 2–4 days.

### Investigations

All symptomatic children with suspected aspiration should have a chest radiograph. Maximum radiographic changes can occur from 2 hours to 72 hours after hydrocarbon exposure. Since chest X-ray findings correlate poorly with clinical symptoms, initial radiographs may be normal and in less severely ill, waiting for 4–6 hours before obtaining a chest radiograph may yield more information. The radiographic findings range from unilateral to bilateral lower lobe densities to large areas of consolidation and atelectasis (**Fig. 1**). Pleural effusions and air leaks are uncommon (**Fig. 2**).

Arterial blood gas analysis is indicated in all children with respiratory distress to detect hypoxemia and/or hypercarbia. Leukocytosis can occur even in the absence of infection. In symptomatic patients and those who have ingested toxic additives, laboratory evaluation should include blood count, electrolytes,

**Figure 1** Chest X-ray showing bilateral infiltrates

**Figure 2** Chest X-ray showing bilateral infiltrates and right side pneumothorax [intercostal drainage (ICD) tube in situ]

and liver and renal function tests. Toxicological analysis for hydrocarbons has no value in clinical management.

### Treatment

#### Decontamination

Management of hydrocarbon ingestion is primarily supportive. The main objective is to prevent aspiration. Gastric decontamination is not recommended as these compounds have poor GI absorption. Moreover lavage or induced vomiting increases the risk of aspiration. In cases where lavage has to be done, for e.g., in ingestions that are large volume, multiple toxins or toxins with potential for systemic toxicity like halogenated or aromatic compounds, pesticides, metals camphor, etc., it should be done with a cuffed endotracheal tube in situ. Skin exposure should be treated with removal of contaminated clothes and irrigation with soap and water. Administration of activated charcoal may induce emesis and hence not indicated.

#### Respiratory Support

All children with respiratory symptoms should be treated with supplemental oxygen and vital signs and oxygen saturation monitored. Continuous positive airway pressure may be needed in some children to maintain oxygenation. The need for intubation and ventilatory assistance should be based on clinical assessment and findings on arterial blood gas analysis. The principles of ventilation are the same as for any other parenchymal disease. Chest radiographs may be obtained to identify atelectasis or air leaks. Bronchospasm can be treated with aerosolized beta-2 agonists. Fluid balance should be carefully monitored.

Corticosteroids and prophylactic antibiotics are not recommended due to lack of evidence. Exogenous surfactant administration for acute respiratory distress syndrome due to hydrocarbon pneumonia is of unproven benefit. Successful use of high frequency ventilation and extracorporeal membrane oxygenation has been reported in refractory cases.

### Outcome

Most patients recover fully with supportive care. Mortality has ranged from 1% to 5% in most series. Hypoxemia at admission, prior lavage, need for ventilation and secondary infections have been shown to be predictors of poor outcome. A small percentage of survivors were noted to have minor pulmonary function abnormalities, pneumatoceles and pulmonary fibrosis during follow-up.

### Disposition

In emergency department, children should be observed for at least 6 hours. Children who remain asymptomatic or those who are mildly symptomatic but become asymptomatic during the period of observation can be safely sent home with a follow-up advice. All patients with worsening symptoms, signs of toxicity (hypoxia, altered mental status), markedly abnormal chest radiograph, presence of toxic additives and suicidal intent should be admitted.

### Prevention

Parental education and counseling regarding proper storage with regulatory restraints on packaging and availability of hydrocarbon products are of paramount importance in protecting children from further episodes of exposure.

**IN A NUTSHELL**

1. Accidental hydrocarbon ingestion, especially kerosene is a significant problem in children.
2. Inappropriate storage, being mistaken for water are chief causes for poisoning, especially in a rural setup.
3. Aliphatic hydrocarbons are mostly implicated in toxic exposures. Triad of viscosity, volatility and surface tension determine the risk of aspiration.
4. Pulmonary manifestations predominate. No correlation between volume of ingestion and severity of aspiration.
5. Hydrocarbons have poor GI absorption. Features of systemic toxicity are largely secondary to hypoxia and acidosis.
6. Management is supportive and mainly to prevent aspiration.
7. Lavage is contraindicated as it tends to worsen severity of aspiration.
8. Corticosteroids and prophylactic antibiotics have no role.
9. Most patients recover fully with supportive care.
10. Hypoxemia at admission, prior lavage, need for ventilation and secondary infections have been shown to predict poor outcome.

## Chapter 9.4

# Poisoning in the Household

Narayanan P, Harikrishnan KN

Household poisoning and other injuries are among the foremost causes of child mortality in India. Most of the poisoning exposures occur in children aged 5 years or younger. This could be attributed to the explorative nature of toddlers, along with curiosity, increasing mobility, and a tendency to put things in their mouths. Instances of pediatric poisoning generally are unintentional (> 99.0% of all poisoning exposures). More than 80% of poisoning exposures occur in the home, the environment in which children of this age spend most of their time.

The common household poisons include agents used for cleaning, plant poisons and those used for destruction of pests or insects (**Table 1**). Many of these act as mild skin and mucosal irritants and exposure to them may be asymptomatic or mildly symptomatic. They usually resolve spontaneously with supportive treatment. However, few among them, particularly pesticides and certain plant poisons may cause life threatening manifestations.

A major part of this chapter is devoted to poisoning with organophosphorus compounds as they are one of the commonest, yet deadly, poisons being dealt with in the pediatric emergency; the second half is devoted to other poisons like plant poisons, phosphorous, naphthalene, etc., some of which may be lethal.

**Table 1** Common household products of low toxicity

Floor cleaner	Bath oil
Toilet cleaner	Silica gel
Laundry blue (washing blue)	Deodorant
Soap	Emulsion paint
Shampoo	Glue (PVA and superglue)
Conditioner	Hair treatments
Bleach	Make up and skin care
Air freshener	Plant care
Baby oil	Polish

## EPIDEMIOLOGY

An analysis of poisoning cases reported to the National Poisons Information Centre, AIIMS, New Delhi revealed that the highest incidence of poisoning was due to household agents (44.1%), followed by drugs (18.8%), agricultural pesticides (12.8%), industrial chemicals (8.9%), animals bites and stings (4.7%), plants (1.7%) and others. Data from south India identified agrochemical pesticides as the most important agent of acute poisoning (49% of cases) followed by drugs (17%). The common predisposing factors responsible for children getting poisoned in the household are highlighted in **Box 1**.

### BOX 1 Predisposing factors for poisoning in the household

- Easy availability of hazardous substances.
- Attractive color, smell and packaging of poisons.
- Storage of such materials in tins/bottles, which previously contained edible items.
- Poor knowledge among parents regarding child-resistant packaging and toxicity of various substances.
- Failure of safe disposal of leftover pesticides after use.

## ORGANOPHOSPHATE AND CARBAMATE POISONING

Organophosphates and carbamates are responsible for an estimated 200,000 deaths in rural Asia annually. According to hospital-based pediatric data on poisoning from India, pesticides constitute a significant proportion of causes ranging from 10% to 56%. The common pesticides reported in poisoning include organophosphates, carbamates, and pyrethroids.

## Pathophysiology

Organophosphates and carbamates are lipid soluble agents. Hence, they are well absorbed through the skin, mucous membranes, gastrointestinal tract and also by inhalation. Since they do not produce any local irritation, substantial exposure can happen undetected through these routes. Once absorbed, they rapidly bind to the enzyme, acetylcholinesterase, found in all cholinergic nerve endings and in red blood cells (RBCs). While carbamates bind reversibly to the enzyme, the phosphorylation of acetylcholinesterase by organophosphate compounds can become irreversible with time (aging). The time taken for aging can vary from few minutes in the case of certain nerve gases to many days for some commercially available pesticides. Oximes are antidotes which can only regenerate acetylcholinesterase that has not aged. Therefore, the effectiveness of oximes may be as short as few hours to as much as days depending on the compound involved.

Inhibition of acetylcholinesterase leads to the accumulation of acetylcholine, thus leading to hyper-stimulation of acetylcholine receptors. This results in the clinical features of cholinergic over activity at the muscarinic and nicotinic receptors and also in the central nervous system (CNS). The nicotinic receptors are primarily distributed in the autonomic ganglia and neuromuscular junctions of skeletal muscles while muscarinic receptors are distributed in the visceral organs, secretory glands and smooth muscles (**Table 2**). The symptoms produced reflect the location of these receptors.

Prolonged excessive stimulation of nicotinic receptors can lead to temporary downregulation and insensitivity to acetylcholine. This temporary insensitivity of varying severity which develops after 24–48 hours after exposure to organophosphates could be the possible explanation for development of the *intermediate syndrome* in organophosphate poisoning; this is seen between the early cholinergic symptoms and the late onset polyneuropathy (see section on clinical features). In addition, inhibition and aging of neuropathy target esterase (different from acetylcholinesterase) is postulated to be the cause of late onset organophosphate induced delayed polyneuropathy (OPIDP), seen more commonly in adults.

## Clinical Features

The clinical spectrum of organophosphate poisoning encompasses three temporarily separated clinical syndromes:

1. The acute cholinergic phase
2. The intermediate syndrome
3. Organophosphate induced delayed polyneuropathy

The first two are life threatening while OPIDP is a disabling disease rarely seen in children. The clinical presentation of organophosphate poisoning can be a challenging diagnosis, as there may not be any history of exposure from the care givers. Moreover, sometimes the offending agent could be a mixture of different compounds (e.g., organophosphate and pyrethroids or organochlorine products) or may contain organic solvents (kerosene, ethanol, ethylene glycol, etc.) which might alter the clinical presentation. However, in most instances, the characteristic constellation of symptoms (*cholinergic toxidrome* as it is known in toxicology) is highly suggestive and relatively easy to

**Table 2** Distribution of muscarinic and nicotinic receptors

Peripheral nervous system			Neuroendocrine system	Central nervous system (CNS)
Autonomic ganglia		Neuromuscular junction (skeletal muscle)	Parasympathetic peripheral junctions (smooth muscles, secretory glands, etc.)	Adrenal medulla
Sympathetic	Parasympathetic	Nicotinic	Muscarinic	Nicotinic
Nicotinic	Nicotinic			

recognize (**Table 3**). The muscarinic [diarrhea, urination, miosis, bradycardia, bronchospasms, emesis, lacrimation, lethargy, salivations, sweating (DUMB BELLS)], nicotinic [mydriasis, tachycardia, weakness, hypertension and fasciculations (MTWHFS)] and CNS features can occur in any combination; the predominant manifestations can vary from patient to patient and also in a given patient during the course of the illness. Practically, the most useful clinical features during routine management are salivation (**Fig. 1**), decreased air entry into the lungs due to bronchorrhea and bronchospasm, constricted pupils, excessive sweating, bradycardia, and hypotension.

The intermediate syndrome can occur in up to 20% of patients with organophosphate poisoning. Though the classical presentation occurs 2–4 days after the exposure, usually once the acute cholinergic crisis is abating, it can occur as early as 12–16 hours also. The classical features are weakness of the neck (neck flop) and proximal muscles of the limbs, progressing to involvement of respiratory muscles resulting in respiratory paralysis. The weakness is lower motor neuron type with flaccidity and diminished reflexes and recovers completely in a week's time with supportive therapy alone.

**Table 3** Signs and symptoms of organophosphate poisoning (cholinergic toxidrome)

Muscarinic	Nicotinic		Both Muscarinic and nicotinic (central nervous system)
Parasympathetic system	Sympathetic system	Neuromuscular junction	
Diarrhea	Mydriasis	Weakness	Confusion
Urination	Tachycardia	Fasciculation	Convulsions
Miosis	Hypertension, hyperglycemia		Coma
Bradycardia, bronchorrhea, bronchospasm	Sweating		
Emesis			
Lacrimation, low blood pressure			
Salivation, secretion, sweating			

**Figure 1** Excessive salivation in a child with organophosphate poisoning

## Differential Diagnosis

In the absence of a definite history of exposure, sometimes the diagnosis can be challenging especially if the clinical presentation is not classical. It should be noted that all pesticides are not organophosphates or carbamates and unless typical cholinergic toxidrome is present, an alternate agent should be suspected. The common differential diagnoses that are considered are encephalitis, CNS infections, kerosene aspiration, organochlorine or pyrethroid poisoning, and status epilepticus. Children with acute heart failure due to myocarditis or scorpion sting can have lung signs (frothing, wheeze) and autonomic features (sweating, tachycardia, hypotension, etc.) which can mimic organophosphate poisoning.

## Approach to Diagnosis

The only laboratory test used in clinical practice for confirmation of the diagnosis is RBC and plasma cholinesterase levels. In addition to nerve endings, cholinesterase is also present in RBCs (acetylcholinesterase) and also in plasma (butyrylcholinesterase, also known as pseudocholinesterase). Since organophosphate

compounds can inhibit these cholinesterases also to varying extent, low levels of these enzymes can indicate exposure to organophosphates. Though they are helpful in confirming the diagnosis, treatment should not be delayed for want of test results. Butyryl cholinesterase levels recover by 7% per day, once the organophosphate is completely eliminated; and may be used for monitoring of therapy.

## Management

The general principles of management are resuscitation at admission, administration of oxygen, blocking the muscarinic effects by administering atropine, regeneration of acetylcholinesterase with the help of oximes and mechanical ventilation for respiratory failure (**Box 2**). Even though there is some controversy regarding the efficacy of oximes, WHO still recommends their use in this setting. Rapid intravenous administration of pralidoxime can produce laryngospasm, muscle rigidity, neuromuscular blockade and paralysis. Hence, it should be administered as an initial loading dose over 5–10 min followed by continuous infusion. If the exact agent is not known and the patient has the classical cholinergic

**BOX 2 Treatment of organophosphate poisoning**

- Check airway, breathing, and circulation. Place patient in the left lateral position, provide oxygen, if available. Intubate if necessary to maintain airway and breathing.
- Administer 0.01–0.04 mg/kg of atropine (minimum 0.1 mg) as a bolus intravenously. Will need higher initial doses in most instances. Start an infusion of isotonic fluids to maintain normal blood pressure and urine output above 0.5 mL/kg/h.
- Record pulse rate, blood pressure, pupil size, presence of sweat, and auscultatory findings at time of first atropine dose.
- Give pralidoxime chloride 20–40 mg/kg intravenously over 20–30 min; followed by an infusion of pralidoxime 5–10 mg/kg/h.
- After 5 min of giving atropine, check pulse, blood pressure, pupil size, sweat, and chest sounds. If no improvement, give double the initial dose of atropine.
- Monitor every 5 min; administer double dose of atropine if no response. Once signs of improvement are present, stop dose doubling. Tachycardia is not a contraindication to atropine since it can be caused by multiple factors. The pupils will usually dilate; however, this sign is not a useful endpoint for initial atropine treatment because a delay exists before maximum effect. However, very dilated pupils are an indicator of atropine toxicity.
- Once the child is stable, start atropine infusion hourly at 10–20% of the total dose required to reverse the muscarinic effects. Monitor hourly to see the degree of atropinization. If dose is less, cholinergic features will reappear. In that case repeat bolus doses of atropine as above and increase the infusion rate. If child becomes agitated and febrile with absent bowel sounds and urinary retention, suspect atropine overdose. Immediately stop the infusion and wait 30–60 min for these features to settle before starting again at a lower infusion rate.
- Continue the oxime infusion until atropine has not been needed for 12–24 hours.
- Assess strength of neck flexors regularly in conscious children by asking them to lift their head off the bed and hold it in that position. Any sign of weakness indicates that the child is at risk of developing peripheral respiratory failure (intermediate syndrome).
- If the child is agitated, review the dose of atropine infusion and provide adequate sedation with diazepam. Physical restraint of agitated patients can result in severe hyperthermia due to the combined effects of atropine (lack of sweating), agitation and warm weather conditions. Hence adequate sedation is important.
- Look for recurring cholinergic crises due to release of fat soluble organophosphorus from fat stores. This can occur for several days to weeks after ingestion of some organophosphorus compounds. These patients will need retreatment with atropine and oxime.

toxidrome, a therapeutic trial with oximes is justified. Gastric lavage is controversial and should be considered only if the child is brought immediately after exposure. Thorough decontamination of skin, mucous membranes and clothing are required in most cases; especially if ingestion was not the primary route of exposure.

Newer modalities of treatments target decreasing the synthesis and release of acetylcholine (magnesium sulfate, clonidine) and removing the organophosphate from blood by hemodialysis or hemofiltration. Scavenging the organophosphate by administration of butyrylcholinesterase and recombinant bacterial phosphotriesterases, or hydrolases also have been tried. These therapies do not have sufficient evidence at present to recommend for routine use.

In most children with organophosphate poisoning, rapid reversal of cholinergic toxidrome is possible within an hour of presentation and the atropine and oxime infusion can be tapered over the next 24–48 hours. A few patients may require ventilator support for a short duration especially if they have prominent CNS manifestations or have suffered prolonged hypoxia. Children who develop intermediate syndrome might require mechanical ventilation for 3–7 days or longer. Oximes and atropine are not effective in treating this condition, which can develop as early as 12–16 hours after exposure.

**Prognosis**

The reported mortality of organophosphate poisoning varies from 15% to 30%. Survival depends not only on the type of organophosphate involved and the delay in initiating therapy, but also on the availability of supportive therapy like mechanical ventilation. The various factors related to the organophosphate compound which affects prognosis are the toxicity, presence of impurities, formulation, need for activation in the body, speed of binding to acetylcholinesterase and aging and the duration of action.

**RODENTICIDE POISONING**

Rodenticides may have many toxic ingredients. The older rodenticides were based on coumarin like compounds which resembled warfarin in its action, leading to coagulopathy and death of rats. Zinc and aluminum phosphide are also commonly used in rodenticides. Aluminum phosphide is commonly known as Celphos<sup>®</sup>, Quickphos<sup>®</sup> and Phostoxin<sup>®</sup> and is available as sealed metal tubes containing pellets. Because of the frequent use, rats are now resistant to such compounds, and hence alternatives are being used, the commonest and highly toxic being yellow phosphorous.

Ratol paste, which contains 3% yellow phosphorous is, nowadays, commonly available and can be rapidly fatal. Elemental phosphorous exists as the red phosphorous, which is nonvolatile, insoluble and nonabsorbable and white or yellow phosphorous which can cause systemic side effects. Yellow phosphorous is a local and systemic toxin causing severe damage to gastrointestinal, hepatic, cardiovascular and renal systems. It is used as rodenticide and in fireworks. Modes of exposure include direct ingestion and absorption through skin, mucous membranes, and inhalational route. It is distributed to all tissues, but around 70% is concentrated in the liver, peak levels being reached 2–3 hours after exposure.

**Pathophysiology**

Phosphorous is a protoplasmic poison. It inhibits oxidative phosphorylation resulting in cellular hypoxia. Phosphine gas (PH<sub>3</sub>), which is released when phosphorous (zinc/aluminum phosphide) comes in contact with gastric hydrochloric acid, also increases oxidative stress by induction of free radicals and inhibition of catalase. The hypoxic insult affects all organs, particularly the liver, heart, kidneys and brain, resulting in multiorgan dysfunction and death. The fatal dose is 1–5 mg/kg; death may occur as early as 24 hours or as late as 6–7 days after exposure.

**Clinical Features**

Clinical features of yellow phosphorous poisoning can be divided into three characteristic phases:

The *first phase* manifests with local effects on the gastrointestinal mucosa and lasts less than 24 hours. Children may be asymptomatic or may complain of burning epigastric pain, vomiting, intense thirst and rarely, diarrhea. Stools are often dark and luminous, often referred to as smoking stool syndrome.

The *second phase* lasts up to 3 days (24–72 hours) postexposure and patients are characteristically asymptomatic. This may give a false impression that there is no significant toxicity and lead to a premature discharge from hospital. However, extreme caution should be exercised, as most patients with significant amount of ingestion will have a catastrophic course of events. Children may have minor gastrointestinal symptoms. Vascular collapse and myocardial dysfunction leading to cardiogenic shock, although rare, can complicate these phases.

The *third phase* is characterized by reappearance of the primary symptoms. Jaundice, often with pruritus and other features of hepatic failure, including bleeding manifestations appear. There may be abdominal distension and worsening sensorium, which heralds the onset of hepatic encephalopathy.

Children may manifest with features of shock because of poor intake, ongoing bleed or myocardial damage. Other neurological manifestations include headache, tremor, impaired vision, cramps, paralysis and coma. Myocardial involvement manifests with hypotension, arrhythmias (including bundle branch blocks, conduction blocks, extrasystoles and repolarization abnormalities) and cardiogenic shock. Echocardiography reveals transient global hypokinesia. Temporary bone marrow suppression, isolated cholestasis and even pulmonary edema have been reported. Acute tubular necrosis leading to acute kidney injury may be seen in more than 50% cases. Liver biopsy shows features of toxic hepatitis with extensive necrosis, ballooning degeneration and steatosis. The causes of death include hepatic and renal insufficiency and cardiogenic shock.

### Management

Ratol (yellow phosphorous) ingestion has a high mortality rate of 27–73% in various case series, which is directly related to the ingested dose. The absence of a specific antidote and lack of good supportive therapies in hepatic failure contribute to the high mortality. Early elevations in transaminases or alkaline phosphatase, more than tenfold rise in alanine aminotransferase, severe derangement in prothrombin time (INR > 6), metabolic acidosis and presence of hypoglycemia signify poor prognosis.

Mainstay of therapy is supportive management and measures to remove as much unabsorbed poison as possible. Caution should be exercised in the emergency room as spontaneous combustion and explosion while attempting RT passage has been reported. Gastric lavage with potassium permanganate to convert phosphorous to harmless oxides is recommended. Patients should be carefully monitored for hepatic encephalopathy and acute kidney injury. It is reasonable to give vitamin K and fresh plasma transfusions in case of spontaneous bleeding. Supportive therapy for hepatic failure, including high carbohydrate, low fat diet, fluids, antibiotics, lactulose should be given. Studies have not shown any clear benefit from steroids, exchange transfusion or N-acetylcysteine (NAC). Liver transplantation should be considered as a lifesaving procedure. However, the prohibitive cost and involvement of other organs are significant limitations, and mortality remains high.

There are recent reports of improved survival following use of NAC as an adjuvant, when patient presented early (mortality 14.3% in NAC group compared to 66% in non-NAC group) to the ER. Magnesium sulfate, because of its membrane stabilizing action may be used intravenously to prevent cardiac conduction abnormalities.

### Prevention of Pesticides and Rodenticide Poisoning

Since most of the instances of pediatric poisoning are accidental in our country, health education regarding safe storage and disposal of these compounds can bring down the occurrence of these unfortunate accidents. Better regulation regarding packaging and sale of existing compounds and also development of pesticides which are safer and nontoxic to humans may be long-term strategies to address this preventable cause of mortality and morbidity in our country.

## PLANT POISONS AND MUSHROOMS

### Oleander Poisoning

Oleander is a common shrub found in South Asia (**Fig. 2**), the common members being white oleander (*Nerium oleander*) and yellow (*Thevetia peruviana*) oleander. Although all parts of the plant are poisonous, the fruits and seeds are responsible for most of the poisoning reported. It is used as an abortifacient and as components of rodenticides or insecticides. Exposure may be

**Figure 2** Pink oleander plant with flowers

accidental or suicidal ingestion of parts of the plant or by inhalation of fumes from the burning leaves.

### Pathophysiology

Cardiac glycosides or cardenolides are the toxins responsible for the characteristic manifestations of oleander poisoning. The cardenolides present in common oleander include oleandrin, digitoxigenin, nerrin, folinerin and rosangenin and those in yellow oleander include thevetin A and B, thevetoxin, peruvoside, ruvoside and neriifolin. These compounds contain a steroid nucleus with a lactone ring, which strongly resembles digitoxin. This structural similarity is responsible for the inhibition of Na-K ATPase enzyme system. This causes conduction block across SA and AV node, and is also responsible for hyperkalemia and intracellular calcium accumulation which leads to ventricular arrhythmias. Other mechanisms of toxicity include activation of sodium channels causing prolonged depolarization and impaired repolarization. Oleandrin is responsible for local irritation of mucosa. The fatal dose is one leaf or one seed and death may occur within 6 days.

### Clinical Features

Oleander poisoning manifests with predominant gastrointestinal and cardiac symptoms. Nausea, vomiting, diarrhea and mucosal erythema develop within an hour. Perioral paresthesias, dizziness, progressive skeletal muscle weakness and excessive salivation have been reported. Cardiac manifestations include hypotension, bradycardia and arrhythmias. Presence of unexplained bradycardia in the presence of heart failure is a paradoxical feature which can make the treating physician suspect oleander poisoning. In a recent observational study, the commonly reported arrhythmias include sinus bradycardia, sinus arrest or exit block, second-degree AV block followed by third-degree heart block and rarely supraventricular arrhythmias and first-degree heart block. ECG was normal in 40% of patients. Ventricular ectopics and ventricular tachycardias are uncommon in contrast to digoxin toxicity.

Metabolic abnormalities documented include hyperkalemia, hypokalemia and hypomagnesemia. The degree of hyperkalemia correlated with the serum digoxin cross reactive cardiac glycoside concentration and with cardiac arrhythmias.

### Management

Children suspected to have ingested oleander should be monitored for at least 12–24 hours because there can be a latent period before manifesting symptoms. Any symptomatic patient

should be admitted for intensive monitoring, preferably in the intensive care unit. Multi-dose activated charcoal (MDAC) is said to decrease absorption of glycosides and also interrupt enterohepatic circulation; however, there is substantial difference between two recent randomized controlled trials on the efficacy of MDAC in oleander poisoning. Hypotension may be managed by appropriate fluids or vasopressor agents. Bradycardia usually responds transiently to atropine (0.02–0.05 mg/kg/dose IV) which may be repeated based on the response. However, temporary pacemakers are required in majority of patients with conduction blocks and persistent bradycardia. Arrhythmias usually resolve within 24 hours, but rarely may persist up to 3–6 days. Indications for temporary pacemakers include complete heart block, Mobitz type II second-degree block, sinus bradycardia with heart rate less than 40/min and sinus arrest with pauses more than 2 sec.

Antidigoxin Fab antibodies were found to significantly reverse arrhythmias early leading to an increase in the heart rate and correction of hyperkalemia. The therapeutic response usually occurs in an hour and sinus rhythm is restored in more than 70% cases in a couple of hours. The dose is 400–800 mg in 200 mL saline IV as an infusion over 20 min under close monitoring. Unfortunately, the exorbitant cost limits its use in developing countries like India.

Rapid correction of electrolyte abnormalities is also important in decreasing mortality. Isoprenaline, magnesium sulfate, phenytoin and recently fructose-1,6-diphosphate are other treatment modalities which have been tried, though there is no substantial evidence to support their routine use.

### Datura Poisoning

Datura, belonging to Solanaceae family is a common plant found all over India (**Fig. 3**). The fruits and seeds are the most toxic, though ingestion of any plant part can cause symptoms. It is misused as a stupefying poison mainly for criminal purposes and as components of home remedies by quacks. Exposure is most commonly by accidental ingestion of fruits.

### Pathophysiology

Datura contains daturine, which is a mixture of alkaloids—hyoscyne, levo-hyoscyamine and traces of atropine. These alkaloids when absorbed after ingestion antagonize the muscarinic effects of acetylcholine. Nicotinic receptors are unaffected. The chief sites of action are cholinergic muscarinic receptors of postganglionic parasympathetic nerves and cortical and subcortical levels in the brain. The fatal dose is approximately half a teaspoon of datura seeds; death may occur within 24 hours.

**Figure 3** Datura fruit

### Clinical Features

Following ingestion, children manifest with excessive thirst, blurring of vision, confusion, agitation and difficulty in swallowing. Tachycardia is a consistent sign, the absence of which should incite a search for an alternate diagnosis. Other signs include dry mucous membranes, flushing of skin, fever or hyperpyrexia, dilated pupils, urinary retention and sluggish bowel sounds. The typical features may be summarized by the famous statement “*hot as a hare, blind as a bat, dry as a bone, red as a beet and mad as a wet hen*”. The neurological features due to central anticholinergic effect include disorientation, ataxia, visual incoordination and visual or auditory hallucinations. The initial restlessness and confusion may progress to stupor and coma within 2–4 hours and may prove fatal. Transient hypertension, arrhythmias and seizures have been described.

### Management

Children who are asymptomatic and those without central anticholinergic effects usually recover spontaneously, and need only observation for around 24 hours. Children with severe poisoning should be admitted. Intensive neurological monitoring and care of airways and breathing is required, especially in comatose patients. Hyperpyrexia responds to tepid sponging and antipyretics. Seizures should be managed with anticonvulsants like diazepam. Children may be very agitated and violent and usually do not respond well to hypnotics. Physostigmine, an acetylcholinesterase inhibitor is the specific antidote. It can cross blood brain barrier, and reverses both central and peripheral antimuscarinic effects of *datura*. It is indicated when child presents with seizures, hallucinations and supraventricular tachycardia. Dose is 0.5 mg IV slowly over a period of 3–5 min, and may be repeated every 10 min (maximum dose 2 mg).

### Mushroom Poisoning

There are many species of mushrooms available, which can lead to varied clinical manifestations, when ingested. *Amanita phalloides* is the worst offender, which can lead to acute hepatic failure. The major classes of mushrooms with their predominant mechanism of toxicity are listed in **Table 4**.

## HOUSEHOLD PRODUCTS OF LOW TOXICITY

### General Household Cleaning Products

Household cleaning products are responsible for a significant proportion of unintentional poisonings in children and are regularly reported among the top five agents implicated in pediatric poisoning exposure. This most likely reflects the ubiquitous nature of these agents within the child's environment and the ease of accessibility to children. Most household cleaning products appear attractive to children because of their color, scent, and brightly colored packaging. Fortunately, the high frequency of exposure to these toxic products is not associated with a similar frequency in morbidity. These agents contribute to less than 2% of the overall mortality due to poisonings in the under-5 age group. Among thousands of innocuous products present within the household, very few are hazardous. The big challenge for pediatricians and toxicologists is to identify the few rare life-threatening situations where definitive intervention is needed.

### Bleach

Household bleach solutions contain approximately 10% sodium hypochlorite. Children usually do not ingest them in significant quantity, as they are extremely unpalatable. The fumes typically release small amounts of hypochlorous acid and chlorine gas. Commonly observed effects include nausea, vomiting, eye irritation and diarrhea. More severe exposures may have burns in the lips, mouth and oropharynx and even laryngeal edema and

**Table 4** Characteristics of poisonous mushrooms

<i>Class</i>	<i>Mechanism of action</i>	<i>Features</i>	<i>Management</i>
Amanita mushrooms	Cyclopeptide alpha-amanitin inhibits RNA polymerase	GI irritation Hepatic failure, encephalopathy Renal toxicity Death by 2–6 days	Supportive Activated charcoal, N-acetylcysteine
Monomethylhydrazie mushrooms e.g., Gyromitra	Gyromitrin/monomethylhydrazine inhibits GABA formation	Mental confusion Progressive ataxia, seizures	Pyridoxine
Hallucinogenic e.g., Psilocybe	Structural similarity to serotonin	Euphoria Hallucinations Tachycardia, hypertension	Self-limiting
Muscarinic e.g., Clitocybe	Cholinergic agonist	Salivation, lacrimation, diaphoresis, urination, diarrhea	Atropine
Coprine mushrooms e.g., Coprinus	Inhibits acetaldehyde dehydrogenase	Edible mushroom, interaction only when taken with alcohol nausea, vomiting, flushing, tachycardia	Self-limiting

Abbreviation: GABA,  $\gamma$ -aminobutyric acid.

stridor. Ingestion of less than 100 mL of household bleach rarely leads to serious problems. Ingestion of fluids, especially milk, should be encouraged.

Esophageal injury is uncommon and is usually associated with concentrated solutions (industrial bleach may contain up to 50% sodium hypochlorite) or the ingestion of large volumes. Children at risk of esophageal damage should be hospitalized with careful monitoring of fluid and electrolyte balance. The presence of more than two symptoms may suggest esophageal involvement though none of the symptoms are 100% accurate in predicting esophageal injury. Early endoscopic examination is warranted where the suspicion is high.

### Disinfectants

These agents contain a variety of potentially toxic ingredients—hydrochloric acid (10%), sodium alkyl benzene sulfonate, sodium alkene sulfonate and others. However, since in most commonly available products, these toxic components are present in very small amounts, serious adverse effects are uncommon. Symptoms are usually mild and limited to areas of direct exposure like irritation of the oral mucosa and brief gastrointestinal upset. Fluid intake should be encouraged in an attempt to dilute and disperse the harmful agents. Children who are asymptomatic especially if they have ingested very small amounts (< 10 mL) may be discharged home. Consumption of large quantities of these agents, or even small quantities of concentrated solutions can lead to life threatening manifestations like local corrosive effects, aspiration pneumonia, metabolic acidosis, CNS depression and hepatic as well as renal injury. Phenol based derivatives pose the greatest risk (e.g., chloroxylenol, active ingredient of Dettol).

### Detergents

These are ubiquitous agents in every household and can be classified based on their chemical properties into three main categories—nonionic, anionic, and cationic. The first two categories (non-ionic, anionic) of detergents have low toxicity and children need to be observed only if respiratory symptoms are present (can result from foam aspiration). Most domestic cleaners do not contain cationic detergents, such as benzalkonium chloride and cetrimide. Concentrated solutions of these chemicals can produce corrosive effects. Like in the case of bleach, oral fluids should be encouraged and after a brief period of observation, asymptomatic children can be discharged. Management of corrosive ingestion is discussed elsewhere.

### Alcohol, Perfumes and Mouthwash

Ethanol is a common organic solvent found in alcoholic drinks, perfumes, aftershaves, mouthwash, etc. In children, most cases of ethanol poisoning result from ingestion of large quantities of household substances having a low concentration of ethanol such as mouth wash. Concentrated solutions, being more irritant, are rarely ingested by children.

Ethanol being a CNS depressant, can lead to respiratory compromise. Alcohol dehydrogenase present in the liver metabolizes ethanol with nicotinamide adenine dinucleotide (NAD) as cofactor. As NAD is required for multiple metabolic pathways, competition from large quantities of ethanol impairs several metabolic processes resulting in acidosis and impaired gluconeogenesis. Hypoglycemia can result from impaired gluconeogenesis especially in young or fasted children as a result of depleted glycogen stores.

Activated charcoal is not indicated as it does not absorb organic solvents like ethanol. Gastric lavage and induced emesis also may be ineffective as ethanol is rapidly absorbed across mucous membranes. If facilities are available, blood samples should be taken at least 1 hour after ingestion for estimating blood ethanol levels. However, treatment is determined on clinical grounds and mainly supportive. Dehydration and hypoglycemia should be corrected with careful attention to fluid balance as cerebral edema also can occur. A multitude of specific therapies have been tried, largely in adult patients with ethanol poisoning. Most of these aim to decrease the need and duration of supportive therapy. Drugs like flumazenil and naloxone for reversing CNS depression and forced alkaline diuresis for rapid elimination of ethanol are ineffective. Fructose can increase availability of NAD and has been tried as an intravenous infusion to enhance ethanol metabolism. But it can result in adverse effects like lactic acidosis and osmotic diuresis. Hemodialysis, though invasive, is very effective in treating patients with documented high blood ethanol levels (> 300 mg/dL).

### Nail Varnish Removers

These cosmetic agents usually contain acetone or ethyl acetate. Acetone, being an organic solvent is easily absorbed from the stomach and mucous membranes. Similar to other organic solvents, it causes local irritation in exposed areas, vomiting, and CNS depression. Metabolic derangements observed with acetone ingestion include ketosis, acidosis, and hyperglycemia. An estimate of the amount ingested, if possible, can be helpful. Those who have consumed more than 2 mL of pure acetone should be

kept under observation for 2 hours and if asymptomatic can then be discharged. Activated charcoal may not be beneficial as organic solvents like acetone bind poorly to acetone.

Symptomatic children should be hospitalized and offered supportive measures. Insulin may be required to control hyperglycemia and significant alteration in sensorium may necessitate mechanical ventilator support. Acetone can damage renal tubules and hence renal function should be monitored carefully. Ethyl acetate also can cause mucosal irritation, but unlike acetone, large quantities are required to produce CNS toxicity.

Nail varnish is usually available in small containers and ingestion of such small volumes is unlikely to produce significant damage though it contains a variety of potentially toxic ingredients.

### Toothpaste

Most of the children exposed to toothpaste with fluoride ( $> 6$  mg of fluoride/kg is toxic) typically have a benign course of recovery in the hospital. The most commonly observed adverse effects being nausea and vomiting resulting from gastric irritation. Large exposures ( $> 40$ – $50\%$  of the paste tube) are unusual, but can result in significant toxicity, including hypocalcemia, hypomagnesemia, cardiac rhythm disturbances and CNS features such as tremors or seizures. Treatment is primarily supportive.

### Naphthalene Poisoning

Naphthalene is a polycyclic aromatic hydrocarbon that is commonly encountered in indoor and outdoor environments. It exists primarily as a vapor at ambient pressure due to its high vapor pressure and has a strong, characteristic odor. It is insoluble in water, but highly soluble in oil, which may lead to its absorption through skin, especially in babies. There are numerous sources of naphthalene in the environment. It is a component of crude oil, and is used as a pesticide in mothballs, as deodorant in lavatories and in dyes. Naphthalene mothballs contain 99.9% naphthalene, and can range in weight from 0.5 g to 5 g.

The majority of exposure to naphthalene in the environment occurs through inhalation, while other pathways include dermal contact with and ingestion of naphthalene-containing products. Dermal exposure can occur from direct contact with mothballs, as well as items stored in enclosed spaces with naphthalene-containing mothballs. Incidents of serious medical outcomes, including acute hemolytic anemia, have been reported in association with dermal exposure in newborns to diapers and blankets that have been stored with mothballs.

### Pathophysiology

Naphthalene undergoes hepatic metabolism, and is oxidized to alpha-naphthol and other metabolites. It has recently been reported that certain cytochrome P450 enzymes that are highly expressed in the human respiratory tract are also capable of catalyzing these metabolic transformation reactions. The metabolites of naphthalene produce oxidative stress, leading to the formation of methemoglobin and the oxidation of hemoglobin which results in the formation of visible Heinz bodies and increased susceptibility of the RBC to hemolysis. Acute hemolysis can subsequently lead on to hemoglobinuria and blockage of renal tubules due to deposition of acid hematin, causing renal injury and failure. Laboratory studies have also demonstrated that naphthalene induced production of free oxygen radicals results in lipid peroxidation and deoxyribonucleic acid damage.

### Clinical Features

The onset of signs and symptoms usually occurs 1–2 days after exposure because of the slow rate of metabolism of naphthalene to its oxidative metabolites. After ingestion, vomiting, diarrhea and

fever appear in 1–2 days, followed on the 3rd to 5th day by an acute hemolytic crisis as evidenced by pallor, mild jaundice and pigmented urine. Children may present with severe loin pain, burning sensation in the urethra and strangury. Severe toxicity may result in hepatic or renal damage, cyanosis due to methemoglobinemia, tachycardia, respiratory distress, convulsions, coma and death. Five to six days after ingestion, the hemolytic process ends and if the patient survives this stage, then recovery is rapid.

When exposed through the inhalational route, it can cause headache, nausea, vomiting, mental confusion, visual disturbances, conjunctivitis and dermatitis.

Hematological changes, occurring as early as one day after initial exposure in severe cases, lead to a Heinz-body hemolytic anemia with fragmented cells, spherocytosis in peripheral smear and a sharp fall in hemoglobin, often with concurrent leukocytosis. Reticulocytosis follows with subsequent gradual restoration of the normal blood values except in the most severe cases.

### Management

Close monitoring, in anticipation of complications, is essential for at least a week following exposure. Induction of emesis is not recommended. Treatment is mainly supportive. Cathartics like magnesium sulfate and activated charcoal can be tried. It is advisable to avoid milk or fatty foods for at least 2–3 hours postexposure because of the high fat solubility. Alkaline diuresis is usually done to prevent deposition of acid hematin crystals in cases with hemolysis. Child may require transfusions of packed RBCs because of the sudden rapid fall in hemoglobin.

Clinical suspicion of methemoglobinemia should arise when there is cyanosis that does not respond to high-flow oxygen with no obvious cardiorespiratory causes. Pulse oximetry may become unreliable in the setting of methemoglobinemia. A co-oximeter type of blood gas analyzer is needed to directly measure the oxygen saturation and methemoglobin (metHb) levels. Standard treatment includes the use of methylene blue (indicated when metHb  $> 30\%$ ) and exchange transfusion. Methylene blue increases the rate of conversion of metHb to Hb by accepting an electron [in the presence of nicotinamide adenine dinucleotide phosphate and metHb reductase], to form leukomethylene blue, which can then donate this electron to reduce metHb. The use of NAC as a direct reducing agent in treating methemoglobinemia is still being investigated.

### Eucalyptus Oil or Essential Oil Poisoning

Eucalyptus and neem oils have been used as a traditional remedy for a variety of common ailments, mostly involving respiratory tract. It is also used as an antiseptic, repellent, and as an agent for fragrance and flavoring. Most prevalent is the standard cineole based oil of eucalyptus (minimum 70% cineole). Other constituents include pinene, limonene, beta citronellol, citral and geraniol.

The safe adult dosage has been estimated to be 0.06–0.2 mL. Death has occurred even after ingestion of 4–5 mL, and is usual after 30 mL.

### Clinical Features

It acts as a local irritant causing burning sensation in mouth and throat, abdominal pain and vomiting. Inhalation can cause bronchospasm leading to tachypnea and wheezing, however respiratory depression occurs in severe intoxication. The exact mechanism causing CNS features is not yet known; it causes CNS depression manifested by diminution or loss of reflexes, depressed consciousness progressing to coma. Convulsions or tonic posturing may be a prominent manifestation in children, although it is rarely reported in adults. Ataxia and pulmonary involvement has been reported.

## Management

Management is primarily supportive. Attempts to induce vomiting should be avoided because of risk of aspiration. Gastric lavage may be performed, preferably after insertion of a cuffed endotracheal tube in the presence of CNS depression. Tonic posturing or seizures usually respond to intermittent diazepam. Mechanically ventilated patients may initially require higher pressures because of aspiration pneumonitis. There are isolated case reports of use of naloxone as an antidote and use of hemodialysis in eucalyptus poisoning.

## Neem Oil Poisoning

*Neem* is endemic in Indian subcontinent. Extract from its seed (*margosa* oil) has been found to have antifertility, antihyperglycemic, anti-inflammatory, antiulcer, antimicrobial, estrogenic, immune and insect repellent effects. Neem oil, as a traditional medical remedy, is used as antibacterial, antifungal, insect repellent, and treatment of skin diseases. The oil is a mixture of many steroids, triglycerides and terpenoids along with minimal amount of aflatoxins. It contains active ingredients like azadirachtin, nimbin, picrin, and sialin. The exact toxic dose is not known, but fatality has been reported even with ingestion of a few drops of neem oil and common with ingestion of 15–20 mL.

Azadirachtin, a complex tetranortriterpenoid, is implicated in causing the effects seen in neem oil poisoning. Azadirachtin manifests its toxicity possibly by interfering with mitochondrial bioenergetics, resulting in inhibition of the generation of the electrochemical proton gradient (primary form of energy generated in mitochondria) leading to cellular hypoxia.

## Clinical Features

Children manifest with vomiting and lethargy around 30 min to 1 hour following ingestion of neem oil. They have progressively worsening sensorium, seizures and metabolic acidosis. Hepatic toxicity as evident from an elevation in transaminases and a Reye syndrome like presentation has also been described. They can have sudden deterioration with fatality in the first 12–24 hours.

## Management

There is no specific antidote available, and gastric lavage is not recommended for neem oil poisoning. The management is primarily symptomatic and outcome is good in the absence of neurological manifestations. Neurological sequelae like vision loss and choreoathetoid movements have been reported.

## Camphorated Oils

Camphorated oils and derivatives of camphor act as CNS stimulants and also cause local irritation. Camphorated oil contains 20% camphor, while VICKS VapoRub, a commonly used remedy contains 4.3% camphor, 6% eucalyptus oil and 4% menthol. Camphor ingestion may manifest with poor sensorium and seizures, usually within 20–30 min after ingestion. Children present with burning sensation in mouth, abdominal pain and vomiting within 5–10 min of ingestion. The symptoms peak at around 90 min, and spontaneously resolve with supportive care.

Decongestant capsules use for common cold remedies usually have a mixture of essential oils. Accidental ingestion can produce irritation of the oropharynx, nausea, vomiting, and diarrhea. The predominant systemic effect, though rare, is CNS depression.

Nasal instillation can result in severe respiratory distress and even respiratory arrest has been reported.

## PREVENTION OF COMMON HOUSEHOLD POISONING

The risk mitigation strategies included new packaging requirements and precautionary labeling to protect toddlers and children from ingestion of such toxic substances, e.g., acceptable packaging includes tear and moisture-resistant sachets, and plastic containers that allow volatilization but no direct contact with the naphthalene.

Recommendations by the American Academy of Pediatrics include storing poisonous substances always in locked cabinets, preferably out of sight and reach of children. Household products should have child-resistant packaging and should always be kept in their original containers. All unused and leftover products, especially pesticides, should be disposed of properly. Proper educational programs targeting household chemicals and their use and storage should be developed and disseminated.

### IN A NUTSHELL

1. Poisoning in the household accounts for majority of poisoning episodes in children less than 5-year-old.
2. Explorative nature of children, attractive packaging and poor storage and disposal of dangerous agents within the household are the major predisposing factors.
3. Organophosphate and carbamates are among the most common causes of life threatening poisoning in children. The life threatening early clinical features are easy to identify (cholinergic toxidrome).
4. Patients who develop intermediate syndrome after organophosphate poisoning can die suddenly if not recognized early and given ventilator support.
5. Rodenticide poisoning involving yellow phosphorus (Ratol) has high fatality rate with very little early manifestations.
6. Among the life threatening plant poisons, oleander and datura are the most common, each with characteristic constellation of symptoms.
7. Most of the household products of daily use have limited toxicity unless consumed in large doses.
8. Antidotes are available for only very few household poisonings; prompt supportive therapy is the cornerstone of treating household poisonings.

## Chapter 9.5

# Corrosive Poisoning

Urmila Jhamb

Corrosives/caustics are a group of chemicals which cause severe injury to the tissue on contact by a chemical reaction. These are widely used for various purposes at home (especially cleaning) and in industry in both crystalline and liquid form. Corrosive substances may be acids, alkalis (most dangerous), oxidants and heavy metal salts. Corrosive ingestion in children is mostly accidental unlike adults where it is more often suicidal. Children are curious by nature and accidental ingestion of corrosives is due to their easy availability in and around the houses. Children less than 5 years are most commonly involved. Storage of acids in mineral water bottles or other household containers increases the risk as it can be mistaken for a drinkable fluid. Lack of supervision of children and poor living conditions in addition increase the hazard of ingestion of corrosives.

## EPIDEMIOLOGY

Corrosive ingestion may account for 0.3–0.9% of pediatric admissions. Death rates may range from 0% to 13% although later on esophageal strictures (OS) can form in 5–50% depending on severity of corrosive injury. The accidental corrosive poisoning is on the decline in high-income countries but it is quite significant in developing countries. A study from India compared the trends in childhood poisonings from 1993 to 2008 and it was found that the corrosives ingestion as percentage of all poisonings had been fluctuating between 4.3% and 12.3%. Some recent studies (2011–2013) reported this percentage as 7.6% (Chandigarh) to as high as 24.9% (Delhi). In India, there is poor regulation of sale of corrosive substances and they are freely available in households. Corrosive ingestion was reported to be the commonest among nondrug poisonings from Turkey, second most common after kerosene from Delhi and next after kerosene and organophosphorus from Chandigarh.

## ETIOLOGY

Common corrosives causing poisoning are listed in **Table 1**. The most common corrosive poisoning is variable in different countries. Studies from USA, Denmark, Israel, UK, Peru, Spain, Australia, Saudi Arabia, Turkey and Pakistan reported alkalis as the most frequently ingested corrosives. Majority of these are sodium hypochlorite or disinfectants and cleaning solutions containing sodium hydroxide. However, in India there is strikingly different scenario with acid ingestion occurring in majority of cases. Acids are often used as toilet cleaners in Indian homes.

## PATHOPHYSIOLOGY

Acids precipitate protein and cause coagulation necrosis. In this process, hydrogen ( $H^+$ ) ions desiccate epithelial cells producing an eschar. This leads to edema, erythema, mucosal sloughing, ulceration and necrosis of tissues. Alkalis cause liquefaction necrosis. This process includes dissolution of protein, collagen destruction, saponification of fat, cell membrane emulsification, submucosal vascular thrombosis (few hours after ingestion) and cell death.

Inflammatory response and development of granulation tissue continue in the next several days after corrosive ingestion. Because of these changes, esophagogastroduodenoscopy between the 5th and the 15th day after corrosive ingestion is not recommended.

**Table 1** Common substances causing corrosive ingestion

Acids	Alkalis
Sulfuric acid in car batteries	Caustic soda, i.e., sodium hydroxide (in household cleaners, laundry detergents and drain cleaners)
Hydrochloric acid for toilet cleaning (also in Lysol)	Sodium metasilicate or disilicates (in dishwasher powder)
Detergents containing sodium phosphate	Clinitest tablets (used to check urine sugar) have sodium hydroxide (also have copper sulfate, citric acid and sodium carbonate)
Nitric acid as metal cleaner	Potassium hydroxide (industrial paint strippers)
Phenol and boric acid as disinfectant	Ammonia in household cleaners (ammonium hydroxide)
Hydrofluoric acid as swimming pool cleaner and rust remover	Phenol
Oxalic acid as rust removers	Potassium permanganate
Vinegar (acetic acid)	Disc batteries (contain 45% solution of potassium hydroxide or sodium hydroxide; if lodged in esophagus can leak and perforate)
Formic acid used in the rubber tanning industry	Oxidizing agents
Aqua regia or Goldsmith's solvent is a 3:1 mixture of hydrochloric acid and nitric acid	Sodium hypochlorite (household bleach) is alkaline oxidizing corrosive
	Hydrogen peroxide in hair dyes
	Heavy metals
	Zinc chloride
	Mercury chloride

Consequently, there is little collagen deposition until the second week after ingestion. After 3 weeks, tissue fibrosis occurs during healing and causes narrowing of esophageal and/or stomach lumen forming strictures (**Table 2**).

Factors that determine the corrosive potential are concentration (industrial use products are more concentrated and more corrosive while hand use products are less corrosive), physical form (solids cause deep but localized injury in oral cavity while liquids cause extensive injury in esophagus and stomach), amount ingested, duration of contact, pH of agent (pH <2 and >12 are more corrosive), presence or absence of food in stomach.

Alkalis are usually colorless, tasteless, odorless and more viscous. Therefore, these are ingested in larger amount. The combination of their viscous nature and the process of liquefaction keep them in mucosal contact for a longer time and therefore, lye produces deeper (transmural) injuries. Acids are ingested in smaller quantity because of their pungent odor and bad taste.

**Table 2** Consequences of caustic injury

Necrosis	Within seconds of exposure to caustic agent
Ulceration and perforation	Within 24–72 hours of exposure
Fibrosis	Occurs by 14–21 days of exposure
Stricture	After weeks to years of exposure
Carcinoma formation	After decades of alkali exposure

They are rapidly swallowed and thus, may cause more gastric than esophageal injury.

Many studies have however reported that the esophageal injuries are common even with acid poisoning. The coagulum formed in acid ingestion prevents its transmural spread and therefore full-thickness or perialimentary injury is less common. Both acids and alkalis cause fibrosis, cicatrization and stricture formation.

## CLINICAL PRESENTATION

Children present with burns around and in the oral cavity with drooling of saliva. There is pain in lips, mouth, throat, chest and abdomen. Dysphagia, nausea, vomiting, hematemesis and melena may occur. Hoarseness, dysphonia, and stridor can occur due to laryngeal edema. Respiratory distress can occur due to airway obstruction, chemical pneumonitis or pulmonary edema.

Gastrointestinal (GI) perforation is an uncommon but major complication of corrosive ingestion seen in 6–7% cases. This usually occurs in the first 48 hours but can be delayed up to 14th day. Chest pain and presence of mediastinal air may point to esophageal perforation. The major clinical findings of gastric perforation are abdominal pain, tenderness and distension with radiologic evidence of pneumoperitoneum.

## TREATMENT

### Immediate Management after Ingestion

Immediately mouth should be rinsed (skin or eyes if involved should be flushed) and any remaining corrosive should be removed. If the child is having difficulty in breathing, child should be allowed to be in position of comfort. Efficacy of milk or water for diluting/neutralizing corrosive has not been confirmed by many controlled studies. Milk must be given within the first hour to be effective and this may compromise the urgent endoscopy. Other neutralizing agents are mild vinegar, lemon or orange juice for alkali and milk, eggs or antacids for acids. Some authors feel that the neutralization reaction produces heat which can cause further injuries of upper GI tract. Sodium bicarbonate produces carbon dioxide increasing the risk of perforation and is not recommended for neutralization of acids. Thus, no neutralizing substance, water or milk has any proven benefit.

### Early Treatment in Hospital

#### Initial Stabilization

If there is history of minimal corrosive ingestion and no oropharyngeal burns on examination, then the patient requires only observation in the emergency room. If there is respiratory distress along with stridor or hoarseness of voice then the patient requires admission in intensive care unit. Urgent endotracheal intubation should be done as airway edema may rapidly progress over minutes to hours. Supraglottic edema causing acute upper airway obstruction may require tracheostomy. Delay in prophylactic airway protection may make subsequent attempts at intubation or bag mask ventilation difficult or impossible. There is no clear role for systemic steroids or adrenaline nebulization in decreasing airway edema and reducing the need for endotracheal intubation (there are some reports of response to adrenaline nebulization and this may be tried for a brief period but intubation should not be delayed for long if there is no response). Acute circulatory compromise may occur due to hypovolemia because of hemorrhage, vomiting and third-space sequestration. Hemodynamic correction can be done by replacement with crystalloid fluids.

## Decontamination

Gastric lavage and induced vomiting are contraindicated because esophagus is re-exposed to regurgitated corrosive causing additional injuries. Activated charcoal does not bind to corrosives. False passage and esophageal perforation can occur by blind placement of a nasogastric tube. However, if a child reaches the hospital with a nasogastric tube already inserted, stomach contents may be aspirated. Exceptions to general rules of decontamination are zinc chloride and mercury chloride poisoning because both cause systemic toxicity.

### Diagnostic/Prognostic Upper Gastrointestinal Endoscopy

Mostly it is agreed that since severity of oropharyngeal injuries is not a reliable indicator for esophageal or gastric injuries, upper GI endoscopy should be performed early by 12–24 hours (but can be safely performed up to first 72–96 hours). This should be avoided from 4th to 14th day because of the healing process occurring intensively during this period and there is risk of perforation. Third-degree hypopharyngeal burns are an absolute contraindication for endoscopy. Other relative contraindications are respiratory distress, hemodynamic compromise, peritonitis and mediastinitis (suspected perforation) as well as mild ingestion (asymptomatic patients with normal oral/upper airway examination).

Children with first-degree injuries may be initially given liquids and within 24–48 hours a regular diet is allowed (**Table 3**). They may be followed up on an outpatient basis. In patients with IIB and III degree of damage, food particles can exacerbate the inflammation by entering the granulocytes of the esophageal wall. In these cases, *esophageal rest* is recommended and the child may be fed by gastrostomy or jejunostomy tube. In those who can swallow their saliva by 48 hours, intake of milk/nutritional liquids is recommended by some authors and surgical gastrostomy to be reserved for children who are unable to swallow liquids or saliva. Patients with second- or third-degree burns may need a barium swallow or repeat endoscopy after 3 weeks. First-degree injury rarely causes stricture. Second-degree injury infrequently causes and third-degree injury often causes strictures. Most frequent sites of esophageal stenosis are the cricopharynx, at the level of the aortic arch or bifurcation of trachea and the lower esophageal sphincter. The stomach and duodenum are usually spared but pyloric or antral stenosis can occur.

Some clinicians believe that asymptomatic patients may not be unnecessarily subjected to endoscopy. Uygun et al found that DROOL Scores (**Table 4**) were significantly lower (more severe) in patients with subsequent OS than those without. A DROOL Score less than and equal to 4 was a significant predictor of esophageal stenosis (100% sensitivity, 96% specificity, 85% positive and 100% negative predictive values). The authors also believed that endoscopy assesses only the gastroesophageal mucosa, whereas esophageal muscle layer burns and necrosis leading to esophageal stenosis (OS) are not visualized. Similarly, Bicakci et al reported 350 cases of corrosive ingestion in which enteral feeding was discontinued for 24 hours and after that those who did not tolerate enteral feeding were started on parenteral feeding. Early esophagoscopy or gastrostomy was not done in any patient. In patients with persistent dysphagia, contrast study of upper GI tract was performed within 3 weeks after injury. If there was OS, a dilatation program was initiated. Five percent patients

**Table 3** Severity of esophageal injuries caused by corrosives on upper gastrointestinal endoscopy (classification by Zargar\*)

Grade of injury	Description of injury
0	Normal mucosa
I	Superficial mucosal edema and erythema
II	Mucosal and submucosal ulcerations
IIA	Superficial ulcers, erosions, blisters, exudates hemorrhage
IIB	Deep discrete or circumferential lesions
III	Transmural ulcerations with necrosis
IIIA	Focal deep gray or brownish-black ulcers
IIIB	Focal deep gray or brownish-black ulcers
IV	Perforation

\*There are some other classifications available with minor differences.

**Table 4** The DROOL Score for caustic ingestion

Component of acronym	Signs and symptoms	Score 0	Score 1	Score 2
Drooling	Drooling of saliva	≥12 hours	<12 hours	No
Reluctance	Reluctance to eat or dysphagia or food intolerance	≥24 hours	<24 hours	No
Oropharynx	Oral and oropharyngeal burns	Severe lesions*	Edema, hyperemia	No
Others	Number of other signs and symptoms, e.g., persistent fever, hematemesis, abdominal tenderness, retrosternal pain and dyspnea	≥2	1	No
Leukocytosis	Total leukocyte count (/mm <sup>3</sup> )	≥20,000	<20,000	No

\*Friability, hemorrhage, erosion, blisters, whitish membrane, exudates, ulcers and necrosis.

required dilatation and in all patients, the symptoms were completely relieved. A median of five dilatation sessions (1–19 dilatations) were required. Kiriştioglu et al suggested that there is no need for endoscopy in liquid household bleach ingestion until there is persistent drooling as this agent is mild corrosive and they found hardly any strictures in these patients. Therefore, the type of corrosive ingested is also important. Hair straighteners and relaxers containing calcium or lithium hydroxide are highly alkaline but they rarely cause severe injury.

It is, therefore, suggested that in resource limited settings in developing countries, patients may be fed liquids as soon as they can swallow saliva. Those who cannot swallow may be subjected to gastrostomy or jejunostomy. Patients with persistent dysphagia may be subjected to endoscopy at 10–14 days or barium swallow is done at 3 weeks for detection and dilatation of stricture.

There is no role of steroids in first-degree burns as these heal well with no stricture formation. Some authors recommend steroids within 48 hours in grade II injury (especially IIB as IIA injury infrequently causes strictures). Steroids are

contraindicated in third-degree burns because of a higher risk of developing perforations. Various protocols, e.g., dexamethasone (1 mg/kg/day for 3 days and gradually weaned at 10 days) or prednisolone (2 mg/kg/day intravenous till patient starts taking orally and then 1–2.5 mg/kg/day orally for 3 weeks and then tapered) or methylprednisolone (2 mg/kg/day for 2–3 weeks and then tapered) or high-dose methylprednisolone (1 g/1.73 m<sup>2</sup>/day for 6–15 days) have been tried. In most studies, they have not found to prevent stricture formation. A review of 14 studies by Oakes showed no measurable benefit of the use of systemic steroids.

Tissue destruction from caustic injury increases the risk of infection by enteric organisms. Antibiotics are not recommended prophylactically in corrosive poisoning until there is evidence of infection but are recommended in cases with GI perforation. Gastroenterologists routinely recommend proton-pump inhibitors and H<sub>2</sub>-blockers in corrosive ingestion.

An approach to management of corrosive ingestions in children is shown in **Flow chart 1**.

### Long-term Treatment

The most common late complication is OS or gastric stenosis. These may appear from 3 weeks to 3 months after corrosive ingestion and sometimes even after 1 year. Isolated corrosive pyloric stenosis without esophageal involvement is an uncommon phenomenon but can occur sometimes (reported in 5% cases in one study). The most severe gastric injuries occur in antrum or pylorus where the corrosive remains for a long time. Gastric obstruction is suggested by weight loss and feeling of full stomach, nausea or vomiting.

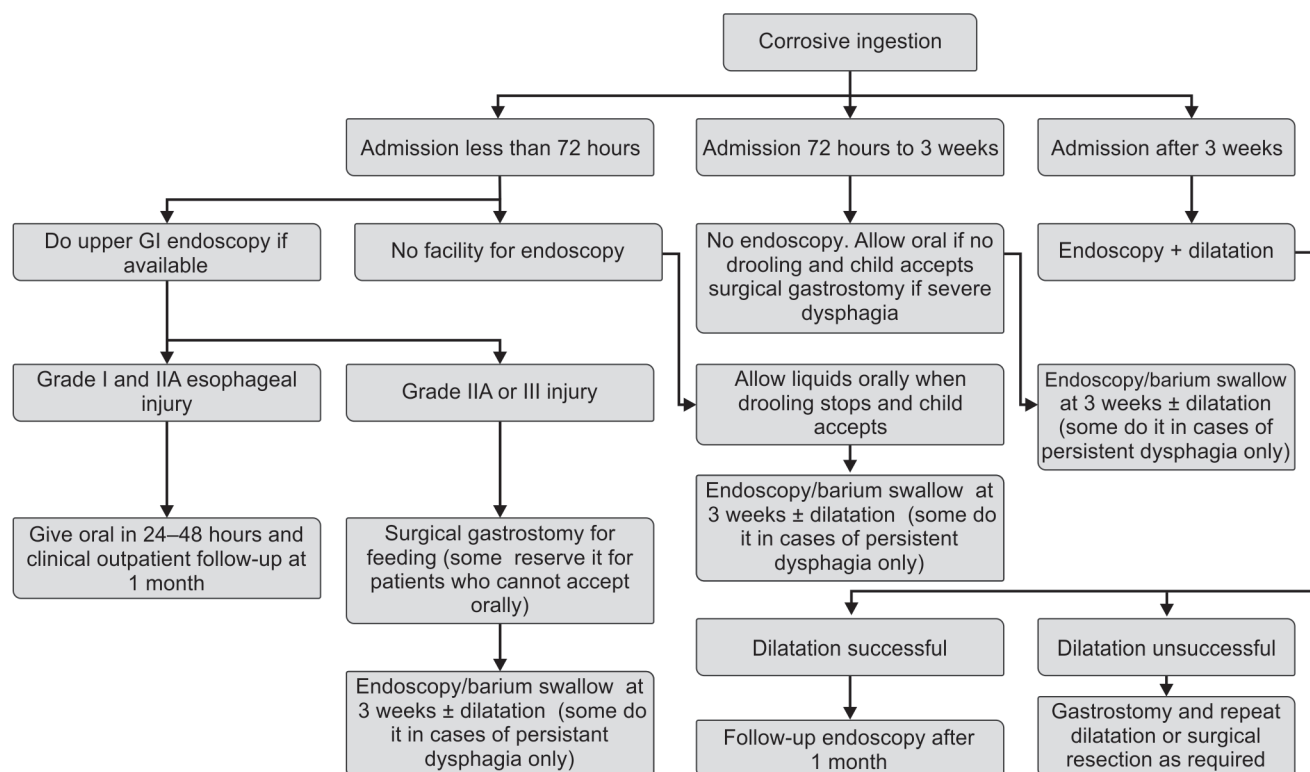

Esophageal and stomach cancer may occur decades later (25–50 years). Only few cases of postcorrosive carcinoma are reported from India. Lye ingestion has been associated in almost all cases of postcorrosive carcinoma reported in the world literature. It may be possible that in India, low incidence of esophageal malignancy may be due to overwhelmingly common ingested corrosive being acid.

Corrosive OS may be managed by endoscopic dilatation or by surgical resection. Dilatation by rigid Savary bougies (much more common and several Indian centers have reported good results) or balloon dilatation at regular intervals can be carried out. Dilatation is done till a lumen size of 15 mm or the size of thumb of child is achieved and there is no dysphagia. Subsequently, whenever dysphagia recurs dilatation is repeated. Average duration of stricture resolution has been reported to be 15–16 months by dilatation with bougies/balloon. Recurrent strictures can occur.

In patients with esophageal injuries of grade IIB and III, special intraluminal stents (made of silicone rubber or polyflex) may be placed under endoscopic guidance to prevent or treat esophageal stenosis. However, the efficacy is less than 50%, with a high migration rate (25%). Moreover, cost and experience are other factors to be considered.

Application of mitomycin (variable concentrations used in literature, e.g., cotton soaked in mitomycin 0.4 mg/mL solution for 5 minutes or 1 mg/mL for 2 minutes) at the stricture site after dilatation has been found to improve results of dilatation and require less sessions of dilatation. Mitomycin inhibits DNA-dependent RNA synthesis which reduces fibroblastic proliferation in submucosa and gives the mucosa enough time to creep and cover the stricture site, which prevents restenosis.

**Flow chart 1** Suggested management of corrosive ingestions in children

Though nasogastric tube placement may ensure patency of the esophageal lumen, the tube itself can contribute to the development of long strictures and routine use is not uniformly recommended. It may form a nidus for infection and worsen gastroesophageal reflux, causing delay in mucosal healing. There is a potential risk of esophageal or gastric perforation by insertion of nasogastric tube in acute phase. However, enteral nutrition through a nasogastric tube has been demonstrated to be as effective as jejunostomy feeding in maintaining nutrition in such patients, with a similar rate of stricture development. Positioning a nasogastric tube has another advantage of providing a lumen for dilatation, in case a tight stricture develops. Therefore, after caustic injuries the placement of a nasogastric tube may be considered, but the decision should be made with caution and done on a case-by-case basis.

### Surgery

Surgery is indicated if dilatation fails or there is complication after endoscopic dilatation such as perforation. If there is complete stenosis, fistula formation or location/length of the stricture is such that endoscopic management is impossible then surgery is the only alternative. Broadly, surgical management consists of either esophageal bypass (esophagus left in situ) or esophageal resection and replacement with a conduit. If children are admitted when the stricture is already well established, dilatations are more difficult and followed by a significantly higher recurrence rate than early procedures and more future need for esophageal replacement.

The American Society of Gastrointestinal Endoscopy recommends surveillance of patients 15–20 years after corrosive ingestion, endoscopic examination every 3 years and low threshold for evaluation of dysphagia.

### Psychosocial Management

At the time of injury, there is often a sense of guilt/blame and anxiety over the child's survival and future morbidity. The medical team managing the child needs to support the child's parents and caregivers. Long-term profound psychosocial impact of disfiguring corrosive injuries on the child has been documented. Children may develop behavioral or educational problems such as delinquency and school avoidance. These need to tackle whenever detected.

### PREVENTION

Corrosive agents need to be stored out of reach in a locked, child-resistant cupboard. Limit the concentration of such materials and make their containers childproof. Children less than 5 years need to be supervised at all times. There is need for legislation to regulate sale of concentrated corrosives.

## IN A NUTSHELL

1. Corrosive substances may be acids, alkalis (most dangerous), oxidants and heavy metal salts. Ingestion in children is mostly accidental at home.
2. In India majority of ingestions are due to acid unlike most other countries where alkali ingestion is more common.
3. Acids cause coagulation necrosis and alkalis cause liquefaction necrosis.
4. Acids tend to be ingested in smaller amounts as they have pungent odor and unpleasant taste, are swallowed rapidly after ingestion and may cause more gastric injury than esophageal.
5. Alkaline agents are usually colorless, tasteless and odorless and are therefore ingested in larger amount. Due to viscous nature and liquefaction necrosis they remain in mucosal contact for a long period of time and produce deeper injuries.
6. Efficacy of milk and water or other neutralizing substances as an antidote has not been confirmed.
7. Gastric lavage, induced vomiting are contraindicated. Activated charcoal does not bind to corrosives.
8. Endoscopy if available is performed early to detect the degree of injury to esophagus and stomach. Feeding can be started when patient can swallow saliva.
9. The most common late complications are esophageal and gastric strictures/stenosis. Steroids do not offer any benefit in prevention of stricture formation.
10. Treatment for OS is by dilatation at regular intervals by bougies (mostly) or balloon. Surgical management is indicated if there is failure of dilatation.

## Chapter 9.6 Snakebite

S Mahadevan, R Ramesh Kumar

Approximately 5 lakhs envenomings and 20,000 deaths occur each year due to snakebite worldwide. The maximum affliction of envenoming of more than 100,000 per year has been reported in South Asia, Southeast Asia and sub-Saharan Africa region. In the South East Asian region, India still contributes to highest snakebite related mortality. In tropical region like India, most of the deaths in snakebite are due to the late referral of victim to the hospital where anti-snake venom (ASV) is available for definitive management. Apart from late referral of victim factors contributing to high deaths are: (1) lack of community awareness about occupational hazards (2) not adopting the simple preventive measures (3) use of harmful first aid practices such as tight tourniquets, cutting and suction of snakebite site and (4) lack of confidence of primary care physician to administer ASV at peripheral setting in the fear of anaphylaxis of ASV. The *National representative snakebite mortality survey of India* found that snakebite related deaths remained an underestimated and underreported cause of accidental deaths. Occurred more commonly in the rural setting, in males than females and peaked at age group of 15–29 years and during the monsoon months of June to September. In India annual snakebite deaths were highest in Uttar Pradesh, Andhra Pradesh and Bihar.

### POISONOUS SNAKE SPECIES IN INDIA

All snakebites are not venomous. Venomous snakes are distributed widely in almost all countries situated in the western hemisphere from latitudes of 50°N to 50°S and in the eastern hemisphere from latitudes of 65°N (Scandinavia) to 50°S. Sea snakes are mainly distributed in the Indian Ocean and Pacific Ocean from latitudes of 30°N to 30°S. On land, venomous snakes have been found in

altitudes 4,000 m and higher in the Americas and Himalayas from sea level, and sea snakes can travel up to depths of 100 m and more in the oceans. In India, more than 330 species of snakes are found of which more than 60 species are venomous. However, only four snake species, namely common krait (*Bungarus caeruleus*), common cobra (*Naja naja*), saw-scaled viper (*Echis carinatus*) and Russell's viper (*Daboia russelii*) are being considered for most of the medically significant venomous snakebites in India (Figs 1A to D). However, this practice of considering only these four poisonous snakes has led to nonidentification of other unnoticed poisonous snake species contributing to more deaths. The discovery of the hump-nosed pit viper (*Hypnale hypnale*) causing life-threatening symptoms is an example of this situation. The ASV manufacturers produce antivenom only against these four major snake species due to this nonrecognition. In India, particular species are distributed in particular region: central Asian cobra (*Naja oxiana*) in the far north-west, greater black krait (*B. niger*) in the far north-east, monocellate cobra (*N. kaouthia*) in the north-east, hump nosed pit-viper (*Hypnale hypnale*) in the south-west coast and Wall's and Sind krait (*B. walli* and *B. sindanus*) in the east and west part of India, may be responsible for additional fatality due to snakebite envenomation. In order to entirely identify all the medically significant snake species in India, we need to shed the old order of *The Big Four*.

### PATHOPHYSIOLOGY

Snake venom is a complex mixture of various compounds; the venom of any given snake species might contain 100 and more different types of toxic and nontoxic proteins and peptides, and also contain nonprotein, carbohydrates, lipids, amines and various small molecules. Ninety percent of venom constituents are pharmacologically active peptides and proteins, which are responsible for almost all of its biological effects and clinical manifestations. The venom composition is exclusive to each species only, i.e., *species-specific*—e.g., neurotoxins in the venom of elapids, and cytotoxic and anticoagulant/procoagulant substances

**Figures 1A to D** The *Big Four* highly venomous snake in India. (A) Common cobra (*Naja naja*); (B) Russell viper (*Daboia russelii*); (C) Saw-scaled viper (*Echis carinatus*); (D) Common krait (*Bungarus caeruleus*)

in the venom of vipers and colubrids. The amount of venom injected is not associated to the number of bites or the size of the snake, or it is fangs.

Cytotoxic enzymes like phospholipases A2, metalloproteinases cause edema, blister and tissue necrosis at the bite site of a venomous snake through activation of proinflammatory pathways. Further, these enzymes support the release of other inflammatory mediators like bradykinin, prostaglandin, cytokines and sympathomimetic amines, which induce pain at the bite site. Peptides present in the venom cause hypotension via inhibition of angiotensin-converting enzyme (ACE). Safarotoxins and endothelins may cause the myocardial ischemia and cardiac arrhythmias as these toxins are potent coronary artery vasoconstrictors.

Neurotoxins cause muscle paralysis by acting on neuromuscular transmission either at presynaptic or postsynaptic levels. However, neurotoxins usually do not enter into the central nervous system via the blood-brain barrier. Phospholipase A2 complexes such as  $\beta$ -neurotoxins—taipoxin, paradoxin, trimucrotoxin, viperotoxin, pseudocerastes, textilotoxin, and crotoxin cause the inhibition of acetylcholine release from the presynaptic vesicles. Since these toxins affect formation of new acetylcholine vesicles at presynaptic terminal, these inhibitions are likely to be irreversible. Neurotoxins such as  $\alpha$ -neurotoxins are three-finger protein

complexes that act at postsynaptic level and have a curare-like action. Moreover, these types of toxins usually cause reversible blockage of acetylcholine receptors at postsynaptic terminal. Iridotoxin remains the best-characterized example of  $\alpha$ -neurotoxin. Complex neuromuscular transmission obstruction may occur as some venom composition comprise of both  $\alpha$ - and  $\beta$ -neurotoxins.

Metalloproteinases, via activation of factor X and serine proteases, act as potent activators of prothrombin. The snake venom C-type lectins and some three-finger toxins may promote or inhibit platelet aggregation due to its anticoagulant or procoagulant activity. Due to certain surprising effects like anti-inflammatory, immunomodulatory and antitumor of snake venom, it is under experiment for use as likely healing agents for various diseases. Patients suffering from acute ischemic stroke have been treated for years with toxin *ancrod*, a serine protease derived from the venom of Malayan pit viper due to its defibrinogenating properties. **Table 1** summarizes the mechanisms of action of snake venom proteins and peptides.

## CLINICAL FEATURES

### Systemic Features

Envenomed patients may experience arterial hypotension and shock, due to venom-induced systemic vasodilation and

**Table 1** Snake venom proteins and peptides: Mechanisms of action

Type of protein/Peptide	Example of toxin	Snake species	Mechanism of action
Acetylcholinesterase	—	<i>Elapidae</i>	Destruction of acetylcholine resulting in paralysis of muscles
Anticholinesterase	Fasciculins	<i>Dendroaspis spp</i>	Depolarizing neuromuscular block resulting in paralysis (dendrotoxins)
Calcium dependent-type galactose-binding lectins	Rhodocytin	<i>Viperidae, Elapidae</i>	Mainly affects the platelet
Cysteine-rich secretory proteins	—	<i>Elapidae, Viperidae</i>	Inhibition of the smooth muscle
Cysteine proteinase inhibitors	Cystatin	<i>Viperidae, Elapidae</i>	Inhibit metalloproteinases
Cobra venom factor, complement C3	Cobra venom factor	<i>Elapidae, Viperidae</i>	Local tissue damage
Disintegrin and metalloproteinase (ADAM)	Hemorrhagins (atrolysins, jararhagin); procoagulants (fibrolase, ecarin, Russell's viper venom factor-X activator)	<i>Viperidae, Elapidae</i>	Endothelial damage, bleeding, necrosis
Endothelins	Sarafotoxins	<i>Atractaspis spp</i>	Hypertension, effects on myocardial muscle
Factor-V, factor-X activators	—	<i>Viperidae, Australasian Elapidae</i>	Venom induced consumption coagulopathy (VICC)
Kallikrein (kininogenase) serine proteases	—	<i>Viperidae</i>	Hypotension
Kunitz-type proteinase inhibitors	Dendrotoxins	<i>Elapidae</i>	Inhibition of circulating serine proteases resulting in depolarizing neuromuscular block
L-amino oxidase	—	All	Programmed cell death (Apoptosis)
Natriuretic peptides	—	<i>Elapidae</i> : atrial-type and brain-type; <i>Viperidae</i> : C-type	Hypotension
Nerve growth factor	—	Many	Not known
Phospholipases A2	$\beta$ bungarotoxins	<i>Bungarus spp</i> (many phospholipases A2 in venoms of most snakes)	Presynaptic inhibition resulting in paralysis and destruction of nerve terminals, myotoxicity, hemolysis, inflammation, necrosis, platelet effects
Vascular endothelial growth factor (VEGF)	VEGF-homologous potent hypotensive factor	<i>Viperidae</i>	Endothelial damage, increased permeability resulting in third space loss, edema, hypotension

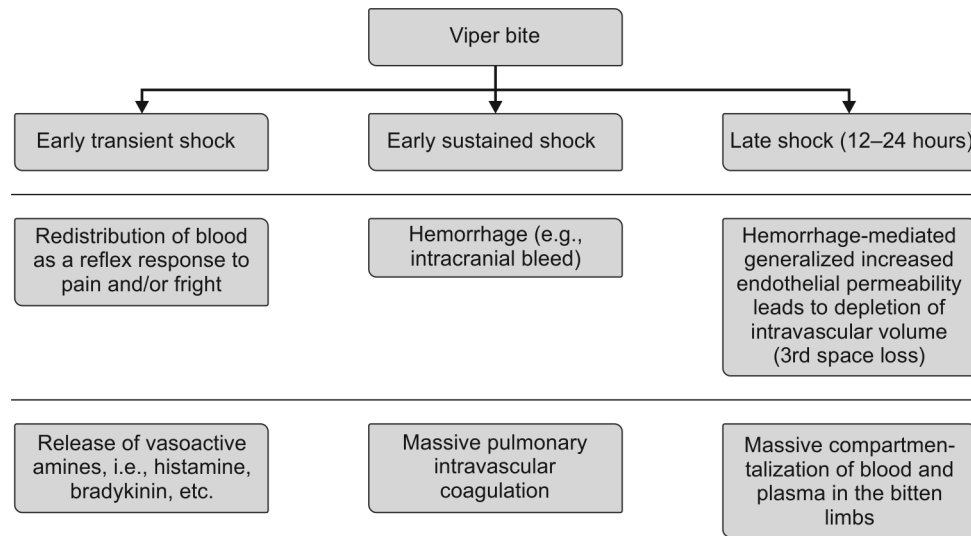

capillary leakage alone or along with a combination of acute bleeding induced hypovolemia. The clinical course of a viper bite may produce three kinds of shock (**Flow chart 1**). Severe envenomation may result to acute renal insufficiency as a result of hypovolemic shock due to vasodilation or bleeding, coagulopathy, rhabdomyolysis and direct nephrotoxicity of venom causing acute tubular necrosis. *Hemorrhagins* present in Russell's viper venom may cause acute hypopituitarism due to the hemorrhagic destruction of the pituitary. Viper and colubrids envenomation may produce clinical features of both thrombotic and hemorrhagic complications. The toxins in the venom may alter the coagulation pathway and the platelets function by different mechanisms, indicating the underlying basis for the clinical occurrence of thrombosis and hemorrhages in different parts of the human body.

muscles. Recovery of paralysis usually starts in the reverse order, and around 2 days is the median time taken for onset of recovery from respiratory failure. The subsequent pattern of involvement of descending paralysis is difficult to explain neurophysiologically.

### Locked-in Syndrome in Snakebite

In LIS, patient is conscious yet unable to communicate; the pupillary reflex is absent (internal ophthalmoplegia due to autonomic dysfunction). There are three kinds of LIS: *classic*, where even if the patient retains vertical eye movements and consciousness, he is afflicted with quadriplegia and anarthria. *Incomplete* LIS is similar to the *classic* type of LIS, except for the presence of voluntary movements in addition to vertical eye movement. In *total* LIS, except for the preserved consciousness there is a total

**Flow chart 1** Different types of viper bite-induced shock

### Neurological Complications

A snakebite victim may present with various neurotoxic features ranging from early morning neuromuscular syndrome to several cranial nerve palsies. These conditions are defined by different names like *locked-in syndrome* (LIS) in snakebite, brain stem reflex suppression, peripheral LIS and early morning snakebite syndrome. Single venom may lead to severe and complex neurological damage as it can present with both anticoagulant/procoagulant and neurotoxic effects. Reversal of paralysis by anti-venom is rendered improbable due to the high-affinity binding properties of neurotoxins. A rapid improvement in neurotoxicity occurs when the implicated toxins have a postsynaptic effect, e.g., cobra envenomation. Binding of  $\alpha$ -toxin (three-finger-fold polypeptide toxin) in the venom of black-necked spitting cobra, to the acetylcholine receptor has been shown to be reversible. The common krait is a nocturnally active snake with a painless bite; so many patients with neurological manifestations present to the emergency without history of snakebite.

Onset of paralysis after snake envenomation, i.e., the *time lag* is usually around 4–12 hours. The earliest clinical manifestation of paralysis is usually drooping of the upper eyelid (ptosis) followed by external ophthalmoplegia. The usual progression of paralysis but not necessarily in the following order is the involvement of muscles of palate, jaw, tongue, larynx, neck and muscles of deglutition. A complete quadriplegia and *locked-in* state can occur when the proximal limb muscles are involved earlier than distal

loss of power, immobility and inability to communicate. The most likely causes of LIS to be considered while evaluating patients are stroke, trauma or encephalitis involving ventral pons; however, it can also be caused by extensive damage of bilateral corticobulbar and corticospinal tracts in the cerebral peduncles. LIS can also be caused by other conditions such as severe Guillain-Barré syndrome, neuromuscular junction blockade (myasthenia gravis, toxins) (**Table 2**). Duration of LIS can range from 30 hours to 6 days. Key points are summarized in **Box 1**.

Locked-in syndrome in snakebite occurs due to neuromuscular paralysis of voluntary muscles, which in turn is caused by a neuromuscular transmission blockade (krait venom acts at presynaptic level while cobra venom acts at postsynaptic level) (**Fig. 2**). Irreversible binding of the toxin to presynaptic portion makes clinical recovery slow in krait envenomation and recovery occurs only after synthesis of new neuromuscular junctions and vesicles. Physicians should recognize the condition of *LIC* while managing the patients to prevent the dangerous error of diagnosing brain death. In the case of viper envenomation neuromuscular paralysis may also occur along with prolonged bleeding tendency (**Figs 3A to D**).

### Venom-induced Consumption Coagulopathy (VICC)

A procoagulant or consumption coagulopathy is the most common coagulopathy seen in snake envenomation. The diagnosis of disseminated intravascular coagulation (DIC) is problematic in

**Table 2** Differential diagnosis and causes and mechanisms of *locked-in syndrome (LIS)*

Cause	Mechanisms
Ischemic	Occlusion of the basilar artery, hypotensive or hypoxic events resulting in loss of blood supply
Hemorrhage	Hemorrhage or infiltration involving the pons
Traumatic	Contusion of brain stem, Dissection of vertebrobasilar axis system
Tumor	Involvement of ventral pons (primary or secondary tumor)
Metabolic (Na <sup>+</sup> disorders)	Central pontine myelinolysis (CPM)
Demyelination	Involving the ventral pons
Infectious	Infiltration of abscess involving the ventral pons, brain stem encephalitis (JE)

Abbreviation: JE, Japanese encephalitis

**BOX 1** Locked-in syndrome in snake envenomation

- The internal and external ophthalmoplegia can occur in snake envenomation.
- Supportive care should be continued until the effects of the venom wear off.
- In order to avoid misdiagnosis of brain death, confirmatory tests of brain death like cerebral angiography, electroencephalography, etc., should be considered.
- Treating physician should be aware of the locked-in syndrome in snakebite patients.

**Figure 2** Pre- and postsynaptic envenoming. Krait venom is also, like a cobra, strictly neurotoxic, it has no hemotoxic effect. Unlike the cobra, its venom enters the system and makes its way to the brain side of the neuromuscular junction. There a constituent element of the venom Phospholipase A2 destroys the synaptic vesicles. It is, therefore, primarily presynaptic in nature. This is the reason that krait victims take longer to recover. The body must grow more vesicles to replace the ones that have been destroyed. This results in an inability to produce acetylcholine and thus the signal from the brain cannot be transmitted across the synaptic gap. The diaphragm is unable to contract and the victim suffers respiratory failure

**Figures 3A to D** Neuroparalysis due to viper bite envenomation. (A) Local swelling; (B) Ptosis; (C) Prolonged 20-WBCT; and (D) Neck muscle weakness

snake envenomation because features of DIC such as an elevated D-dimer, prolonged prothrombin time, and low fibrinogen are always present in VICC, and thrombocytopenia is often related to VICC, as well. Few significant features of DIC, such as evidence of systemic microthrombi formation and end-organ failure are not characteristics of VICC. Patients with VICC may appear to be asymptomatic without any systemic features. The natural course of VICC differs from DIC with respect to rapid onset of coagulopathy within hours of the snake envenomation and resolution by 24–48 hours. VICC can either resolve spontaneously or after antivenom therapy over 24–48 hours.

The pathogenesis of activation of coagulation is different in VICC from DIC. In the case of DIC, activation of the coagulation leading to the formation of thrombin and is mediated by the tissue factor/factor VIIa pathway, which is not balanced by anticoagulant system due to impairment in the major anticoagulant pathways. In addition, there may be suppression of the fibrinolytic system leading to impairment of the fibrin removal in contrast to VICC, wherein these series of events does not occur. In VICC, the activation of coagulation is usually due to the effect of one of the procoagulant toxin present in the snake venom at one point of the pathway in the coagulation and not via the activation of tissue factor/factor VIIa pathway. Depending on the action of the toxin on the pathway, the resultant coagulopathy clinically can range from mild, partial or complete consumption of fibrinogen alone seen with thrombin-like-enzymes in vipers venom, to more severe coagulopathy, seen with prothrombin activators present in elapids venom, factor X activators in Russell's viper venom that the cause severe depletion of fibrinogen, factor V, factor VIII and activation of factor X respectively.

Venom-induced consumption coagulopathy differs from DIC in the following aspects: there is no microvascular thrombosis, no obvious fibrin formation and resultant end-organ damage or organ failure. Complication in VICC is usually due to bleeding, whereas DIC is characterized by classic fibrin formations, microvascular thrombosis that result in end-organ failures, as well as bleeding complications. Metalloproteinase prothrombin activators found in snake venom activate the coagulation pathway and concurrently cause injury to the blood vessel, resulting in the risk of bleeding manifestation in VICC.

The current available consensus guideline criteria for diagnosis of DIC if applied to VICC will often match most of the criteria and suggest overt DIC in a given patient. However, VICC

is clearly different based on the current understanding of the pathophysiology of activation of coagulation, the time course, and the prognosis. These are the main reason for the long-time belief that snakebite can cause DIC. Therefore, it is important that the terminology *VICC* be used to clarify the clinical syndrome requiring different treatment approaches.

Coagulopathy seen in snake envenomation is usually due to the direct effect of toxins present in snake venom. Using specific antivenom to remove these toxins should allow the coagulopathy to return to normal homeostasis. Nevertheless, the antivenom can neither repair the complications caused by coagulopathy like end organ failure nor can it stop any secondary phenomena activated during coagulopathy like hyperfibrinolysis. Hence, it is essential to administer the appropriate antivenom as early as possible in sufficient quantity, once coagulopathy is detected, and any further supplementary doses of antivenom if the clinical condition warrants the same. It is of equal importance to avoid other therapies like heparin, warfarin, fresh frozen plasma (FFP), cryoprecipitate that may further worsen the condition of coagulopathy. Heparin will not *switch off* the pathologic process of *VICC*, so it is of no help, rather it may induce its degree of pathologic changes in the clotting process. The addition of FFP or cryoprecipitate may only complicate things, especially with procoagulant unless the antivenom has removed all the venom.

### Snakebite Induced Thrombotic Microangiopathy (TMA)

Clinical syndromes of thrombotic microangiopathy have been reported in patients with snake envenomation and are characterized by thrombocytopenia, acute renal failure and hematological abnormality suggestive of microangiopathic hemolytic anemia. The exact mechanism of snakebite associated TMA remains unclear and proper definition of this condition is still not available. The TMA appears to occur in conjunction with *VICC* of not only certain snake species, but also in several snake species including vipers and elapids. Though features are consistent with TMA, it progresses despite normalization of coagulopathy, suggesting a different but related process in the pathogenesis. The presence of overlapping clinical features in *VICC* and TMA in snake envenoming is the likely reason for the mistaken idea that snake envenomation is the cause of DIC.

The treatment of snake envenomation associated TMA remains controversial. Recommendations for the administration of FFP, cryoprecipitate and plasmapheresis remain unproven and

are associated with worsening clinical condition. In most of the patients improved with supportive care and in many cases it is not recognized as such.

### Acute Kidney Injury

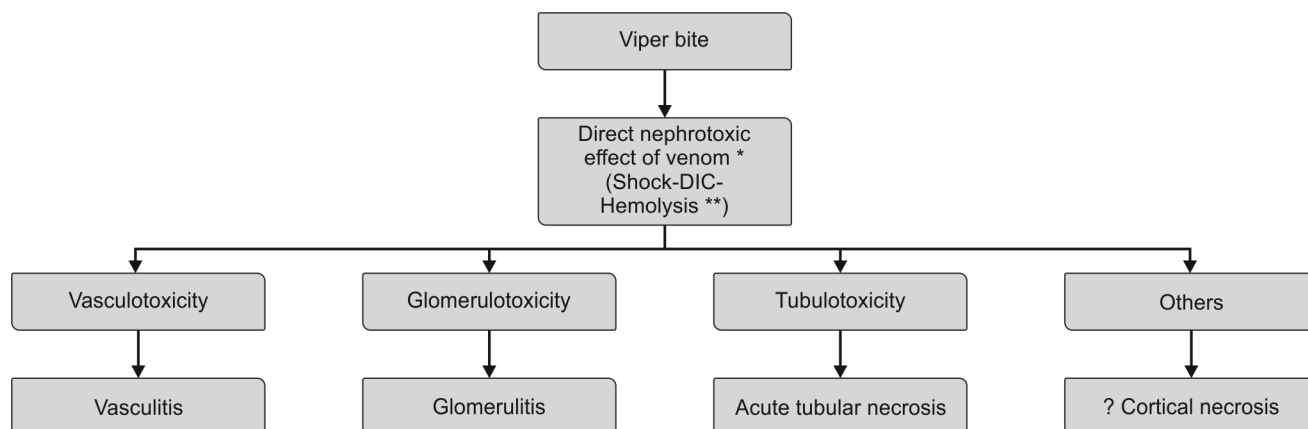

In many cases of envenomation due to various snake species, renal involvement has been reported. However, the most severe type, acute renal failure, is mainly seen in viper envenomation (**Flow chart 2**). In India, this is usually seen in most common viper species of Russell's viper and the Saw-scaled viper envenomation. The frequency of snake envenomation associated acute renal failure has been reported as 3–32% in India, 1.2% in Thailand, and as high as 40% in Myanmar. A proposed mechanism of renal injury is venom-induced cellular injury through enzymes, polypeptide and different cytokines. Myotoxic or hemotoxic snakes cause renal failure and are responsible for the following complications—rhabdomyolysis, intravascular hemolysis, DIC or bleeding.

Renal failure can occur as early as an hour to as late as days after envenomation, with evidence of the rapid rise in blood urea and serum creatinine. Nonoliguric renal failure is not uncommon and can persist for an average duration of up to 3 weeks. The histopathology of snakebite associated renal failure consists of predominantly acute tubular necrosis (ATN) in 73% and acute interstitial nephritis (AIN) in 5–15% of patients while reported changes in glomerulus pathology are rare. Metalloproteases and phospholipase A2 may be responsible for degeneration and necrosis of tubular epithelial cells and interstitial edema and cellular infiltration. Immune-mediated mechanisms play a diminutive role in the pathogenesis of renal failure. However, in Russell's viper envenomation, diffuse AIN disproportionate to tubular cell degeneration has rarely been reported as a mechanism of renal failure. Though many factors can contribute to the development of AIN, direct toxicity of snake venom has been postulated in the development of the interstitial inflammation via production of cytokines and adhesion molecules.

The exact role of direct nephrotoxicity by snake venom remains unclear, but hypersensitivity reaction to the venom or antivenom protein has rarely been found to cause the acute renal failure. The conclusion that antivenom protein is the cause of renal failure needs to be proven. The histopathological finding of AIN is correlated with poor prognosis for development chronic kidney disease (CKD) during long-term follow-up.

Independent risk factors associated with renal failure and dialysis requirement are, delayed administration of an adequate

**Flow chart 2** Mechanisms of viper bite-induced renal failure

\* Major contributing factor in the pathogenesis of viper bite-induced renal failure.

\*\* Contributing factor in only few cases. Shock may be a key predisposing factor in the cortical necrosis.

dose of ASV, presence of cellulitis, and bite during the winter months, low platelet count, bleeding, intravascular hemolysis and hypotension at presentation. Management of snakebite induced renal failure is primarily of supportive care along with timely administration of ASV. Rather than being concentrated in referral hospitals, ASV should be made available in all emergency and primary health centers near local communities.

### Compartment Syndrome

Envenomation of a limb can lead to cutaneous necrosis, compartment syndrome and even necrotizing fasciitis. Compartment syndrome in snakebite is uncommon and it usually affects the upper limb. The principal local effect of venom is edema, which occurs within 2 hours after a bite and intensifies during the following 3 days. Swelling and vasoconstriction lead to ischemia and compromise the vitality of the limb. The six symptoms/signs that point towards compartment syndrome are pain on passive stretching, disproportionate pain, pulselessness, pallor, paresthesia and paralysis. However, presence of arterial pulses does not exclude intracompartmental ischemia. The most reliable test in suspected cases is to measure intracompartmental pressure directly through a cannula introduced into the compartment and connected to a pressure transducer or manometer. McQueen and Court-Brow consider that a difference of 30 mm Hg between diastolic and compartment pressure is the threshold of fasciotomy. Early treatment with antivenom remains the best way of preventing irreversible muscle damage.

### MANAGEMENT

The steps involved in the management of snake envenomation victims are: (1) First aid treatment practice(s) (2) Transport of the victim to a nearby health-care facility (3) Rapid clinical assessment and resuscitation of the victim (4) Detailed clinical assessment and identification of snake species (5) Diagnosis and investigations or laboratory tests (6) ASV administration (7) Observing and documenting the response to ASV (8) Decision regarding follow-up dose(s) of ASV (9) Additional supportive care (10) Treatment of bite area (11) Recovery (12) Management of chronic complications if any. Immediate treatment of snakebite in the field consists of safe identification of the snake species whenever possible and early transports of patients to the nearest health-care facility with ASV administration. Risk factors for poor outcome are listed in **Box 2**.

#### BOX 2 Risk factors for poor outcome (death or major disability)

- Age (younger the age: adjusted OR 0.85; 95% CI 0.7–0.9)\*
- Walking for > 1 km after the bite (adjusted OR 57; 95% CI 4.2–78.2)\*
- Hemoglobin ≤ 10 g/dL at admission (adjusted OR 6.2; 95% CI 2–18.2)\*
- Species of snake (cobra)
- Vomiting

\*Independent risk factors for poor outcome

### First Aid

The first aid treatment aims to (1) to delay systemic absorption of venom (2) to preserve life and prevent complications before medical care is given (3) to control distressing or dangerous early symptoms of envenoming (4) arrange the transport of the patient where medical care is available including administration of ASV (5) to do *NO HARM*. First-aid treatment in children can be performed by anyone else who is present and able.

*Unhelpful first-aid treatment* Traditional healers undertake the immediate treatment of snakebite in most of the developing countries. These traditional, accessible, available and affordable first-aid methods are mostly useless and dangerous. The various

healing methods include: efforts to suck the venom out of the wound, tying tourniquets (tight bands) around the limb, making local incisions or pricks/punctures (tattooing) at the site of the bite or in the bitten limb, use of (black) snake stones, topical instillation or application of chemicals, herbs or ice packs, electric shock (**Fig. 4**). Traditional treatments by local people should not be allowed to do harm or delay medical treatment. Traditional treatment distorts the clinical picture and delays presentation, and can trigger an infection, bleeding, gangrene, and other complications including death.

### Reliable Technique: Pressure Immobilization Method

Snakebite victims' first choice of first aid is resort to tying tight bands (tourniquets) around their limbs. The tourniquets are ineffective in retarding venom flow. There is also the risk of ischemic damage to the victim due to an increase in the necrotic action of the venom. In the eventual release of the tourniquet, there is a danger of neurotoxic blockage and clotting. Early transport to medical care facility is advisable and harmful traditional treatments should be ignored. In the late 1970s the Pressure Immobilization Method (PIM) was developed in Australia as a reliable technique to prevent venom flow into the system (**Figs 5A to E**).

#### Pressure Immobilization Method

Until possibility of a bite by a neurotoxic elapid eliminated, bandaging the bitten limb at a pressure of about 50–70 mm Hg and immobilizing it with a splint (pressure immobilization) or pressure pad is required at the bite site in a similar way as is done for a sprain. PIM obstructs the lymphatic and venous drainage, which in turn delays absorption of large molecular weight neurotoxins into the system, without the dangerous use of tight tourniquets. The clinical efficiency of these methods is yet to be sufficiently examined. In a simulated environment emergency room physicians and lay people failed to apply the method correctly as the required bandage pressure varied between lower and upper limbs. The technique also required complete immobilization. Walking for more than 10 min invalidated the effect of the bandage, even if it was applied in the correct range of pressure.

### Do it R.I.G.H.T.

Both PIM and tourniquets require the use of equipment affecting the feasibility in developing countries. Moreover, in a primary care setting, practical application of pressure immobilization has been difficult to teach; these are not recommended for use in the National Protocol for Management of snakebite in children. As per the recommendations by National Protocol, the first aid treatment is based around the mnemonic: *Do it R.I.G.H.T* (**Box 3**). Ideally, tight bands, bandages and ligatures if applied, should not be released until the patient has reached the hospital, where resuscitation facilities and ASV are available. Investigations of other methods like the early administration of ASV, early transport of the victim to the health-care facility in rural setting by volunteer motorcyclists, and education of paramedics and ambulance crews about basic life support are potential areas of future study.

### Identifying the Species of Envenoming Snakes

The usual reports of unidentified snakebites tend to ignore the vast interspecies diversity of snake venom actions. Attempts should be made to discourage the capture or killing of the snakes responsible for the bite. It is both dangerous and ecologically destructive. The captive snake can be wrongly identified, leading to unsuitable treatment. Herpetologists have been known to make serious errors with respect to recognition of snake species. It is also unreliable

**Figure 4** Inapplicable first aid treatments. *DO NO HARM* during first aid

**Figures 5A to E** Pressure immobilization method. (A to C) Commencing distal to bite the site, apply the bandage as tightly as binding a sprained ankle, enveloping the bite site and extending to above major joint; (D and E) Apply splint to prevent movement of a limb, thereby preventing muscle use and lymphatic flow

**BOX 3 Do it R.I.G.H.T.**

- *R.* = Reassure the patient  
*Rationale:* Seventy percent of snakebites are from nonvenomous species. Only 50% of snakebites by venomous species really envenomate the patient.
- *I.* = Immobilize the patient as is done for a fractured limb  
*Rationale:* We can carry children. Bandages or cloth should be used to hold the splints in place, and not to block blood supply or apply pressure. Use of tight ligatures to apply any kind of compression, is dangerous and they do not work!
- *G.H.* = Get to Hospital immediately  
*Rationale:* There is *NO PROVEN* benefit in the treatment of snakebite with the use of traditional remedies.
- *T.* = The doctor should be briefed about any systemic symptoms such as ptosis that manifest on the way to hospital.  
*Rationale:* To prepare the treatment plan.

to try to identify the species following descriptions by victims or their escorts or from photos of snakes. A more reliable method in snakebite identification is to differentiate the various *clinical syndromes* of snake envenoming by a detailed analysis of a series of clinical signs and symptoms (**Flow chart 3**).

### Diagnosis and Testing

Bite marks do not help in ascertaining if the snake was venomous or nonvenomous. Venomous snake species have multiple sets of fangs, and nonvenomous snake species can leave puncture marks from enlarged teeth, which appear to be fang-like. Based on the presence or absence thereof, the following features formed the basis of *snake envenomation diagnosis*: snake bite history, bite marks, local manifestations—swelling and pain at the bite site, or systemic manifestations—features of neurotoxicity or spontaneous bleeding and/or if the dead snake was brought in for identification.

#### 20-minute Whole Blood Clotting Test (20-WBCT)

It is an informative and useful bedside standard test for coagulopathy in the management of snake envenomation. This vitally needs a *new, clean, and dry test tube* and requires 2 mL of fresh venous blood, which is then left untouched for about 20 min, before being gently tilted once. In the case of hypofibrinogenemia (*incoagulable blood*), the blood is still liquid (unclotted) and runs out. Incoagulable blood is an undisputed diagnostic of a viper bite in India and certainly removes any doubt of an elapid bite. The wall of the test tube or vessel may not stimulate clotting of the blood

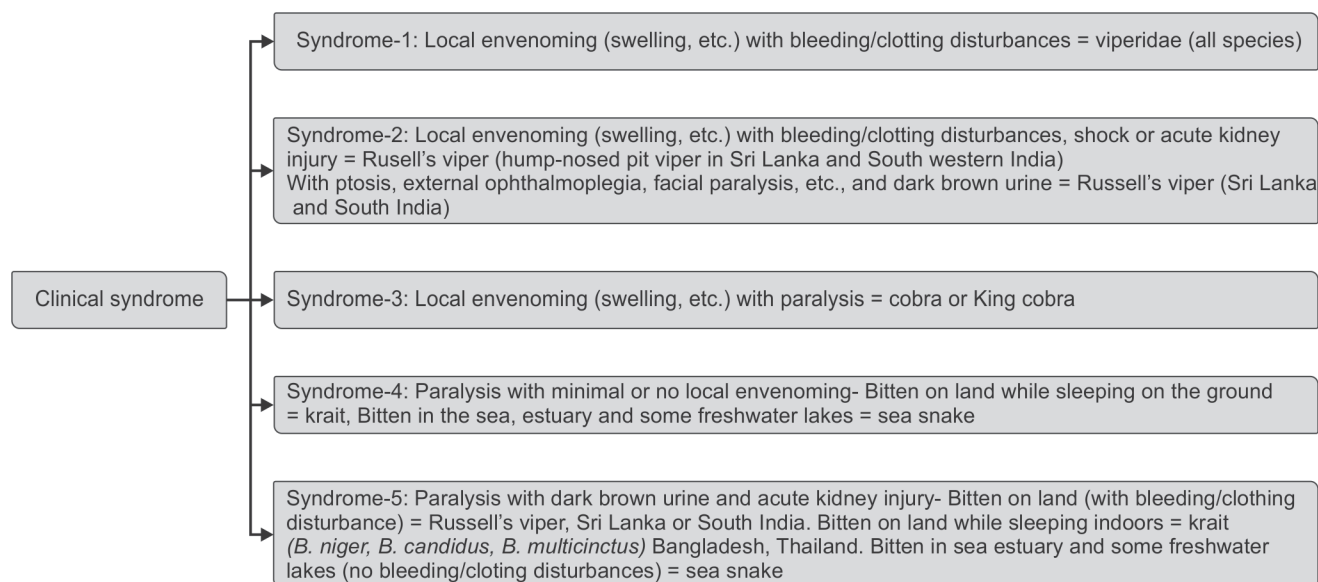

sample (surface activation of factor XI—Hageman factor), if it is not made of ordinary glass or detergent has been used as a cleansing agent, and hence, the test will be invalid. In the case of doubt, it is best to redo the test in duplicate, along with *control* element (e.g., a blood sample of a healthy relative).

### Other Tests

**Hematological abnormalities** Hemoconcentration (a transient increase of hemoglobin (Hb) is a result of a generalized surge in capillary permeability (e.g., in Russell's viper bite). Often, decreased Hb levels result from blood loss or intravascular hemolysis if it is a case of Indian and Sri Lankan Russell's viper bite. Snake bite victims of vipers and Australian elapids may show a decrease in platelet count. Early neutrophil leukocytosis reflects evidence of systemic envenoming by any species. In the case of microangiopathic hemolysis, fragmented red cells (helmet cell, schistocytes) are seen on blood film. Gross hemoglobinemia or myoglobinemia results in a pinkish or brownish plasma/serum.

**Biochemical abnormalities** In case of severe local tissue damage or, generalized muscle damage in particular (sea snake, South Indian and Sri Lankan Russell's viper bites), elevated levels of muscle enzymes (creatine kinase, aldolase) and aminotransferases are found. Massive blood extravasation leads to elevated bilirubin. Snake envenomation by a Russell's viper, hump-nosed viper and sea snake causes acute renal failure with raised levels of creatinine, potassium, and urea or blood urea nitrogen. Early hyperkalemia follows extensive rhabdomyolysis in sea snakebites.

**Flow chart 3** Approach of snakebite patients based on clinical syndrome

## Antisnake Venom

This method of envenoming treatment was first introduced in Saigon in the 1890s by Albert Calmette at the Institute Pasteur and was widely accepted in clinical practice without formal clinical trials. A mule or donkey or horse (equine) or sheep (ovine) is immunized with the venom of one or more snake species. Immunoglobulin [usually pepsin-refined Fab2 fragments of whole IgG] purified from the plasma of these animals is used to obtain antivenom. Antivenom raised against a specific snake species is called *Specific* antivenom. Hence, it contains specific antibodies to neutralize the venom of that particular snake or its closely related species (para-specific neutralization).

**Antisnake venom administration criteria** Antisnake venom treatment should be administered as soon as the following symptoms present:

- The 20-WBCT suggesting a coagulopathy, symptoms of spontaneous bleeding or neurological impairment such as ptosis. Even when symptoms have persisted for several days or more in the case of hemostatic abnormalities, ASV may reverse systemic envenoming. If symptoms of coagulopathy persist, it is appropriate to give ASV.
- Local symptoms such as rapid swelling across a joint including half the bitten limb even in the absence of a tourniquet. When the swelling persists 1 hour after the removal of the tourniquet, it should be attributed to venom release rather as an effect of the tourniquet
- Persistent abdominal pain and vomiting.

Whether local administration of ASV can prevent local tissue necrosis remains uncertain. There is limited evidence available to confirm that for ASV to be useful it is required to be administered in the initial hours after the bite; however, once there is an indication, treatment with ASV should not be delayed.

**Antisnake venom doses and administration** A frequent topic of debate has been the initial dose of ASV to be administered to a patient. The first bite of a Russell's viper can inject an average of 63 mg (SD 7 mg) of venom. Taking into account the average dose of injected venom, the initial dose has been calculated to neutralize its effect. This method aims to cover the majority of victims with the initial dose. 6 mg of Russell's viper venom can be neutralized by a single vial of polyvalent ASV; therefore, both children and adults require an initial dose of 8–10 vials. If the range of venom injected falls between 5 mg and 147 mg, it requires a maximum ASV dose of around 25 vials. Suitable levels of ASV in children (higher level—because of body mass, lower level—to prevent adverse reaction) are yet to be ascertained.

Reconstituted ASV is diluted in 5–10 mL/kg bodyweight of normal saline or 5% dextrose (5D) or Ringer lactate (RL) solution and should be administered over 1 hour at a constant rate with hemodynamic monitoring. The degree of severe systemic hypersensitivity reactions is not affected by the slow (over 120 min) or rapid (over 20 min) infusion of ASV. Administering each dose over a long period has no benefit, while prolonging the time before ASV can neutralize the venom proves to be counter-intuitive.

**Adverse reactions to antisnake venom** The primary reasons for not administering ASV in peripheral hospitals/dispensary are the adverse reactions to ASV (pyrogenic or anaphylactic). Most primary care doctors are reluctant to treat snakebite victims; due

to possible life-threatening reactions. Doctors should not shy away from treating snakebite victims as early treatment with appropriate drugs can overcome these reactions. Positive outcomes can be realized with early intervention against these actions.

Antisnake venom should be discontinued and adrenaline 0.01 mg/kg body weight intramuscular should be given if any of following *signs* appears: nausea, vomiting, diarrhea, urticaria, itching, and fever, shaking chills, abdominal cramps, tachycardia, hypotension, bronchospasm and angioedema. In addition, 2 mg/kg of hydrocortisone IV and a dose of intravenous antihistaminic drug should be administered to provide protection against anaphylactic reactions. After being given ASV, usually more than 10% of patients develop a reaction. It can occur within a few hours (called as an early reaction) or even after 5 days or more (called as the late reaction). After sufficient recovery of the patient, a slow restart (10–15 min) of ASV can be made under close observation of the patient. Typical drip rate can be resumed later. ASV test dose does not have any role in predicting anaphylactic or late serum reaction and may presensitize the patient to the protein.

## Anticholinesterase Drugs

Patients with neurotoxic envenoming, specifically cobra bites can experience a potentially useful yet variable effect from anticholinesterase drugs. Every patient with neurotoxic envenoming should be considered for a trial of anticholinesterase. However, this should not delay ASV treatment. Atropine sulphate (50 µg/kg) is administered through an intravenous injection followed by 0.04 mg/kg of neostigmine bromide by an intramuscular injection. Even though the short-acting edrophonium chloride (Tensilon) is suitable for this test, its nonavailability is a limiting factor; a dose of 0.25 mg/kg through a slow intravenous injection is used to administer the drug. The patient is observed for signs of improved neuromuscular transmission over the next 10–20 min (edrophonium) or 30–60 min (neostigmine). Ventilator capacity (peak flow, FEV-1 or maximum expiratory pressure) may improve and ptosis may withdraw. Patients with a positive response can be continued on 0.01–0.04 mg/kg dose of neostigmine, every 2–4 hours for 24 hours, by intravenous, intramuscular, or subcutaneous injection along with atropine to inhibit muscarinic side effects.

## Repeat Doses of ASV

In antihemostatic bites, after the initial dose (over 1 hour) has been administered, no further ASV is required for the next 6 hours. The liver requires the time to restore the clotting factors. The following factors are considered for a repeat dose of ASV (1) Persistence or recurrence of bleeding (after 1–2 hours) or blood incoagulability (after 6 hours) (2) Reappearing or deteriorating cardiovascular or neurotoxic signs after 1–2 hours.

## Supportive Care

Antisnake venom treatment can be relied upon to neutralize the free circulating venom, prevent further progress of envenoming and allow for recovery. Nevertheless, these processes do take time, and envenomed patient may require further life support systems such as assisted ventilation, treatment of shock, and renal dialysis until the afflicted tissues and organs have sufficient recovery time.

### IN A NUTSHELL

1. Snake envenomations are an important cause of mortality, particularly in rural areas.
2. The important venomous snakes in India are common cobra (*Naja naja*), Russell's viper (*Daboia russelii*), saw-scaled viper (*Echis carinatus*) and common krait (*Bungarus caeruleus*).
3. The composition of the venom is species-specific, i.e., neurotoxins predominate in the venom of elapids, while cytotoxic and anticoagulant/procoagulant substances are found in the venom of vipers and colubrids.
4. Neurotoxic features of snakebite vary from early morning neuromuscular paralysis to several cranial nerve palsies. In addition, there may be brain stem reflex suppression and LIS.
5. The most common coagulopathy associated with snake envenoming is a procoagulant or consumption coagulopathy; usual manifestation is spontaneous bleeding.
6. Initiation of appropriate first aid is important; at the same time harmful practices should be discouraged.
7. In India, ASV is polyvalent antivenom effective against *Naja naja*, *Bungarus caeruleus*, *Daboia russelii* and *Echis carinatus*.
8. Antisnake venom should be given only to patients in whom its benefits are considered likely to exceed its risks.
9. The dose of antivenom is same for children and adults; children need relatively higher doses for their body size.
10. Patients with neurotoxic envenoming, specifically cobra bites may benefit from anticholinesterase drugs such as neostigmine.

## Chapter 9.7

# Scorpion Sting

S Mahadevan, R Ramesh Kumar

Scorpion sting envenomation in children is a life-threatening medical emergency. Children are at a higher risk of severe envenomation and death due to myocardial involvement, pulmonary edema, and neurological complications as compared to adults.

## EPIDEMIOLOGY

Worldwide, more than 1.2 million scorpion stings and 30,000 deaths are reported annually. In India, Saudi Arabia and South Africa, the reported case fatality rate of children hospitalized with scorpion sting ranges from 3% to 22%. Over 1,050 species of scorpions are known to exist worldwide. Approximately 50 species of scorpions are venomous and are responsible for clinical presentation in humans. These venomous species are included in the genera of *Centruroides*, *Buthus*, *Androctonus*, *Parabuthus*, *Leiurus*, *Mesobuthus*, *Tityus* and *Hemiscorpius*. In India, out of the 86 scorpion species, the only poisonous scorpions of any medical importance are *Hottentotta tamulus* and *Palamnaeus swammerdami*. *Hottentotta tamulus* (also named as *Mesobuthus tamulus*), the Indian red scorpion (also called as Eastern Indian scorpion), is responsible for most deaths, most of which are preventable with appropriate treatment (Figs 1A and B).

## DISTRIBUTION AND HABITAT

In India, scorpions are usually found to habitat dry, warm regions, with a primary species concentrated in coastal and rural parts with rich red soil. The scorpions usually inhabit dark sheltered places such as crevices in the walls, under rocks, bricks and logs, in dry paddy husks, under loose tree barks, behind furniture and inside clothing and shoes. They are nocturnal in habit, remaining hidden in the daytime and emerging at night to feed; this explains why maximum human stings are reported during the night.

In the summer, there is a drastic increase in scorpion stings. Scorpion stings are primarily a result of accidental encounters. If trapped or roughly handled, scorpions are likely to use their stings. Envenomation in scorpion sting does not always happen as a scorpion can control its ejaculation. Hence, a sting can be partial, total, or nonexistent.

## PATHOPHYSIOLOGY

### Composition of the Scorpion Venom

Scorpion venom is a heterogeneous mixture of short neurotoxic peptides with significant variation between different species. The neurotoxins are *species-specific* as well as *target-specific*—each one targeting the ion channels of a particular kind of animal—some are more effective against insects, some lethal to molluscs and yet others may target mammalian nerve cells. The venom also contains histamine, histamine-releasing factor, serotonin, hyaluronidase, certain enzymes, enzyme inhibitors, salts, peptides, nucleotides and free amino acids. Venom is usually deposited in the skin, deep into the subcutaneous tissue; absorption is complete in around 7–8 hours while 70% venom concentration in blood is reached within 15 minutes.

### Effect of the Venom Toxins on Autonomic Function

The venom alters voltage-dependent ion channels. The sodium channel is affected by beta (of *Centruroides* spp) and alpha (of *Buthus* spp) toxins. The toxins *tityus* and scyllatoxin, and charybdotoxin of *Leiurus* species act mainly on potassium channels. The toxin inhibits the inactivation of the ion channels and result in persistent neuronal excitation and an autonomic storm. The effects of the toxins on the calcium and potassium channels may be less important in humans.

The alpha toxins stimulate the release of epinephrine, norepinephrine, and vasoactive peptides such as endothelin and neuropeptide Y; these are responsible for the development of myocardial dysfunction, hypertension, pulmonary edema, tachycardia and cool extremities. In addition, hyperkalemia, free fatty acids, hyperglycemia, and free radicals accumulation injurious to myocardium occur. The venom of an Indian red scorpion causes acute myocarditis, cardiac sarcolemmal defects, and depletion of glycogen content of heart, and liver and skeletal muscles. Electron microscope studies have shown contraction band necrosis with ruptured and hypercontraction sarcomeres due to the excessive catecholamine similar to the one seen in the pheochromocytoma. The effect on the parasympathetic function may contribute the respiratory impairment; though as compared to the sympathetic effects, these are less prominent.

Increase in leukocyte count within an hour of sting and rise in renin, angiotensin II, cardiac enzyme, platelet activating factors, cytokines, serum potassium, hyperglycemia, urine and serum catecholamine, serum amylase and reduction in insulin level may occur.

**Figures 1A and B** Scorpions are arachnids belonging to the Phylum: Arthropoda; Class: Arachnida and Order: Scorpionidae. (A) Indian red scorpion (*Mesobuthus tamulus*); (B) Black scorpion (*Palamneus gravimanus*)

## Effects of the Venom on Other Organs

Scorpion sting envenomation can cause changes in coagulation profile and may lead to acute disseminated intravascular coagulation (DIC). Seizures and encephalopathy in some children are observed due to the neurotoxicity. The central nervous system (CNS) manifestations may be due to acute rise in blood pressure due to sympathetic stimulation, rupture of unprotected perforating arteries, intracerebral hemorrhage and cerebral infarction due to DIC. It has been proposed that the coagulopathy also contributes to acute lung injury and increased alveolocapillary membrane permeability.

Local inflammation is unusual in Indian red scorpion envenomation. The Iranian yellow scorpion (*Buthus compsobuthus* and *Hemiscorpius lepturus*) invokes varied skin reactions, namely, edema, erythema, severe necrosis and lymphangitis. This phenomenon could be attributed to the polypeptide variations of different venom. Victims of yellow scorpion sting may show signs of severe hemolysis and secondary renal failure. Venom of scorpion species *Tityus trinitatis* in Trinidad causes acute pancreatitis through the intrapancreatic conversion of trypsinogen to trypsin.

Envenomation caused by scorpion species *Tityus serrulatus* triggers a systemic inflammatory response like syndrome with an increase in levels of interleukin-6, IL-1a and interferon-gamma. In scorpion-envenomed children, there is a correlation between cytokines levels and clinical severity.

## CLINICAL MANIFESTATIONS

The varied clinical effects of envenomation depend upon scorpion species, amount of injected venom and lethal dose of the venom. Species-specific variations in clinical manifestations of scorpion envenomation in different parts of the world are given in **Table 1**. In the case of multiple stings by the same scorpion, severity is greater in the first victim as compared to the following victims. The scorpions' size and age, season of the sting and the time between sting and hospitalization contribute to the severity of envenoming.

The clinical features following envenomation by the Indian red scorpion are predominantly due to autonomic excitation that adversely affects the cardiovascular system. The picture may range from mild sympathetic stimulation of the heart to life-threatening complications such as myocarditis and pulmonary edema. Children due to their low bodyweight show a high severity of symptoms and develop more rapid progression. Envenomation can be graded into four categories based on the clinical manifestations during hospitalization and severity (**Table 2**).

### Local Manifestations

Following a sting, the patient experiences an unbearable radiating pain from sting site usually the toes and fingers. In children, there is the sudden onset of inconsolable, incessant crying. There is mild sweating, rise in blood pressure and transient bradycardia due to pain (**Table 3**).

### Systemic Manifestations

Systemic features following scorpion sting are due to autonomic storm—a massive release of catecholamines from the adrenergic and cholinergic neurons and the adrenal medulla into the circulation. There is an initial transient cholinergic phase that merges imperceptibly into a more sustained adrenergic phase (**Tables 4 and 5; Flow chart 1**).

Myocardial injury may be heralded by onset of excessive vomiting and palmoplantar sweating. Clinical indicators of myocardial involvement include marked tachycardia, S3 gallop rhythm, other rhythm disturbances, cold extremities and a fall in blood pressure. Early stages may be missed clinically, but for the electrocardiogram (ECG) variations like tall T waves and

**Table 1** Species-specific variations in clinical manifestations of scorpion envenomation in different parts of the world

Region	Important species	Dominant clinical picture
India	<i>Hottentotta tamulus</i> <i>Palamneus swammerdami</i>	Cardiovascular
Israel	<i>Buthus occitanus</i>	Cardiovascular
Brazil	<i>Tityus serrulatus</i> <i>Tityus bahiensis</i>	Cardiovascular
Mexico	<i>Centruroides</i>	Cardiovascular
Saudi Arabia	<i>Centruroides limpidus</i> <i>Centruroides noxius</i> <i>Centruroides suffusus</i>	Cardiovascular
Iran	<i>Hemiscorpius lepturus</i> <i>Mesobuthus eupeus</i> <i>Odontobuthus doriae</i>	Tissue necrosis Hemolysis Renal failure
South Africa	<i>Androctonus crassicauda</i>	Neurological
USA	<i>Centruroides exilicauda</i>	Neurological
Trinidad	<i>Tityus trinitatis</i>	Acute pancreatitis

**Table 2** Grading of scorpion sting envenomation at the time of arrival to the hospital

Grade	Clinical description
Grade 1	Local manifestation: Severe, <i>excruciating local pain</i> at the sting site radiating along the corresponding dermatomes, mild local edema with sweating at the sting site, <i>without systemic involvement</i>
Grade 2	Autonomic storm: Signs and symptoms of <i>autonomic storm</i> characterized by acetylcholine excess or parasympathetic stimulation (vomiting, profuse sweating from all over body, <i>ropy salivation</i> , bradycardia, premature ventricular contraction, hypotension, <i>priapism in boys</i> ) and sympathetic stimulation (hypertension with blood pressure more than the normal limits for the age, tachycardia with heart rate more than the normal limits for the age, cold extremities, transient systolic murmur)
Grade 3	Cold extremities, tachycardia, hypotension or hypertension with <i>pulmonary edema</i> (respiratory rate more than the normal upper limit for the age, basal crepitations or crackles in lungs)
Grade 4	Tachycardia, hypotension with or without pulmonary edema with warm extremities ( <i>warm shock</i> )

ST segment elevation. Mild envenoming cases show symptoms of severe vasoconstriction and hypertension. Predominant left ventricular dysfunction along with normal systemic vascular resistance can cause severe hypotension or pulmonary edema. Irreversible vasodilatation and myocardial dysfunction cause warm shock with or without pulmonary edema. Reduced left ventricular compliance, and an increase in impedance to left ventricular emptying cause the myocardial dysfunction, and pulmonary edema.

### Pulmonary Edema

Within 30 minutes of the sting, pulmonary edema develops with severe hypertension; development after 36 hours of sting can be seen with hypotension and tachycardia. It is clinically characterized by acute onset of cold extremities, sudden onset of intractable cough, dyspnea, tachycardia, systolic murmur, gallop, bilateral crepitations and low volume, fast thready pulse. In a few cases, it develops later, after an initial phase of apparent recovery. In the initial stages, pulmonary edema may be subclinical and detectable only with a chest X-ray. A sudden onset of massive

**Table 3** Local manifestation of scorpion sting

1. Mechanism	Serotonin, bradykinin and substance-P present in the scorpion venom have been implicated as causative agents of the pain
2. TAP sign	Sudden tap at and around the site of sting induces severe pain and withdrawal. It is a diagnostic sign of scorpion sting and is not usually reported by most the patients
3. Clinical importance	<ul style="list-style-type: none"> <li>Severe pain at the sting site without evidence of systemic involvement indicative of <i>benign or dry sting</i></li> <li>Whenever local pain was severe, there was often no further progression of symptoms</li> <li>There is little or no reaction at sting site. Presence of edema and signs of inflammation at the sting site blunt the sodium channel blocker action of Lidocaine administration</li> <li>Because of vasoconstriction due to release of catecholamine, pain conduction may be blunted, and it is tolerable or mild in nature. It will mask the clinical severity and presentation</li> </ul>
4. Prognostic importance	Reappearance of severe pain along with clinical improvement of peripheral circulation indicative of recovery of sting envenomation

**Table 4** Systemic manifestations of scorpion sting—due to cholinergic stimulation

Symptoms and signs	Clinical manifestation and implication
Vomiting	<ul style="list-style-type: none"> <li>Mechanism: Vomiting is due to serotonin content of venom</li> <li>Transient projectile usually vomiting due to autonomic storm</li> <li>Often seen in envenomation of <i>Mesobuthus tamulus</i> (India), <i>Androctonus crassicauda</i> and <i>Leiurus quinquestriatus</i> (Saudi Arabia, Israel), <i>Tityus serrulatus</i> (Brazil), <i>Centruroides</i> (Mexico)</li> </ul>
Cholinergic stimulation	<ul style="list-style-type: none"> <li>Manifests as increased sweating, excessive salivation, increased bronchial secretions, priapism and bradycardia</li> <li>Appear within 1–2 hours and can last for up to 6–13 hours</li> </ul>
Profuse sweating	<ul style="list-style-type: none"> <li>Sweat literally flows all over the body; it is often called as skin diarrhea</li> <li>It can persist for 3–17 hours</li> </ul>
Salivation	<ul style="list-style-type: none"> <li>Stimulation of the bronchial mucosa will result in thick ropy salivation</li> <li>It is often difficult to expectorate in children</li> <li>Can occur soon after sting and it can persist for 2–4 hours</li> <li>Excessive salivation and bronchial secretion are major contributing factors for respiratory failure</li> </ul>
Priapism	<ul style="list-style-type: none"> <li>Priapism seen in almost all male children of all age group and 20% of adult's patients envenomed by scorpions of Buthidae family except Hemiscorpion</li> <li>Priapism is the diagnostic of venomous scorpion sting</li> <li>Its absence or disappearance did not correlate the outcome</li> <li>It can persist for 5–16 hours</li> </ul>

Vomiting, profuse sweating, salivation, priapism are diagnostic of cardiac premonitory signs of scorpion sting envenomation and suggestive of circulating unbound venom in the body, can be accessible to scorpion antivenom therapy

pulmonary edema with central cyanosis, intractable cough with continuous expectoration of blood-stained froth from mouth and nostril may occur.

## Other Reported Complications

### Neurological Complications

The venom of the bark scorpion (*Centruroides exilicauda*), found in parts of the US is highly neurotoxic. *Mesobuthus tamulus* may cause focal neurological presentation including hemiparesis, hemorrhagic or thrombotic stroke. Hypoxia caused by pulmonary edema and cardiovascular failure also contributes to neurologic complications. There is a poor outcome in patients presenting with coma, convulsions, hyperthermia or brain edema.

### Acute Pancreatitis

In India, acute pancreatitis due to scorpion sting envenomation in children is a rare clinical presentation. There is 80% incidence of acute pancreatitis due to envenoming by *Tityus serrulatus* in Trinidad. In Israel, envenomation by *Leiurus quinquestriatus* in children instigates agitation, abdominal pain, discomfort and vomiting, with raised plasma immunoreactive cationic trypsin.

### Cause of Mortality

Due to lethal ventricular arrhythmias, death may occur within 30 minutes of sting. Delayed hospitalization due to poor transport, seeking traditional remedies, and lack of experience in the treatment of scorpion bites contribute to the high fatality due to scorpion sting. Excessive fluid administration may cause or worsen myocardial dysfunction. The oxygen demand of the myocardium and the necrotizing effects of circulating catecholamines are relatively increased by steroids. The oxygen requirement and increased myocardial contraction is further enhanced by digitalis.

## INVESTIGATIONS

Cardiac markers are most useful in the detection of minor myocardial injury when individuals have nondiagnostic ECG tracings. Cardiac markers used in clinical practice are cardiac enzymes—creatinine kinase, cardiac troponin I, cardiac troponin T and myoglobin. Echocardiography, ECG and chest X-ray are useful tools for the assessment of severity of myocardial involvement (Table 6).

## MANAGEMENT

The case fatality due to scorpion sting was up to 29% during the latter half of the previous century despite various treatments comprising of lytic cocktail, propranolol, decongestive agents, and insulin-glucose drip. In recent years, there is negligible fatality due to severe scorpion envenomation because of the advent of scorpion antivenom (SAV), intensive care facilities and vasodilators.

### Pain Relief and Fluid Management

In the case of severe pain, nonsteroidal anti-inflammatory drug is used to provide long-time relief. Other measures used to relieve pain are ice packs and xylocaine (local anesthetic). To settle a restless child after a sting, midazolam or diazepam is used.

Profuse sweating and vomiting cause loss of fluid, this is very often overlooked and can cause complications in the clinical course. Efforts should be taken to correct the fluid deficit and maintain the fluid balance. Hence, oral fluids should be given whenever possible. Children showing symptoms of altered sensorium and tachypnea require parenteral fluids. Care by pediatric intensive care unit and central venous pressure monitoring become vital as fluid requirement needs to be balanced with care in children with pulmonary edema.

**Table 5** Systemic manifestations of scorpion sting—due to adrenergic stimulation

Symptoms and signs	Clinical manifestation and implication
Adrenergic stimulation	Leads to tachycardia, hypertension and peripheral circulatory failure and further to myocardial injury and pulmonary edema
Cold extremities	<ul style="list-style-type: none"> <li>Cold extremities are usually due to severe vasoconstriction in response to the circulating catecholamine and can persist for 12–26 hours</li> <li>Skin over palm and dorsum look like a <i>washer man's hand</i></li> <li>Often associated with severe cardiovascular manifestations</li> <li>Recovery is associated by improvement in skin temperature, which serves as an <i>ideal clinical monitor</i> for the lay person at a primary care setting</li> </ul>
Mydriasis	<ul style="list-style-type: none"> <li>Dilated nonreacting or poorly reacting pupils often seen in the early phase of autonomic storm associated with hypertension</li> <li>Effects are due to stimulation of <math>\alpha</math>-receptor of dilator pupillary muscles by excessive circulating catecholamine</li> </ul>
Tachycardia	<ul style="list-style-type: none"> <li>Usually appears within 4 hours of the sting and can persist for up to 24–72 hours</li> <li>It is due to direct <math>\beta</math>-adrenergic stimulation of the heart</li> <li>In most cases, the tachycardia may resolve without any further progression to complications, but when it increased in severity and associated S3 gallop, and ice-cold extremities appear; it is an indicator of myocardial injury</li> <li>Impaired left ventricular filling, reduction in cardiac output due to marked tachycardia particularly in children results in delirium and convulsion due to anoxia to the brain</li> </ul>
Hypertension	<ul style="list-style-type: none"> <li>Due to <math>\alpha</math>-receptor stimulation induced vasoconstriction and <math>\beta</math>-receptor-mediated increase in cardiac contractility</li> <li>Appears within 2 hours of sting and can last for 4–8 hours</li> <li>Hypertensive stress on the myocardium, direct myocyte toxicity and catecholamine-induced injury contribute to rhythm disturbances and left ventricular failure</li> </ul>
Hypotension	<ul style="list-style-type: none"> <li><i>Transient hypotension</i>: As a result of vomiting, profuse sweating, salivation and cardiac arrhythmias</li> <li><i>Delayed hypotension</i>: As a result of the reduction in systemic vascular resistance, hypokinetic phase, hypotensive shock indicative of a reduced left ventricular contractility</li> <li><i>After 24–48 hours of admission</i>: Asymptomatic compensated shock with bradycardia but good volume pulse with warm extremities associated with prolonged corrected QT interval is usually due to depletion of catecholamines from nerve terminals</li> <li>Venom inhibits kinase II enzyme and resulting in elevation of bradykinin, a neuromuscular agent involved in the development of pulmonary edema and hypotension</li> </ul>

**Table 6** Echocardiography, electrocardiogram and chest X-ray findings in scorpion sting envenomation

Modality	Finding and clinical significance
Echocardiographic study	<ul style="list-style-type: none"> <li>Abnormal echocardiography will appear within 12–15 hours of sting</li> <li>Findings of poor global hypokinesia with reduced ejection fraction, decreased left ventricular performance and index, trivial mitral regurgitation, abnormal diastolic filling pressure</li> <li>Systolic and diastolic frames usually show no change in diameter and flattening of the interventricular septum with no systolic thickening</li> <li>There is a good correlation between clinical improvement and return of the left ventricular function toward normal in the Indian red scorpion sting envenomation</li> <li>Serial echocardiography study is useful to follow changes in myocardial function and possibility of development of cardiomyopathy</li> <li>Return to normal within 5 days to 4 weeks</li> </ul>
Electrocardiogram	<ul style="list-style-type: none"> <li>All patients with systemic involvement usually show abnormal ECG</li> <li>Abnormal ECG suggestive of myocardial injury without clinical feature of myocardial dysfunction not uncommon</li> <li>The most frequent ECG abnormalities are RST segment and T waves</li> <li><i>In acute myocardial injury</i>: Arrowhead tented T wave look like <i>Ashoka tree</i> appearance</li> <li><i>Recovery of myocardial injury</i>: Tent-shaped look like <i>Christmas's tree</i> appearance</li> <li>Usually described patterns of ECG abnormalities are early myocardial infarction like pattern, atrial arrhythmias, non-sustained ventricular tachycardia and varies conduction defect</li> <li>Indicator of serious myocardial injury: PQRS or T wave alternans</li> <li><i>Time to normalization</i>: Prolonged corrected QT and conduction defect normalized within one week, T wave inversion can persist for up to few weeks</li> <li><i>Poor prognosis indicators</i>: Low voltage ECG complex, wide QRS complex, tachycardia, hemiblock and marked ST segment depression</li> </ul>
Chest X-ray	<p>Features suggestive of cardiogenic pulmonary edema are:</p> <ul style="list-style-type: none"> <li>Unilateral distribution or bat wing appearance of lung edema usually due to left ventricular dysfunction and localized elevation of pulmonary vascular permeability</li> <li>The patchy and peripheral distribution of lung edema with air bronchograms are usually due to increased vascular permeability</li> </ul>

## Vasodilators

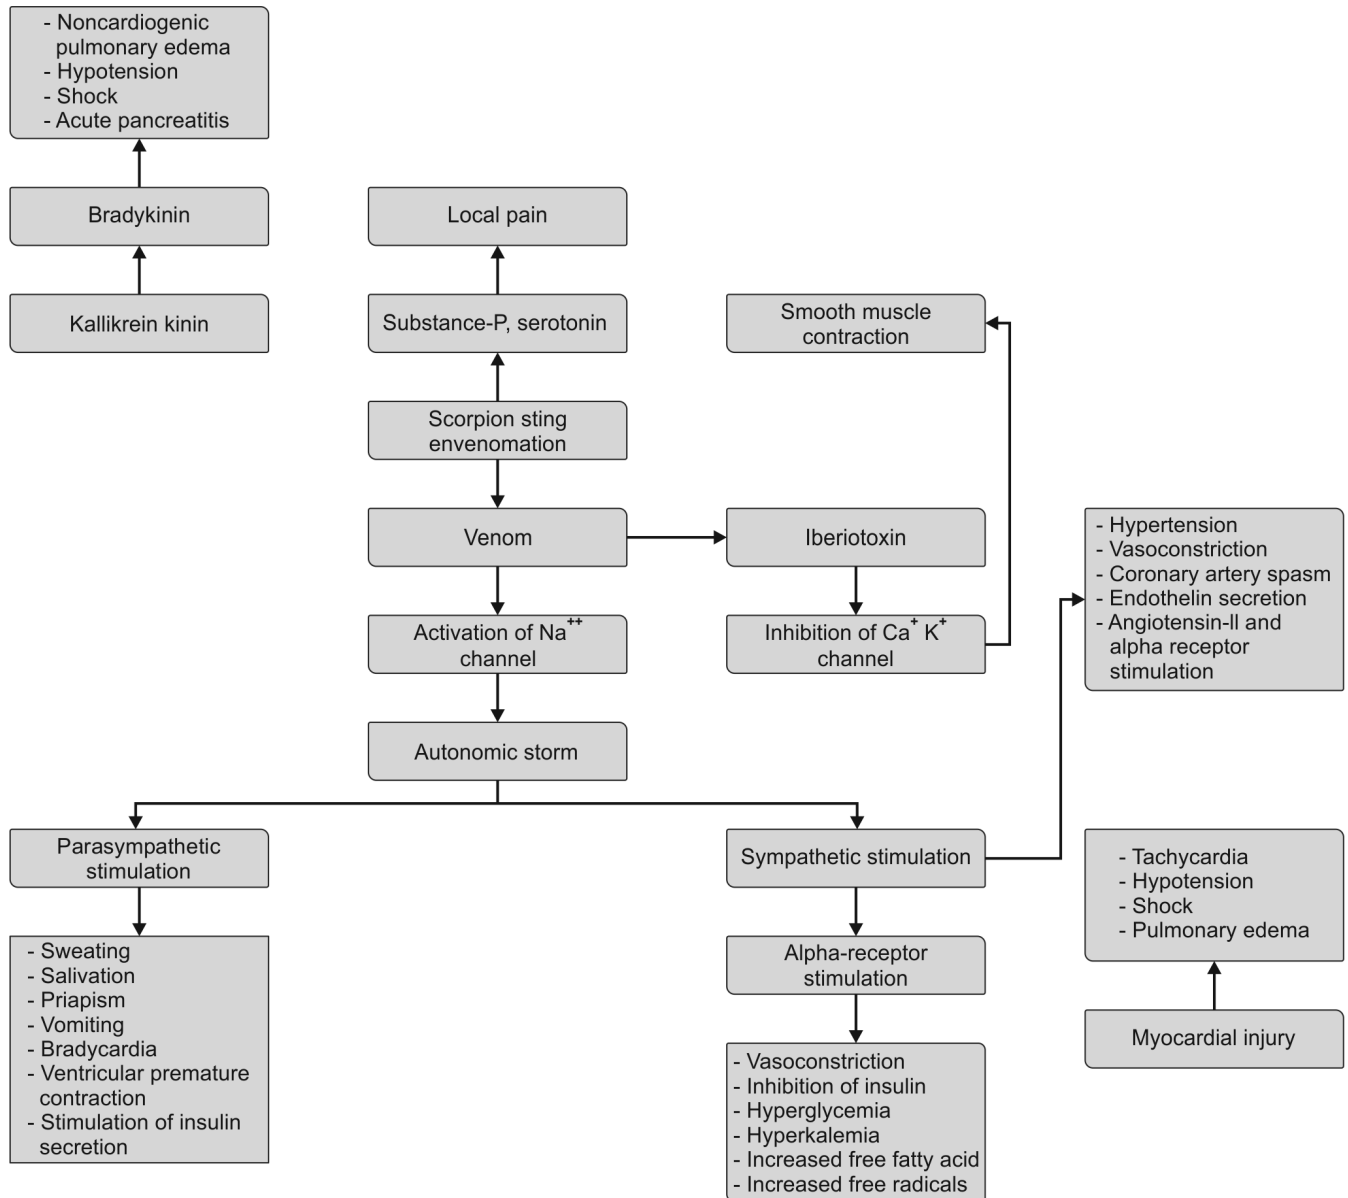

Five drugs—prazosin, chlorpromazine, dobutamine, nitroglycerine and sodium nitroprusside have been used individually or in combination in the pharmacologic support of patients with scorpion envenomation and cardiovascular manifestations.

## Prazosin

Since  $\alpha$ -receptor stimulation plays a chief role in the clinical manifestations in scorpion sting envenomation, prazosin that is a competitive postsynaptic  $\alpha_1$ -adrenoceptor is the first line of management. Prazosin subdues sympathetic effects and activates

Flow chart 2 Mechanism of scorpion sting envenomation

venom-inhibited potassium channels. It decreases the preload, afterload and blood pressure without mounting the heart rate. Vasoconstriction induced by endothelins is countered by prazosin through accumulation of cyclic guanosine monophosphate (cGMP). Prazosin is useful in the reversal of hormonal and metabolic effects of  $\alpha$ -receptors stimulation. Thus, prazosin is both a *pharmacologic and cellular antidote* to the actions of scorpion venom, with the added advantage of being cardioprotective.

It is available as an oral preparation in the form of 1 mg tablets. Owing to its photosensitivity it has to be stored in airtight containers away from light. Sustained-release tablets are not suitable in this condition. As an immediate measure, *the suggested dose of 30  $\mu\text{g/kg/dose}$*  is given to all patients showing evidence of autonomic storm. It is not to be given as prophylaxis in children when the only symptom is pain. In the case of vomiting, it can

be administered through nasogastric tube. After giving prazosin, mother should be advised not to lift the child to prevent the effects of *first dose phenomenon* due to prazosin. Oral hydration and milk feed must be encouraged. If needed, intravenous maintenance fluids should be given to correct dehydration due to excessive sweating and vomiting.

Prazosin can be given irrespective of blood pressure values provided there is no hypovolemia. However, with availability of SAV and comparative studies of dobutamine, prazosin should be avoided in those patients with borderline or hypotensive blood pressure. Close monitoring of vitals including blood pressure; pulse rate and respiration must be monitored at least every 30 minutes for 3 hours, every hour for next 6 hours and thereafter every 4 hours till improvement. Repeat dose prazosin should be considered at same dose after the 3 hours of the first dose based on clinical response

and can be given till improvement of symptoms like extremities are warm, dry and peripheral veins are easily visible. In general, no more than four doses have been required in the majority of children with scorpion sting envenomation. A major adverse effect in the use of prazosin is the occurrence of the *first dose* phenomenon, while the mechanism of action is not clear, it is seen to occur more commonly in patients who are salt and volume depleted.

### Management of Pulmonary Edema

Pulmonary edema in these children is mainly due to myocardial dysfunction. Though serious in itself, it does not necessarily mean a poor prognosis. Despite diagnostic and therapeutic advances, the management of myocardial dysfunction in the scorpion sting envenomation in children remains supportive. In children with pulmonary edema with or without hypertension, management should be directed toward relieving afterload without compromising preload. The use of diuretics to minimize or reduce fluid overload seems a reasonable measure but only when renal water excretion is impaired. Otherwise, the best way to prevent fluid overload is to maintain an adequate cardiac output. Thus dobutamine support (5–15 µg/kg/min) with vasodilatation through sodium nitroprusside (0.3–5 µg/kg/min) or nitroglycerine (0.1–1 µg/kg/min) infusion is preferred in this situation. Prazosin is to be given 1 hour before termination of sodium nitroprusside drip. If sodium nitroprusside is not available, one can use isosorbide dinitrate, 10 mg every 10 minutes sublingually as an emergency measure. Morphine, a standard therapy in pulmonary edema, should be avoided in scorpion sting, since narcotics worsen dysrhythmias in these children.

Occasionally, children with scorpion sting present with multi-organ failure. A systemic inflammatory response is presumably the cause; however, our knowledge on the pathogenesis of such a state is still incomplete. Presence of respiratory failure with or without CNS disturbances in the presence of hypertension or complicating those children with pulmonary edema should be aggressively treated with early ventilation, afterload reduction, careful sedation and acid-base correction.

### Scorpion Antivenom

Scorpion antivenom should be administered as soon as possible and through intravenous route over 30 min after reconstitution of three vials in 100 mL normal saline. In general, *Hottentotta tamulus* (*Mesobuthus tumulus*) sting envenomation causes transient parasympathetic and prolonged sympathetic stimulation. Presence of signs and symptoms of parasympathetic stimulation suggests that unbound scorpion venom is circulating in the circulation and available for neutralization by SAV. Hence, SAV can subsequently prevent the sympathetic overstimulation and its consequences like autonomic storm. Study from Mexico found that since the advent of extensive use of SAV associated with a dramatic reduction of fatality during the last decade.

Debate of efficacy of SAV as a specific antidote for scorpion sting envenomation has been resolved by recent randomized controlled trials involving the children and adults with scorpion sting proved that beneficial effects of early administration of SAV. Intravenous administration of SAV resolved the neurological manifestations within 4 hours along with a reduction of concomitant requirement of sedation with midazolam and decreased the unbound venom in the circulation. Nowadays, SAV is becoming available almost in all tropical and subtropical countries where scorpion sting envenomation is the one of the major issues. Study from Razi Institute, Iran found that a polyvalent SAV inhibits the gelatinase enzyme activity of *Hemiscorpius lepturus* species sting envenomation and is associated with a

better prognosis. In India, since 2002, SAV have been available for clinical management of scorpion sting envenomation from Haffkine Biopharma, Mumbai. The current recommended dose of SAV is single 30 mL (3 vials) dose of Haffkine Biopharma monovalent SAV diluted in 100 mL of normal saline infused intravenously over 30 min irrespective of age and weight of the patients.

### Unhelpful Treatments

Standard therapy was not clearly defined in earlier days; many therapies were in vogue without experimental justification; these should be avoided.

- **Lytic cocktail** (*Pethidine* + *Promethazine* + *Chlorpromazine*) The  $\alpha$ -blocking effect of chlorpromazine might be beneficial, but pethidine may convert sublethal dose of scorpion venom into a lethal one, and they also interfere with protective respiratory reflexes.
- **Morphine** Worsens dysrhythmias in children with scorpion sting envenomation.
- **Steroids** Moreover, steroids might enhance the necrotizing effects of excessive catecholamines on myocardium. It should not be used in the scorpion sting management.
- **Atropine** Complete abolition of parasympathetic effects may permit the domination of the overstimulated sympathetic system. Atropine potentiates tachycardia and sustains hypertension.
- **Nifedipine** Reflex tachycardia and negative inotropic effects argue against its use; despite its antihypertensive and vasodilator effect, 35% of scorpion victims developed myocardial failure and 14% acute pulmonary edema.
- **Angiotensin-converting-enzyme inhibitors** Captopril aggravates hyperkalemia and inhibits the breakdown of bradykinin, which is implicated in experimental pulmonary edema due to scorpion sting.

### PREVENTIVE MEASURES

The following preventive measures can be considered: Clear debris and trash from the areas one inhabits. Inspect boots, clothing and bedding for scorpion. Never explore into places one cannot see. Spraying 10% DDT + 0.2% pyrethrin + 2% chlorine in oil base or fuel oil + kerosene + creosote as spray in roof complexes and building foundations.

#### IN A NUTSHELL

1. Scorpion venom is a potent sympathetic stimulator.
2. Cardiac manifestations are common in Indian red scorpion envenomation.
3. Alpha-receptors stimulation plays a significant role in the evolution of myocardial dysfunction and acute pulmonary edema in victims of scorpion sting.
4. Prazosin— $\alpha$ -adrenoceptor antagonist—is cellular and pharmacological antidote to scorpion sting envenomation.
5. Time lapse between the sting and administration of prazosin and/or SAV for autonomic storm determines the outcome.
6. Scorpion antivenom is gaining widespread recognition in the management of scorpion sting envenomation.

# Section 10 CHILDHOOD INJURIES

**Section Editor** Rakesh Lodha

## Chapter 10.1

### Trauma: Stabilization, Triage and Transport

*Shruti Kant, Manu Madhok*

Injuries are an important cause of death and morbidity in the pediatric population. Physicians caring for children must be prepared to provide initial triage and treatment for injured children. Trauma in the pediatric population is a unique problem as children have several distinguishing anatomic, physiologic and developmental characteristics. These differences and their environment make them susceptible to injury patterns that differ from adults and can provide a diagnostic challenge. One must take these differences into consideration in the medical approach to an injured child. Having an understanding of the epidemiology, etiology, anatomic and physiologic considerations of pediatric trauma can help the physician develop a systematic approach in identifying and treating injuries in children. This chapter aims at preparing physicians for initial assessment, stabilization and transport of the injured child.

#### EPIDEMIOLOGY

Childhood injury accounts for a significant burden of disease worldwide. The World Health Organization (WHO) along with The United Nations Children's Fund estimates that across the world, over 900,000 children less than 18 years of age die annually as a result of injuries. Even in developing countries, where infectious diseases predominate, injuries are a leading cause of mortality and morbidity. While the burden of childhood injuries is not clearly known in India and other developing countries, several authors and agencies have sought to add to the epidemiological data and trends. According to the National Crime Records Bureau report of 2012, there were 22,514 accidental deaths among children less than 14 years in India.

While injuries are not gender specific, in general males tend to outnumber females with a ratio of 2:1. This is true worldwide and may be due to increased freedom afforded to males in developing countries as well as an increased tendency for risk-taking behavior among boys.

According to most authors 50-60% of injuries occur in the home setting with falls as the number one cause. Other common locations are in the street or playground. While falls are the most common cause of injury, road traffic accidents (RTAs) are the most common cause of death due to injury in children. Children most often present with blunt force trauma, although on occasion they may have penetrating trauma such as gunshot wounds or stab wounds. Head injuries and orthopedic injuries are the most common types of injuries sustained by children requiring admission to the hospital (**Box 1**).

#### ETIOLOGY

The etiology of pediatric trauma is outlined in **Box 2**. Risk factors for injury are listed in **Table 1**.

#### MODES OF INJURY

Falls are the most common cause of injuries in children. In the home setting, they can fall from stairs, ladders, furniture such as beds and sofas, parapets and rooftops. One study out of Rajasthan found that children frequently fell from the first story due to the low height of the parapets. Unlike RTAs, children with falls are less likely to have severe injuries requiring hospital admission. Most are treated in the outpatient department and discharged home.

Road traffic accidents are a leading cause of injuries and death in children. Unlike adults, the pediatric population is more likely to suffer pedestrian versus motor vehicle collisions. Victims of RTAs are more likely to suffer severe injuries, require emergency surgery, have prolonged hospital stays and have long-term disability.

Burns in children are most often scalds due to hot liquids. Other causes of burns include flame and electricity. Both genders are equally affected with a male:female ratio of approximately 1:1. A significant number of children with burns require hospitalization for treatment of their wounds.

#### BOX 1 Pediatric trauma epidemiology facts

- Annually more than 900,000 deaths occur in children under 18 years across the globe due to injuries
- Road traffic accidents are the leading cause of death due to injury
- Drowning is the third leading cause of death due to injury
- Falls are the most common cause of injury
- 50–60% injuries occur in the home setting.

#### BOX 2 Common modes of injury

- Falls
- Road traffic accidents
- Burns (flame, hot water, hot oil, etc.)
- Accidental poisoning
- Drowning.

**Table 1** Risk factors for injury

Patient factors	Parent factors	Environmental factors
Level of development	Lack of supervision	Overcrowding
Underlying medical problem	Lack of education/awareness	Poor road conditions
Lack of situational awareness	Not enforcing safety devices	Poor engineering
Not using protective equipment	Improper storage of chemicals	Low socioeconomic status
Use of intoxicating substance	Distracted driving	Natural disasters
Risk taking behavior		

Accidental poisoning by ingestion of medications or cleaning agents is another frequent cause of childhood injury. The age group most commonly affected is 1–4 years old with a male preponderance.

Drowning is the third leading cause of unintentional injury death in the world. According to the WHO low- and middle-income countries, such as India, account for 95% of drowning deaths. Children less than 5 years of age have the highest mortality rate due to drowning. Males are at a higher risk of drowning than females.

### Patient Risk Factors

Host characteristics associated with increased risk of injury include the developmental stage of the child, risky behavior, underlying medical problems, lack of awareness of surroundings and use of intoxicating substances.

### Parent Risk Factors

Parent characteristics associated with an increased risk of injury for children include lack of supervision, not enforcing use of protective equipment, such as helmets and seatbelts, lack of education/awareness of safety hazards and improper storage of household medications/cleaning agents.

### Environmental Risk Factors

These include factors such as low socioeconomic status, overcrowding, use of intoxicating substances and natural disasters such as flooding or earthquakes.

## PATHOGENESIS/PATHOPHYSIOLOGY

Several physiologic and anatomic characteristics are unique to children and should be taken into consideration when evaluating and managing a child with injuries (**Table 2**).

### Size and Shape

Children have a much smaller size and body mass. This results in transmission of a much greater amount of energy per unit body mass. Children have much less fat and subcutaneous tissue, which bring the internal organs in closer proximity to the surface. Therefore, the greater energy transmitted through the body can cause a higher incidence of multiple organ injury. Children have proportionately larger heads, which put them at higher risk for blunt head trauma. With the smaller body mass and larger head, children have a larger body surface area to volume ratio. The greater body surface area allows for added temperature loss putting this age group at increased risk for hypothermia.

**Table 2** Anatomic and pathologic considerations

<i>Size and shape</i>
<ul style="list-style-type: none"> <li>• Small size (more force transmitted)</li> <li>• Large head (increased trauma risk)</li> <li>• Less fat and subcutaneous tissue (organs closer to surface)</li> <li>• Larger body surface area (hypothermia risk)</li> </ul>
<i>Skeletal immaturity</i>
<i>Airway</i>
<ul style="list-style-type: none"> <li>• Tongue large compared to mouth</li> <li>• Larynx more anterior</li> <li>• Large occiput (passive neck flexion)</li> <li>• Short trachea</li> </ul>
<i>Circulation: Significant physiologic reserve</i>

### Skeletal Immaturity

Incomplete calcification and open growth plates make the skeleton in this age group pliable. The skeleton is able to transmit a greater amount of force internally to the organs without sustaining any bony injury or fracture. Thus, it is not uncommon to see injuries such as pulmonary contusion or cerebral contusion without rib fractures or skull fracture. The corollary to this is that fractures of certain bones, such as ribs or skull, implies transfer of a massive amount of energy and as such should alert the physician to the possibility of significant internal injuries such as traumatic brain injury, pulmonary contusion, pneumothorax, mediastinal injury, etc.

### Airway

There are several anatomic considerations which affect the management of the pediatric airway:

1. The tongue and tonsils in a child are relatively large compared to the size of the oral cavity, making visualization of the larynx and vocal cords more difficult.
2. The larynx is more anterior and cephalad, also making visualization more difficult.
3. The epiglottis can be floppy again making visualization of the cords difficult.
4. The child's large occiput causes passive flexion of the airway; particularly the posterior pharyngeal tissue has a tendency to buckle resulting in airway obstruction. This obstruction can be avoided by placing a 2 cm thick layer of padding beneath the shoulders and torso. This helps to maintain a neutral head position and opens up the airway.
5. The infant trachea is much shorter which makes it easy to intubate the right mainstem bronchus or to cause dislodgement of the endotracheal tube. In either case, this can lead to inadequate oxygenation and ventilation. Right mainstem intubation can also result in barotrauma from hyperinflation of the right lung.

### Circulation

Children generally have great physiologic reserve and can maintain a state of compensated shock with a normal blood pressure even in the face of significant hypovolemia from blood loss. It may take up to a 30% loss of blood volume before a child will manifest a drop in blood pressure. It is important for the physician to recognize the subtle signs of shock in an injured child of which tachycardia and delayed capillary refill time are the earliest signs.

## CLINICAL FEATURES

Pediatric trauma victims can have a range of clinical presentations. They may have minor injuries such as simple contusions or lacerations or present with multiple trauma. It is up to the physician to systematically determine the extent of the child's injuries. Certain clinical features can aid the medical provider in making these determinations.

### Airway

Stridor may represent partial airway obstruction due to an object or swelling from trauma. Paradoxical chest/abdominal movement may signal complete airway obstruction.

### Breathing

Tachypnea is a frequent finding in children with injuries. Tachypnea alone may be due to anxiety, blunt trauma to the chest, drowning and ingestion of a toxic substance. Decreased breath sounds can suggest pulmonary contusion, pneumothorax or hemothorax. Paradoxical chest movement can indicate flail chest.

Bradypnea can indicate significant head injury and may signal a need to secure the airway by intubating.

Pulse oximetry can also aid in assessing for respiratory compromise.

### Circulation

Children usually have a large physiologic reserve. Tachycardia is one of the earliest clinical signs of hypovolemic shock. Other subtle signs include pale or mottled skin, cool or clammy extremity skin compared with central skin, weak/thready peripheral pulses. Drop in blood pressure and altered level of consciousness are late signs of hypovolemic shock. Average systolic blood pressure in children is (90 mm Hg plus  $2 \times$  age in years). The lower limit of systolic blood pressure is (70 mm Hg plus  $2 \times$  age in years). Physicians should pay close attention to the subtle changes in circulation and institute early resuscitation.

### Abdomen

Abdominal injury can present with bruising, abdominal tenderness, guarding, rigidity, abdominal distension or blood in the rectum. Seatbelt sign across the lower abdomen can be a harbinger of hollow viscus injury and/or a Chance fracture of the lumbar vertebrae. Flank tenderness can be suggestive of renal or adrenal injury. Hematuria and blood at the urethral meatus is indicative of genitourinary injuries. Pelvic instability suggests transmission of significant forces and should alert the physician to the possibility of genitourinary injuries and other intra-abdominal injuries.

### Neurologic

Altered level of consciousness can be indicative of direct head injury, poor cerebral perfusion due to uncompensated hypovolemic shock, decreased oxygenation of the brain or hypoglycemia. Patients may present with paresis, paralysis or decreased sensation suggesting spinal cord injury.

### Head, Eyes, Ear, Nose and Throat

An irregular pupil or conjunctival hemorrhage suggests eye trauma. Leakage of cerebrospinal fluid or blood from the nares or ear canals can be suggestive of basilar skull fracture. Additional findings of skull fracture can include Battle's sign (ecchymosis behind the ears), raccoon eyes (ecchymosis around the eyes). There may be maxillofacial instability indicating fracture of the facial bones.

### Musculoskeletal

Fractures are suggested by swelling, tenderness, crepitus and/or deformity. Similarly, sprains and strains can be suggested by joint instability. A tight swollen extremity with decreased sensation, severe pain, decreased or absent pulses suggests compartment syndrome.

### DIFFERENTIAL DIAGNOSIS

When assessing an injured child, it is important that the physician avoids premature closure and thus misses possible underlying problems whether they are occult injuries or other medical problems. The differential can therefore be broad. For example, a patient presenting with altered level of consciousness with a history of a fall may have sustained intracranial injury. But it is important to consider other possible causes of altered mental status—Did the child ingest a toxin? Did the child have a seizure? Was a syncopal event due to cardiac arrhythmia or hypoglycemia the cause of the fall? Did the child sustain any injuries other than the obvious head injury?

One can help ascertain the extent of a patient's injuries and possible medical problems by eliciting a thorough history, performing a thorough exam and using diagnostic studies and imaging as indicated and after initial stabilization of the patient.

### TRIAGE

Trauma patients can have injuries that vary from a simple splinter to the victim of a RTA with multiple trauma causing significant hemodynamic or respiratory symptoms. It is the responsibility of the physician to determine the extent of the child's injuries. This can be a rather difficult process but can be achieved through triage.

Triage is a very difficult process. Triage involves the initial sorting by which a physician can quickly assess the extent and severity of a patient's injuries and determine the treatment priorities for stabilization.

Initial assessment of a trauma victim can be done in just a few seconds by assessing the airway, breathing, circulation and debilitation (ABCD). For example, an appropriate response to the question of name and recent events by the patient tells the physician that the airway, breathing and mentation are not significantly compromised. Difficulty in responding to these questions indicates compromise of A, B, C and/or D. However, this simple assessment may be difficult to make in the infant or young child, who may be too young or too anxious to respond appropriately.

Other considerations during the initial assessment are whether the patient sustained localized trauma such as an isolated extremity injury or if there is multiple trauma to different sites. This is not an easy determination to make as certain injuries can be occult, the patient may not be cooperative with attempts to examine them due to age or intoxication. Thus, this is a dynamic process and the physician must keep an open mind and perform a thorough exam. When in doubt, it is best to assume multiple trauma until proven otherwise.

### Mass Casualty Events

A mass casualty event is defined when the number of patients exceeds the capacity of the resources (personnel and facility) available. In mass casualty situations, the goal of triage is to provide care to those patients who will most benefit from the limited resources. The priority is to maximize the number of victims who survive. This means that the medical provider may need to withhold care from some patients who, under different circumstances, would have received medical care.

As you can imagine, this is a formidable and stressful process for medical providers who have to choose which patients should receive care and which ones should not. Often in these situations, the tendency is to overtriage children, thus assigning resources to children who neither need nor benefit from them. So the physician must be wary of this pitfall.

There are several mass casualty incident (MCI) triage systems available. The Simple Triage and Rapid Treatment (START) system is one of the most popular triage tools used by many countries. Other triage tools include SALT (Sort, Assess, Lifesaving intervention, Treatment/Transport), Triage Sieve, CareFlight Triage, etc. JumpSTART is a modification of the START tool, which is more suitable for children and parallels the START tool. It is currently the most widely used MCI triage tool suitable for children. Sacco triage system is a newer tool developed for children.

### STABILIZATION

The goal of management of the injured child is to minimize secondary injury as a result of the primary injury. The Advanced

**Figure 1** Layout of a trauma emergency care room

Trauma Life Support (ATLS) recommends a systematic and team approach. The approach to management involves systematically assessing the ABC's and providing interventions as indicated by clinical presentation. After each intervention it is important that the physician assess the patient's response. The clinician should not move to the next step until the first problem has been effectively dealt with. The primary survey involves evaluation of airway, breathing, circulation, disability and exposure (**Fig. 1**).

### Airway

The first step is assessment of airway patency. A crying or verbal child indicates a patent airway. If the patient has signs of airway obstruction as described in the clinical features section, it must be addressed immediately. There are several interventions a physician can perform to establish an open airway. Ensure the patient is placed with head in the neutral position (the child's midface should be parallel to the surface they are laying on). Performing the jaw thrust maneuver can further open the airway. Consider possibility of cervical spine injury and avoid excessive motion of the neck. Ideally the cervical spine should be immobilized with a semi-rigid collar or with sandbags. If the child still has signs of airway obstruction, the physician will need to establish a definitive airway. Physicians should be alert to the fact that in the case of burn victims a definitive airway should be established at the earliest sign of developing obstruction.

### Breathing

The physician should note tracheal position, assess for jugular distension, equal chest rise and breath sounds. If there is a suspicion of tension pneumothorax or massive hemothorax, a chest tube should be placed, after confirming the same. In the case of significant respiratory compromise with poor oxygenation and/or ventilation due to flail chest or pulmonary contusion, endotracheal intubation should be undertaken as indicated.

### Circulation

Important clinical aids to assessing the circulatory status include heart rate, pulses in all extremities, capillary refill time, level of consciousness and skin color. If patient has signs of hypovolemic shock, the physician should immediately institute fluid resuscitative measures with isotonic fluid and blood transfusion as needed. Hemorrhage is the most common cause of shock in trauma victims. It is imperative that the physician identifies the source of bleeding and achieves hemostasis. External bleeding is easily identified and best controlled by direct pressure. In cases of massive external hemorrhage not controlled by direct pressure, a temporary tourniquet may be applied. Identification of internal bleeding can be more of a challenge. There are several areas of the body where a child can have significant blood loss before overt clinical signs are visible such as abdomen/pelvis, retroperitoneum and thigh. Management of internal hemorrhage may require surgical intervention.

## Neurologic Evaluation

A quick neurologic assessment can be obtained by using the Glasgow Coma Scale or the alert, voice, pain, unresponsiveness (AVPU) method to assess mental status. Depressed level of consciousness can be due to direct trauma, decreased oxygenation and/or perfusion and should prompt reassessment of the patients ABC's. The goal of management in traumatic brain injury is prevention of secondary injury to the brain by maintaining appropriate perfusion and oxygenation of the brain as well as a euglycemic state.

## Exposure

The patient should be completely undressed for several reasons: This facilitates a complete evaluation; prevents hypothermia—if the clothes are wet, they can cause cooling and aids in removal of toxic exposures if the clothes are saturated. Once patient evaluation is complete, they should be covered with blankets to prevent hypothermia. After the primary survey and stabilization is achieved, a complete head to toe exam should be done to identify all injuries. This is also the time when laboratory and imaging studies can be obtained as clinically indicated to aid in diagnosis and further management (**Table 3**).

## TRANSPORT

On occasion it may be necessary to transport an injured patient for more definitive care. A patient should be transferred if their medical or surgical needs exceed or may exceed the capabilities of the current facility. Transport should occur in a timely manner once the patient has been stabilized to the extent possible given resources and physician capability. Transfer should not be delayed for diagnostic testing (laboratory or imaging) which will not change the need for transfer. For example, if the patient is stable but needs to be observed for a splenic laceration and possible ongoing hemorrhage that may need surgical intervention, this observation should be done at a facility where there is a surgical team and operating theater immediately available. During transport there should be ongoing monitoring of vital signs and support of the cardiopulmonary system.

## OUTCOMES/PROGNOSTIC FACTORS

Globally, approximately 950,000 deaths occur each year in children under 18 years. Nearly 95% of these deaths occur in low- and middle-income countries. In India, injury is the second leading cause of death in the 5-14 years age group and the fourth leading cause of death for children less than 15 years. Due to the lack of a national trauma registry, limited data is available on trauma outcomes and prognostic factors in India. Several authors have conducted studies to determine the utility of trauma prediction scores such as the Revised Trauma Score (RTS), Injury Severity Score (ISS) and the Trauma and Injury Severity Score system,

which combines the RTS, ISS and age to determine the probability of survival.

It has been reported that the trauma mortality rate in developing countries is significantly higher than developed countries. One of the chief causes for this is the lack of prehospital care, which causes a time lag to definitive care and misses the *golden hour* for instituting lifesaving therapies.

The compelling need for an organized trauma system has been well established in the literature. Considerable efforts should be made to develop a national trauma registry, organized prehospital care, a medical transportation network and regional trauma centers.

## PREVENTION

Primary injury prevention should be a goal for all physicians who provide care to children. Just as we have made strides in preventing infectious diseases through immunizations and clean healthful practices so we should focus our efforts on preventing childhood injury. We need to understand the scope of the problem, risk factors associated and some of the barriers to prevention efforts, which are unique to India and similar developing countries. There is a paucity of epidemiological information related to injuries in India. Earnest efforts should be made to establish a reliable surveillance system to accurately define the burden of disease.

Injury prevention requires a multipronged approach and should include collaborative efforts between various sectors such as media (education), engineering (safety devices, safer roads), policy makers (legislature) and law enforcement. These efforts should be continued on national, state, regional and community levels.

### IN A NUTSHELL

1. Most injuries occur in the home setting with falls as the number one cause. Other common locations are in the street or playground.
2. Road traffic accidents are the most common cause of death due to injury in children.
3. Burns in children are most often scalds due to hot liquids. Other causes of burns include flame and electricity.
4. Accidental poisoning by ingestion of medications or cleaning agents is another frequent cause of childhood injury. The age group most commonly affected is the 1–4 years old with a male preponderance.
5. Drowning is the third leading cause of unintentional injury death in the world. Low- and middle-income countries accounts for 95% of drowning deaths. Children less than 5 years have the highest mortality rate due to drowning.
6. Triage involves the initial sorting by which a physician can quickly assess the extent and severity of a patient's injuries and determine the treatment priorities for stabilization. It is the responsibility of the physician to determine the extent of the child's injuries.
7. The goal of management of the injured child is to minimize secondary injury as a result of the primary injury. The ATLS recommends a systematic and team approach by assessing the ABC's and providing interventions as indicated by clinical presentation.

**Table 3** Common laboratory and imaging studies

Laboratory studies	Imaging studies
Complete blood count	Chest radiography
Comprehensive metabolic panel	Pelvic X-ray
Amylase/lipase	Computed tomography (CT) head
Coagulation profile	CT cervical spine
Type and screen/cross	CT chest
	CT abdomen/pelvis
	Extremity radiographs

## Chapter 10.2

# Drowning/Submersion Injuries

Arun Bansal

Drowning is defined as “a process resulting in primary respiratory impairment from submersion/immersion in a liquid medium.” Term *drowning* should be used regardless of the outcome. It also specifically recommended that terms, such as *near-drowning*, *silent drowning*, *wet drowning*, *secondary drowning*, *passive drowning*, and *dry drowning* be abandoned. Uniform way of reporting a drowning event is by Utstein template of reporting. This allows standardization of the event and comparison.

## INCIDENCE

Drowning is an important cause of death all over the world. As per the World Health Organization (WHO), 0.7% of all deaths worldwide or more than 500,000 deaths each year are due to unintentional drowning. Toddlers and adolescents are common age groups among children who are more vulnerable. Drowning is a leading cause of death worldwide among boys 5–14 years of age. In young children, drowning event occurs more at home. Infants drown in bathtubs most frequently. Most of the events occur due to lack of adult supervision. Toddlers usually drown in swimming pools. Adolescents are more adventurous, thus, drowning events are more common in natural bodies of water. Intoxication may also play a role. Certain pre-existing medical problems may lead to increased chances of drowning, like in a child with seizures, arrhythmias, long QT syndrome, etc. Main risk factors for drowning are age less than 14 years, male sex, alcohol abuse, low income, poor education, rural residency, risky behavior, and lack of supervision.

## PATHOPHYSIOLOGY

The primary physiologic effects of drowning are due to hypoxic-ischemic and reperfusion injuries. Long-term neurologic sequelae of drowning occur almost exclusively among patients who have drowning-associated asphyxial cardiac arrests. Patients who do not experience cardiac arrests rarely have significant sequelae. Drowning-associated asphyxia is caused by laryngospasm, apnea, or pulmonary aspiration of water. This leads to hypercarbia, hypoxia, and acidosis and decreases myocardial contractility, elevate pulmonary artery and systemic vascular resistance, and produce cardiac arrhythmias.

Lung injury causes abnormal surfactant function and increased capillary endothelial permeability which leads to increased poor lung compliance, intrapulmonary shunting, ventilation or perfusion mismatch, and atelectasis which cause further hypoxemia and hypercarbia. When severe enough, this process may lead to acute respiratory distress syndrome (ARDS). As against earlier beliefs, lung injury is similar in fresh water and saltwater drowning.

The most devastating consequence of drowning and the most frequent cause of death is hypoxic-ischemic injury to the brain. The degree of central nervous system injury is related to the duration of untreated cardiac arrest, the effectiveness of initial cardiopulmonary resuscitation (CPR), and secondary cerebral injuries after resuscitation (e.g., further hypoxic episodes, inadequate cerebral blood flow, cerebral edema, and

hyperthermia). The whole drowning process, from submersion to cardiac arrest, can occur in seconds to few minutes, but sometimes in hypothermia or in ice water, the process can last for an hour.

## CLINICAL FEATURES AND MANAGEMENT

The *golden period* in the management of drowning victims is before the patient reaches hospital. Immediate rescue from water and prompt initiation of basic life support are critical for good outcomes. Time is the most important element, therefore bystander CPR is of utmost value. Unfortunately, only less than a third of the drowning victims get bystander CPR.

## Resuscitation

Hypoxic-ischemic injury during drowning results in myocardial dysfunction, which manifest clinically as shock. If left untreated, it can lead to complete cardiac arrest. Either in shock or cardiac arrest, victim may be unresponsive, apneic, and with no pulse. Prompt CPR with rescue breathing and effective chest compressions can be lifesaving. Even some bystander CPR is better than no resuscitation. Heimlich maneuver or other attempts to clear the airway of water not only are ineffective, but frequently are detrimental by inducing emesis and aspiration of gastric contents. After opening the airway with the head tilt-chin lift maneuver, two mouth-to-mouth rescue breaths should be provided. Single rescuers should provide two rescue breaths before each cycle of 30 chest compressions (please refer to Chapters on BLS, Resuscitation for the details).

Common arrhythmias noticed are bradycardia, asystole or ventricular fibrillation. Early ECG recording is therefore essential. The victim should be treated at a place where adequate facilities are available. Victim should undergo detailed evaluation and treatment upon arrival at the hospital. Focus should be rapid cardiopulmonary assessment, evidence of shock, hypothermia and associated trauma as well as for signs of neurologic and pulmonary injury.

The drowning victim may have variable symptoms ranging from no sequelae to cardiac arrest. CPR should be continued until return of spontaneous circulation or until resuscitation is futile. There are no predictors of normal neurological outcome. Good outcomes have been noticed even after 1 hour of drowning, extreme hypothermia or acidosis. Due to this, it is recommended that all victims receive aggressive care for the first 24 hours until the prognosis can be better determined.

## Cardiovascular Effects

Patients may be in shock, even after initial resuscitation. Shock could be decompensated or compensated, manifesting with tachycardia, abnormal perfusion, decreased urine output, acidosis or encephalopathy. Shock is usually because of decreased myocardial contractility following hypoxemia and acidosis. Intravascular hypovolemia due to fluid shift also contribute to decreased cardiac output. Management of shock is like any other case with shock. Patient may require fluids and inotropes.

## Hypothermia

Many reports are available in adults as well as in children about good recoveries following icy water drowning. Many factors play a role to decide about inducing hypothermia in a drowned victim. Mild hypothermia may be useful in some cases. Studies in adults suggest improved outcome with mild hypothermia in drowning victims with cardiac arrest and ventricular fibrillation. Similar

case reports are also available in children who had prolonged submersion in icy cold water. In spite of lack of evidence, mild hypothermia (32–34°C) may be a good option in children who are comatose but hemodynamically stable. This may be continued for up to 24 hours. Rewarming should be done in children with severe hypothermia (< 28°C) and in moderate hypothermia (28–32°C) with cardiovascular instability.

Rewarming is of two types, namely:

1. *Passive rewarming* This is usually done at the scene. Protect the patient from wind and cold and remove wet clothes.
2. *Active warming*
  - a. *External rewarming* This is performed with heaters or warm air, but it can lead to vasodilatation and cardiovascular instability.
  - b. *Internal rewarming* It is the gold standard, especially in children with cardiac arrest or hemodynamic instability. In the developed world, it is achieved commonly with cardiopulmonary bypass or extracorporeal life support. In developing countries, body cavity lavage (peritoneal, bladder, pleural, gastric) are alternative methods.

An important thing to note while rewarming is to prevent hyperthermia. Hypothermia reduces the electrical and metabolic activity of the brain. The rate of cerebral oxygen consumption is reduced by 5% for reduction of 1°C in temperature.

## Trauma

Accidental injuries are common in drowning while diving, boat accidents or other motor vehicle accidents. Thorough examination need to be done to look for any traumatic injuries including, brain, spine, intra-abdominal. CT scan, if needed, should be done after stabilization.

## Hypoxia-Ischemia

Hypoxic-ischemic injuries are most common in drowning patients as brain is the most susceptible organ to hypoxia. Children who are neurologically normal at admission are likely to be normal. However, children who are comatose or have altered sensorium, serial examination in the next 24–48 hours is important to predict outcome. Children, who return to normal neurological examination within 24 hours, usually have good outcome. Only factor proven to be of benefit for good outcome is on site CPR or immediate resuscitation and mild hypothermia. No benefit is seen with various medical therapies like, drugs, management of raised intracranial pressure (ICP) or its monitoring. Focus should be to prevent secondary insult like, hypoxia, hypercarbia, seizures, or hypo-/hyperglycemia.

## Pulmonary Involvement

Drowning victims may require mechanical ventilation, if they have respiratory distress. Target should be to achieve normocarbia, and normal oxygenation. Hypercarbia can be dangerous in these children as it can lead to rebound raised ICP due to increase in cerebral blood flow. Child requires continuous monitoring initially as the pathology is progressive and ventilator requirement may increase. Both, atelectasis and over-distension is detrimental. These children are usually ventilated with conventional modes of ventilation but, newer modes including high frequency ventilation may be needed as per requirement. Chest X-ray is needed in these cases to detect pulmonary involvement. Pneumonia should be suspected if there is clinical evidence along with bacteriological and

radiological evidence. But, prophylactic antibiotics have no role and are best avoided.

Pulmonary injury following drowning can lead to ARDS. It can be due to direct injury to lungs because of drowning or indirect due to pneumonia, sepsis, etc. ARDS may develop over hours or days. Diagnosis of ARDS is made as in any other ARDS case. The course of ARDS is also similar in these cases, exudative phase, fibrosing stage and resolving phase. Treatment of ARDS is also same like in any other ARDS.

## Other Organ Involvement

Significant hypoxia or cardiac arrest may cause damage to other organs or may lead to multiorgan dysfunction. Other organs to be affected are kidneys and liver. These organs may show manifestations up to 72 hours. Renal injury may present in the form of oliguria/anuria, increased renal functions or acute tubular necrosis. Presentation of liver damage may be in the form of increased liver enzymes, bilirubin, or abnormal liver synthetic functions.

Children who have significant organ involvement should be managed in Pediatric ICU. However, mildly symptomatic or asymptomatic children can be discharged after initial observation in emergency. Children with Glasgow coma scale (GCS) more than 13, normal oxygenation, normal renal and hepatic functions, and normal examination by 12 hours can be discharged and need not require admission.

## PROGNOSIS

No single factor can guide the need of resuscitation in drowning victims. Duration of drowning has been associated with outcome. However, prolong submersion in icy water has shown good outcome. Moreover, it is difficult to tell exact duration of submersion. Hence, all children should receive aggressive resuscitation at admission.

Similarly, no clinical or laboratory parameter at admission is available to predict good neurological outcome. Studies on this are lacking and need further investigation.

In children who return to spontaneous circulation, outcome improves over a period of time. Children who show significant motor improvement in first 24 hours are the ones who had no or mild neurosequelae at discharge. Children who remain comatose or have nonpurposeful motor movements show severe disability at discharge. Apart from neurodisability, children with lung injury may have chronic pulmonary disability like reactive airway disease or chronic lung disease.

## PREVENTION

Incidence of drowning incidence has declined in the last three decades, mainly due to better preventive efforts. Still, lot more is required, as more than two-thirds of the events are still preventable. Optimal preventive efforts differ as per age group. Infants and young children should enter the pool always under adult supervision. In spite of that, lapses may occur. Most childhood drowning are usually silent and the supervisor may not hear any splashing or struggle. Therefore, multiple barriers of prevention are recommended. Fencing of pool with a proper latch has shown to decrease the drowning incidence by 50–80%. Adolescents should be educated about water safety and risk of intoxication while swimming or when near any water body. Swimming lessons cannot make a child *drown-proof* under all conditions.

### IN A NUTSHELL

1. Childhood drowning is a common cause of mortality and morbidity.
2. Terms like near drowning, dry drowning, passive drowning, and dry drowning are not used nowadays.
3. Important factors which lead to drowning are age (toddlers and adolescents), lack of supervision, adventurous behavior, and use of intoxicating substances.
4. Preventive strategies are more important than post drowning care.
5. Main pathophysiology after drowning is pulmonary aspiration and hypoxic ischemic injury to brain.
6. Bystander CPR is the most important factor for good outcome and should be initiated as soon as possible.
7. Duration of submersion and hypothermia are the other important factors which can affect the outcome.
8. Mild hypothermia can be protective, but hyperthermia should be avoided.
9. Pulmonary involvement may vary from mild pneumonia to severe ARDS.
10. Pulmonary edema encountered in children after drowning is due to acute respiratory distress syndrome and not from fluid overload. It should be treated with positive end-expiratory pressure and not diuretics.

## Chapter 10.3

# Animal Related Injuries

Arun Kumar Baranwal

Animal-related injuries pose a major public health problem in children worldwide, especially in South Asia. Predominant rural population and agriculture-based economy are the major contributory factors. Changing social, demographic and economic scenario led to increase in its importance and has altered profile of such injuries. Animal-related injuries constitute 6–12% of all injuries in community-based studies from India. Numerous animals have potential to inflict injuries in children, the most important being caused by dogs, monkeys, cattle and wild animals. About 48,000 occupational fatalities were estimated to occur in India during 2006 in the farm sector alone. However, with over 1.1 crore cattle farmers and suboptimal health and safety infrastructure, the actual number of cattle-related injury associated fatalities can only be speculated. There is no empirical pediatric data on animal-related injuries in South Asian countries. Health impacts of animal-related injuries are dependent on type and health of inflicting animal, size and health of the victim, availability and appropriateness of accessible health-care infrastructure. These have significant economic impact as well in terms of cost of travel, treatment, vaccination, loss of wages and school absences, etc.

## EPIDEMIOLOGY

Animal-related injuries may be broadly classified as *small-animal bite injuries* and *large-animal-related injuries*. The causative animal and the spectrum of injuries are dependent on the kind of animal cohabitating with the human population. Living in close contact with domestic animals and often not far from wild ones is common in South Asia. India alone is estimated to house about 25 million dogs, mostly stray ones in rural and urban habitations (**Fig. 1**). An estimated 17.4 million small-animal bites occur in India every year. In a multicentric study from six cities of India over 18 months, dog bites were commonest (92%, mostly stray ones), followed by bites by monkey (3.2%), cat (1.8%), fox (0.4%) among 1,357 fresh bite injuries. Half of them were in children (age, 2–18 years), and mostly unprovoked (64.3%) and by stray animals (64.7%). Boys were attacked more often than girls (2.5:1). Another study revealed seasonal pattern of dog bite, the peak incidence being 10 weeks

**Figure 1** Cohabitation of stray dogs is common in South Asian urban and rural residential areas

following the peak stray-dog breeding period, due to maternal protective behavior of the stray dogs. In a community based study from Delhi, overall incidence of small-animal bites was 8/1000 population/year. Incidence for minor and major injuries was 2.5/1000 and 5.3/1000 respectively.

Monkey bites are the second most common small-animal bite in South Asia, which assumes significance as monkeys are supposed to be regular carriers of rabies virus. Cat bites also constitute a significant number in Indian studies on small-animal bites. Other animals inflicting bites are mongoose (in rural areas), camels (in Rajasthan and Haryana), black bear (in Himalayan territories), large cats (tigers, lions, leopards) (in wild and in various bioreserves), wild dogs, hyenas, wolves, crocodiles and other reptiles.

Cattle-farming is an important economic activity in South Asia, which is mainly based on subsistence farming with average herd size of just five animals. It leads to children being at risk of *large-animal*-related injuries due to their close social and occupational associations with them in villages and rural towns. An US study revealed that moving or herding the cattle was the most common task being performed at the time of injury. The same is likely to be true in South Asia as well, as buffalo-back riding by children is a common scene here (**Fig. 2**). Estimating the number of *at risk* children and the extent of cattle-related injuries is difficult due to lack of reporting system, occupational health facilities and safety infrastructure, despite harboring the largest number of cattle in the world. In an US based survey, half of the cattle-related injuries occurred in children less than 10 years, which is due to engaging them at younger age in agricultural work, lack of knowledge and experience of hazards associated with cattle.

An increasing incidence of wild animal-related injuries has been reported from Himalayan and sub-Himalayan regions causing mortality and serious morbidity. Intrusion of the forest, deforestation, low socioeconomic status and living near forest are the contributory factors. Many times these injuries are inflicted in forests and bioreserves or sanctuaries. Again, it is difficult to estimate the magnitude of the problem as most injuries do not come to medical attention at all.

## MECHANISMS OF INJURY AND CLINICAL FEATURES

*Small-animal bites* range from benign to serious life-threatening injuries. Dog bites include abrasions, lacerations, piercing wounds, avulsion of tissues and/or crush injury. Cat bites and rat bites are usually piercing wounds, the former often penetrate to deep tissues. For the purpose of post-exposure rabies prophylaxis, the animal bites have been categorized as given in **Table 1**. Lower extremities are involved in about half of the cases, and almost two-thirds of those patients who needed post-exposure prophylaxis had Category III bites. The risk of injury to the head, face and neck is greater in children (**Fig. 3**) compared to adults leading to increased severity, necessity for medical treatment and fatalities.

*Cattle-related injuries* can be classified based on mechanism of injury (blunt trauma versus penetrating trauma) and the injured body parts (trunk, face, extremities). Most injuries appear to be blunt trauma due to kicking or crushing type injuries, however penetrating injuries from cattle horns are also common. Horn-related injuries have a distinct pattern based on child's activity at the time of injury. Fall from back of slowly moving buffalo usually cause limb injuries, involving mostly lacerations, contusions and fractures.

*Blunt injuries* are due to high energy impact with severe crushing tissue damage, and are more common in children. These are mostly caused by kicks, other mechanisms being pushed, trapped between the animal and wall or a gate, butting and trampling. Force generated is usually sufficient to cause multiple fractures,

**Figure 2** Practice of buffalo-back riding among young children while moving or herding cattle is a common scene in Indian villages

including the skull and maxillofacial fractures, leg wounds or serious thoracoabdominal injuries involving vertebrae and ribs. Abdominal injuries are associated with intestinal contusions, visceral ruptures and even eviscerations. Fatalities are more common with the blunt injuries compared to the penetrating injuries. The less severe non-fatal injuries like fractures of extremities are more frequent than these life-threatening injuries. In an US survey on the farm animal-related nonfatal injuries among children, scrapes and abrasions were commonest (26%) injuries, followed by cuts and lacerations (18%), fractures (17%), and contusions (15%). Head and hand were the most commonly affected body parts. Corneal injuries may be caused by cattle tails or ears.

*Goring*, i.e., stabbing with horns lead to penetrating injuries, mostly affecting abdomen followed by perineum, neck and head. Mechanism involves multiple forces; initially horn penetrates usually in an upward trajectory and victim gets lifted upwards. Following this, a forceful turning of the animal's head creates rotational forces. These forces cause complex and destructive tracts with considerable visceral injury, even with seemingly small external wound. In a retrospective study of bull horn injuries among adults from Vellore (India), 61% of injuries occurred to perineum or abdomen, and wounds were directed obliquely upwards. Injuries to femoral vessels, external and internal genitalia, anus and rectum are also seen depending on the site of entry wound.

*Wild large-animal-related injuries* have a combination of cutting, penetrating and crushing wounds. These are contaminated significantly from claws and teeth of the animal. Fall of large animal on child's body along with attack with its limbs can lead to deep lacerations, penetrating and blunt injuries to skull, face, neck and trunk. Victims may have complex fractures of limbs (with/without injuries to tendons and nerves), facial bones, skull and ribs. Comminuted fractures of first and second cervical vertebrae with spinal cord injuries, trauma to major neck vessels and pharynx may complicate the problem. Camel bites are seen to be associated with maxillofacial fractures. The elephant-related injuries are peculiar due to strength of impact and larger area of body involved. These injuries usually occur in far-flung forests with considerable delay in notification, rescue of the patient and definitive care. Without urgent management, risk of disfigurement, functional loss and death is very common.

## APPROACH TO DIAGNOSIS

Management of the victim of animal-related injuries involves detail history and physical examination. A careful attention to the

**Table 1** WHO categories of bite injuries for the purpose of rabies prophylaxis

Categories	Description
Category I	Touching and feeding animals, licks on intact skin
Category II	Nibbling of uncovered skin, minor scratches or abrasions without bleeding
Category III	Single or multiple transdermal bites or scratches; licks on broken skin; contamination of mucous membrane with saliva from licks; contacts with bats

**Figure 3** Deep upper lid wound from monkey bite

circumstances surrounding the injury, e.g., type of animal (small or large; domestic or wild), provoked or unprovoked attack, place of attack, mechanism of injury (blunt, penetrating, tearing or crushing) will be clinically relevant. Time elapsed since the injury has lot of bearing on the surgical management of the wound. An unprovoked dog bite is likely to be from a rabid one. Information on drug allergies and immunization status of the child (tetanus) and animal (rabies) will be useful in treatment planning.

Type, size, location and depth of the wound should be carefully examined. Wounds should also be evaluated for presence of the contaminating material, status of underlying structures and range of motion if a limb is injured. Injury severity score or trauma and injury severity score may be used to measure injury severity in cases of large-animal-related injuries. Extent and severity of tissue destruction and risk of infection are of paramount importance in deciding the management decisions and prognosis. High index of suspicion should always be there for serious underlying bone or soft-tissue injury.

A detailed diagram of injury should be made in the patient's medical record for prognosis, follow-up and medicolegal issues. Radiographs of skull, cervical spine, chest, abdomen and extremities should be obtained as clinically indicated. It will help in detecting foreign material as well. Victims of large-animal-related injuries should undergo detail radiological survey to detect fractures. Patients with injuries to face and/or head have high likelihood of fracture and/or penetrating injury of the skull. A computed tomography may help in formulating a comprehensive management plan.

## COMPLICATIONS

Rabies is the most significant complication of animal bite injuries; it can also occur with direct contact of saliva with mucosa or fresh skin wounds (refer to chapter on rabies in Section 31, Viral Diseases). In fact, India has maximum human rabies cases in the world, and estimated to contribute about 20,000 fatalities per year, which is likely to be a gross underestimation for lack of organized system of rabies surveillance. Although all age groups are susceptible, it is most common in children less than 15 years of age. Infection is the most common complication of dog bites. Decision to do microbial studies of bite wounds depends

on the time elapsed since bite, depth of wound, presence of contamination and clinical evidence of infection. As infection rate for bite wounds presenting to health-care facilities within 8 hours is small (2.5–20%), it need not to be cultured unless wounds are deep, extensive, contaminated, and/or there are early signs of infection, or patient is immunocompromised. Infection rate in monkey bite and cat bite wounds is high ( $\approx 50\%$ ) even in cases receiving early medical attention, these wounds should always be cultured. All small-animal bite wounds presenting after 8 hours should always be cultured. Large-animal-related penetrating injuries and wild animal bites may involve resistance from the victim, which drives mud, grass and other contaminating material into the wounds. Infection rate is dependent on multiple factors including timeliness of and level of access to health-care and socioeconomics. Risk for infection is more with crush injuries, deep puncture wounds, and wounds to the hand. Thus, these wounds should always be cultured.

Tetanus is an important consideration in all animal-related injuries, especially in large-animal-related ones due to heavy contamination, more so in the agricultural setting. It assumes significant importance due to poor coverage of and lack of awareness about the 10-year booster immunization against tetanus.

## MANAGEMENT

Management of the animal-related injuries involves different strategies for *small-animal* bites and *large-animal*-related injuries.

### Management of Small-Animal Bites

Prompt treatment of all bites and abrasions is of the utmost importance. The purpose is to remove as much rabies virus (if there is any) as possible from the site of inoculation before it gets absorbed on nerve endings. Wound management is of maximal value when applied immediately after bite (within minutes if possible); however it must be done even after several hours or days of the bite. Immediate wound treatment is shown to reduce potential of rabies by about 80% in experimental studies. The wound management comprises of following:

**Wound toileting** Immediate flushing and washing the wounds, abrasions and the adjoining areas with plenty of soap and water, preferably under a running tap for at least 15 min. If soap is not available, simple flushing of wounds with plenty of water may be enough. In case of punctured wounds, catheters should be used to irrigate wounds.

**Chemical treatment** After toileting whatever residual virus remains in the wounds should be inactivated by irrigation with Savlon, Dettol, povidone iodine, tincture, or alcohol (70%).

**Suturing** Primary suturing should be avoided to prevent additional trauma which may help spread rabies virus into deeper tissues. If suturing is necessary, it should be done 24–48 hours later, applying minimum possible stitches, under cover of local rabies immunoglobulin infiltration. Topical antibiotics and antitetanus measures should be ensured if indicated.

**Systemic antibiotics** All Category II and III bite injuries from dogs, monkeys, cats and rats need systemic antibiotics regardless of evidence of infection. A varied mix of aerobic and anaerobic bacteria colonizes oral cavity of the biting animal, and thus most bite wound infections are polymicrobial. Oral versus parenteral route may be guided by the severity of wound, presence and degree of local infection and/or systemic toxicity, and immunocompetence of the victim. Co-amoxiclav may be preferred for empirical oral treatment. Azithromycin may be an alternative for penicillin sensitive patients, as it is effective against

both aerobic and anaerobic bacteria. Erythromycin, clindamycin and co-trimoxazole are not useful in small-animal bites for lack of relevant antimicrobial coverage.

**General management** Patients with bites on the limbs should be asked to keep it elevated for about a day or two, or until edema has subsided. Wounds of the hand should be immobilized in functional position for about 3–5 days. All bite victims need follow-up for re-evaluation of the wounds within 2–3 days.

### Management of Large-Animal-related Injuries

Management approach for victims of large-animal-related injuries is similar to that of victims of road traffic injuries. Life support measures, detailed examination, multispecialty consultation, coordinated planning and relevant surgical procedures need to be instituted at the earliest in time critical manner to minimize morbidity and mortality. Following are the principles of the management:

**Resuscitation and stabilization** A high degree of suspicion to have major and multiple traumas is required. The initial primary goal is meticulous resuscitation and optimal stabilization as per the guidelines of pediatric advanced life support and advanced trauma life support. Management should be initiated at the site of attack itself with the best possible measures to stop bleeding, administer fluid and immediate transport to the nearest secondary or tertiary center as per the available health-care infrastructure. Once at hospital, primary survey of the whole body needs to be performed. Resuscitation and stabilization of trauma patients are detailed in Section 10.1, and should be followed for large-animal-related injuries as well.

**Initial wound management** After initial resuscitation, thorough attention to local wound care and exploration are required. Wounds are usually heavily contaminated, and thus appropriate material should always be obtained for culture. Management consists of cleaning and vigorous irrigation with liberal amounts of saline using a syringe. Antibiotic-containing solutions are not recommended for irrigation. Puncture wounds should gently be irrigated with a syringe and a catheter or blunt-tipped needle; however high-pressure irrigation should be avoided. Generous debridement of devitalized tissue and removal of all foreign material is the mainstay of surgical management. Fluctuant areas need to be incised and drained. The thirty-five percent of bull horn injuries reported from Vellore (India) required extensive surgical intervention. About half of the primarily closed wounds developed infection in this study, while it was seen only in 6% of the secondarily closed wounds. Thus delayed and/or partial closure of the wounds is considered as standard of care. However uncomplicated, clinically uninfected lacerations on face, head and neck, presenting within 6 hours, thoroughly irrigated and debrided, primary closure is preferable because of generous blood supply to this region. Broad spectrum antibiotics including anaerobic coverage are indicated in all penetrating wounds pending the culture results. Prophylaxis against tetanus and rabies should be given as indicated.

**Definitive surgical management** These injuries are usually complex and thus a well-coordinated multidisciplinary approach including pediatrician and/or pediatric intensivist, orthopedic surgeon, neurosurgeon, maxillofacial surgeon, ophthalmologist, plastic surgeon, microbiologist and psychiatrist. Acceptable cosmetic and functional results may be achieved and mortality may be prevented with timely and aggressive interventions. Cattle-related blunt trauma injuries frequently require thoracotomy, laparotomy and craniotomy as well as fracture management. For penetrating wounds, there should be a low threshold for evaluation of wounds under general anesthesia and laparotomy when abdomen is injured.

## PREVENTION AND PUBLIC HEALTH MEASURES

### Dog Bites

Despite dog bite is a public health problem and the major source of rabies in the South Asian countries, we do not have any comprehensive dog bite control program. Some organizations are involved in control activities in isolation however without intersectoral coordination. The most logical and cost-effective approach is swift mass immunization program for stray dogs, in the shortest possible time, of at least 70% of the entire dog population of the area (for herd immunity) combined with long-term aim of elimination of the stray dogs. However, in the meanwhile, following strategies may be employed:

- Training of health-care professionals (including doctors) about animal bite management.
- Timely and adequate management of all animal bite victims.
- Vaccination of the pet and stray animals through potent vaccines at regular intervals through active community participation.
- Creating awareness about timely and adequate postexposure management of all animal bites in the community.
- Research to identify interventions required to manage population, habitat, movement, behavior and demography of dogs.
- Dog birth control through sterilization.
- Census, licensing and obligatory registration of all domestic dogs in the community.
- Restrain of dogs in public places.
- Immediate destruction of dogs and cats bitten by rabid animals.
- To implement a proper waste management.
- To stimulate the research community to perform operational research to help policymakers focus on reducing the potential of animal bites in the community as an expected outcome.
- Young children should never be left unattended around any dog, and need to be supervised closely.
- Children need to be taught to respect animals, to avoid stray ones, and to be aware of their potential to cause injuries.

Incidence of dog bites were significantly reduced after implementation of stray dog sterilization program in Jaipur during 2003–2011, by reducing the overall population of the stray dogs as well as by reducing the maternal protective behavior resulting from the lack of puppies. An organized animal injury (and thus rabies) control program has started taking shape in Tamil Nadu, the same needs to be widened on national level.

### Monkey Bites

As for dogs, the population control may be the ideal and ultimate goal. However, following strategies may help avoid monkey attacks and bite injuries:

- Monkeys consider showing teeth as a sign of threat and aggression. Smiling at them may provoke an unnecessary attack, and thus should be avoided.
- The primary reason that children are bitten by monkeys is because they do not drop something that a monkey has grabbed. Children should be advised to let the things go as soon as a monkey grabs something, chances are they will examine it and drop it anyway.
- Children should be instructed not to offer feed to monkeys, it will attract many more and likely to attack in group.

### Cattle-related Injuries

Public awareness program based on the findings of operational research on interventions aiming to reduce cattle-related injuries and to limit its impact in the existing occupational and health-care scenarios may be helpful. Parents in farming community may be advised to consider the age, physical and mental abilities of the child while assigning a job to him or her for its safe accomplishment. Efforts to educate and create awareness among children and their parents about cattle handling skills, recognition of animal behaviors, danger signs and mechanisms to avoid them can reduce incidence of injury. Adequate supervision of children in their farm activities may avert many mishaps. Wearing protective gear while herding and moving the cattle or back-riding are other preventive measures. North American Guidelines for Children's Agricultural Tasks have been developed to help guide child safety in agricultural sector and to identify which tasks can safely be performed by children of various ages and skills. These guidelines may be worked upon for their possible adaptation in South Asian countries to prevent cattle-related injuries to children.

Many cattle-related injuries are patterned, predictable and preventable. Thus a systematic approach involving workable modifications in the child, the cattle and the environment relevant to the existing socio-economic and health-care scenarios is desirable.

#### IN A NUTSHELL

1. Animal-related injuries may be broadly classified as *small-animal bite injuries* and *large-animal-related injuries*.
2. Dog bite is the most common injury followed by those from monkeys, cattle and wild animals.
3. Rabies is the most significant complication of animal bite injuries; India contributes maximum human rabies cases in the world. Tetanus is the next most important in unimmunized children.
4. Wound management is of maximal value when applied immediately after bite (within minutes if possible); however it must be done even after several hours or days of the bite.
5. All Category II and III bite injuries from dogs, monkeys, cats, and rats need systemic antibiotics regardless of evidence of infection.
6. A comprehensive dog bite control program is the need of the hour.

## Chapter 10.4

### Pediatric Burns

K Mathangi Ramakrishnan, V Jayaraman,  
T Mathivanan, V Srinivasan

The wide age range of children makes the study of epidemiology of pediatric burns very unique. Some centers are reporting suicidal burns in adolescents. These suicides are usually due to failures in examinations and emotional involvements. An update in epidemiological survey needs to be done at least once in 5 years.

#### EPIDEMIOLOGY AND ETIOLOGY

Epidemiological data provides vital information and helps us to plan preventive strategies. The important areas to be analyzed are the total number of cases burnt, place of injury, type of residential area from where they come, seasonal variations, apart from age, percent of surface area burnt, depth and site of burns. These ultimately will help estimate accurate mortality and morbidity. **Table 1** shows the profile of Pediatric Burns at Kanchi Kamakoti CHILDS Trust hospital, Chennai over a period of 20 years. The major etiology of burns is due to flame, scalds, electrical injury, chemicals and radiation.

#### EMERGENCY ROOM MANAGEMENT OF MAJOR BURNS

Although burn injuries that cover 25% or more of the body surface area (BSA) are considered as *major burns*, any burn injury more than 10% should be treated similarly. Majority of childhood burns are evaluated and resuscitated initially in the emergency department. Mortality in burn injuries is to a large extent influenced by the initial care given in the emergency department. Burn victims rarely die due to the burn, but this can occur because of associated trauma, carbon monoxide (CO) inhalation or airway compromise.

#### Initial Steps in the Management of a Major Burn

The burn injury must not distract from a sequential assessment otherwise serious injuries can be missed easily. A methodical initial approach to burn treatment is needed regardless of the etiology of the burn and is essential to prevent mortality and includes: primary

survey; investigations; pain management; secondary survey and focused history; and safe transfer to a specialized burns facility.

#### Primary Survey—ABCDE

The primary assessment, investigation and treatment of a patient with severe burns should be a continuous and integrated process. A modified *Pediatric Advanced Life Support* is performed with particular emphasis upon airway and breathing.

**A—Airway with cervical spine precautions** It is important to ensure and maintain an adequate airway, taking precautions for cervical spine stabilization and to provide humidified oxygen by mask or endotracheal intubation. Fire burns often have an inhalational and airway component. If a patient's physical examination and history indicate airway injury, a thorough assessment of the airway and placement of an advanced airway if required is indicated. It is mandatory to stabilize the cervical spine if the history and clinical examination are suggestive of injury (**Box 1**).

#### BOX 1 Symptoms and signs of respiratory tract injury

- Altered consciousness
- Stridor/hoarseness/harsh cough
- Tachypnea/dyspnea
- Singed eyebrows/eyelashes
- Soot in the nostrils/sputum
- Dysphagia/deep burns of face/neck/upper chest
- Expiratory rhonchi.

Children are especially prone to airway compromise due to their narrower airway and any mucosal swelling or fluid accumulation causes a comparatively larger reduction in airway diameter. In addition, there is a high incidence of occult upper airway obstruction caused by enlarged adenoids and tonsils, laryngomalacia and reactive airways in children. Intubation is preferred before airway closure rather than in the emergency setting once the airway has been lost. Stridor is a late sign. Supraglottic airway injury is usually the result of direct thermal injury.

Bronchoscopic visualization of the airway is recommended for assessment of subglottic airway injury, directly visualizing the upper airway with a laryngoscope provides a lot of information about the nature and extent of injury. If blisters are seen in the oropharynx or oral mucosa, or the mucosa appears dry and erythematous, one should anticipate airway compromise. Edema of the airway may not be apparent until 48 hours after a burn. If the physician waits until obvious compromise, results may be

**Table 1** Profile of Pediatric Burns at Kanchi Kamakoti CHILDS Trust Hospital (September 1992–December 2013)

%BSA	Age in years		Sex		Type of burns			
	0–9	10–18	Male	Female	Scalds	Flame	Electrical	Chemical
0–10%	557	26	335	248	510	57	10	7
11–20%	197	8	95	110	176	24	4	0
21–30%	92	5	49	48	72	17	8	0
31–40%	53	8	35	25	41	11	8	0
41–50%	12	2	6	8	12	2	1	0
> 50%	8	5	6	8	7	3	3	0
Total	919	54	526	447	818	114	34	7

Abbreviation: BSA, body surface area.

catastrophic and intubation can be extremely difficult. During intubation, it is important to have various size endotracheal tubes available and anticipate a narrowed airway. However, it is important to remember that unnecessary intubation and sedation can worsen the situation, so a decision to intubate must be made carefully.

Patients in whom complete respiratory obstruction have already occurred or intubation is unsuccessful, immediate cricothyrotomy or *mini* tracheostomy is required followed by formal tracheostomy. Also the emergency care provider must remember to place a nasogastric or orogastric tube in those patients who are comatose as they tend to have gastric dilatation, which can interfere with ventilation or cause aspiration into the airway.

**B—Breathing** All burn victims should receive 100% oxygen through a nonrebreathing mask on presentation. Respiratory system injury involving the lungs and chest can occur due to an inhalation, aspiration or direct thermal, electrical or chemical injury. It is important not to rely on chest radiograph because it is often normal at initial presentation. Respiratory system involvement below the glottis can cause problems in breathing and can have any of the following manifestations:

- Lower airway edema and irritation as a result of chemicals or toxins such as smoke inhalation leading to chemical pneumonitis.
- Carbon monoxide poisoning (which cannot be detected by pulse oximetry) can occur in all patients who are victims of house or indoor fires.
- Blast lung injury or penetrating injuries causing pneumothorax can be the initial presentation.
- Circumferential burns to the chest, which can cause respiratory compromise.

**C—Circulation** The greatest amount of fluid loss is in the first 24 hours after injury and there is a shift of fluid from the intravascular to interstitial compartment in the first 12 hours, hence any fluid given during this period will rapidly leave the intravascular compartment.

- Intravenous access should be obtained immediately in intact skin. If necessary though, catheters may be placed through burned skin or intraosseous access can be used.
- The most serious complication that can occur during intraosseous administration of fluids in a burn victim is the inadvertent administration of fluid into the muscle compartments, leading to dangerously high pressures.
- Cardiac assessment in the burned child begins with the assessment of peripheral, followed by the central pulses. It is important to remember that full-thickness burns to extremities can cause a tourniquet effect making assessment of perfusion difficult. The color of skin and capillary refill in nonburned sites can be utilized, to assess for adequacy of perfusion.
- Vital signs may be difficult to obtain since burned extremities may impede the ability to obtain a blood pressure reading by a sphygmomanometer. In these situations arterial lines, particularly femoral lines, can be placed to monitor continuous blood pressure readings.

**D—Disability** Neurological disability is assessed using alert, voice, pain, unresponsive (AVPU) or Glasgow Coma Scale. Altered sensorium may be due to hypoxia, hypovolemia or dyselec-trolytemia and sepsis if the patient presents late to the emergency room.

**E—Exposure** This involves a detailed examination of the patient after the initial stabilization of airway, circulation and disability.

The patient should be examined from head to toe, including the back for an accurate estimate of the burnt area. Associated injuries should be identified. Care should be taken to avoid hypothermia. Photographs should be taken if possible without compromising patient care whenever possible.

### Secondary Survey

This is done after primary survey and initial stabilization of the patient and involves assessment of the burnt area and concomitant injuries. A history should be elicited—the quickest way is to get an **AMPLE** history which includes **A**llergy history, **M**edications, **P**roblems, **L**ast meal time and the **E**vent (the mechanism of the burns and treatment received so far).

### Focused History in Burns

The most accurate description of events leading to the burn injury can be taken first hand from those who accompany the child in the emergency room. It should include:

- Type of agent that caused the burn (flame, liquid, electrical, chemical)
- Risk of inhalational injuries (burns in a closed space)
- If there was any explosion
- Time of injury and contact with energy source
- Risk of concomitant injuries (e.g., fall from height)
- Time and nature of cooling, first aid and fluid resuscitation given.

### Assessment of Total Body Surface Area Burnt

This is estimated using one of the following methods. Erythema is not included in estimation of burn area.

#### The Wallace Rule of Nines (Fig. 1)

The Wallace rule of nines and palmar surface do not provide accurate estimations but provide a rapid assessment in situations where charts are not available.

#### Lund and Browder Chart (Fig. 2)

It illustrates the method for calculating the percentage of BSA affected by burns in children. This chart provides an accurate estimate of burned surface area in children and can be used if available in the emergency room also.

### Depth of Burns

Burn depth is described as superficial, partial thickness or full thickness (**Figs 3A to D**).

- Superficial—erythema and pain, no blisters.
- Partial thickness—red or mottled. Deep partial thickness—edematous skin with severe erythema.
- Full thickness—dry, dark appearance and leathery and may involve underlying structures including tendon, nerves, muscle, or bones.
- Deep burn needs surgical attention immediately. After escharotomy of dead tissue is done, patient's own skin or stored skin from skin bank can be used to cover the defect. This heals in 2 weeks.

Escharotomy should be done to relieve circumferential deep burns (**Figs 4A to C**).

### Fluid Resuscitation in Major Burns

#### Indications for Intravenous Fluids

- All burns of more than 15% body surface area (BSA) require intravenous fluid resuscitation to maintain adequate tissue perfusion.

**Figure 1** Wallace rule of nines

Source: Reproduced with permission from Shehan Hettiaratchy. ABC of burns. Initial management of a major burn.

- All inhalational injuries whatever the BSA require venous access to control fluid intake.
- High tension and electrical injuries need venous access for forced alkaline diuresis to avoid myoglobinuric renal damage in case of muscle injury.

### Calculation of Intravenous Fluids in Major Burns

Fluid resuscitation in the first 24 hours is based on the modified Parkland formula.

#### Parkland formula:

Total fluid requirement in 24 hours (given as Ringer lactate infusion) =  $3 \text{ mL} \times \text{total burn surface area (\%)} \times \text{body weight (kg)}$

50% given in first 8 hours

50% given in next 16 hours.

Children receive maintenance fluid in addition, at hourly rate of:

4 mL/kg for first 10 kg of body weight plus

2 mL/kg for second 10 kg of body weight plus

1 mL/kg for more than 20 kg of body weight.

#### End point:

Urine output of 1.0 mL/kg/h in children.

The starting point for resuscitation is the time of injury and not the time of admission, hence any fluid given before admission should be deducted from the calculated requirement.

### Problems with Fluids in Children

- A burn that is 15–20% total body surface area (TBSA) can produce hypovolemic shock unless appropriately managed with crystalloid fluid replacement. Isotonic saline, most commonly lactated Ringer solution 10–20 mL/kg/h is initially infused until proper fluid replacement can be calculated. Large volumes of fluid are needed for proper resuscitation because only 20–30% of the isotonic fluid remains in the intravascular space.
- Controversy exists over the use of colloids for maintaining intravascular volume, however some resuscitation regimes use colloids if the burn is more than 85% of BSA, although it is usually administered (to replace the protein loss) after the first 8 hours as the capillary leak begins to shut down. Thus, it is necessary to appropriately calculate the extent of the burn and effectively fluid resuscitates each patient individually.
- If the patient is hypotensive, the emergency physician must be aware that it may be due to delayed presentation, cardiac dysfunction or occult blood loss and has to be managed appropriately.
- Children weighing less than 20 kg may develop hypoglycemia and should have a 5% dextrose-containing solution administered at a maintenance rate, along with the calculated volume of fluid necessary for resuscitation.

Area	Age 0	1	5	10	15	Adult
A = ½ of head	9½	8½	6½	5½	4½	3½
B = ½ of one thigh	2¾	3¼	4	4½	4½	4¾
C = ½ of one lower leg	2½	2½	2¾	3	3½	3½

**Figure 2** Lund and Browder chart for percent total body surface area burn. Be clear and accurate. Do not include erythema.

Abbreviations: PTL, partial-thickness loss; FTL, full-thickness loss.  
Source: Reproduced with permission from Shehan Hettiaratchy. ABC of burns. Initial management of a major burn.

**Figures 3A to D** Depth of burns. (A) Superficial; (B) Partial thickness; (C) Deep partial full thickness; (D) Deep burns

Figures 4A to C Escharotomy

- Catheterization and hourly measurements of urine volume are mandatory in all children with more than 10% burns.
- The color of the initial urine in patients with severe flame or high voltage electrical burns may be black, indicating hemoglobinuria or myoglobinuria, or both. This necessitates monitoring for subsequent renal dysfunction.
- It is imperative to avoid overaggressive resuscitation, particularly in small children due to the risk of pulmonary edema. This is especially important in patients who have a concomitant inhalation injury causing increased pulmonary vascular permeability.
- Because pediatric burn victims are also prone to hypothermia caused by the loss of integument, fluids administered in the emergency should preferably be warmed.

### Important Issues not to be Overlooked in an Emergent Situation

- Identifying the type of burn as thermal, chemical, electrical or radiation is essential because interventions must be appropriately tailored to the underlying cause.
- Accurate documentation of the burn location (such as ophthalmic, hand, face, inhalation, soles, or perineum) is essential for follow-up and specialist referral/consultation.
- Detailed documentation of components of the history including past medical history, medications, and allergies.
- Proper documentation from a medicolegal point is imperative and all health-care personnel are obligated to contact appropriate law enforcement and protective services if they suspect the burn was intentional.
- Intravenous antibiotics are not recommended in the initial treatment of most patients with burns, as it may increase the chance of colonization with more virulent and resistant organisms.

### INHALATION INJURY

This type of burn does not take place often in young children. During mass casualties, the people affected will include children and adolescents. Inhalation injury in burns includes: (a) thermal injury to upper airway; (b) asphyxiations in major fire accidents; and (c) smoke inhalation injury.
